YOSEMITE FALLS—HIGHEST IN THE WORLD—(YOSEMITE LODGE IS AT FOOT OF FALL)

JANUARY · 1922

Vol. XX. No. 1 $4.00 a Year

California State Journal of Medicine

OWNED AND PUBLISHED MONTHLY BY THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

Entered at San Francisco, California, as Second-Class Matter

BUTLER BUILDING, 135 STOCKTON STREET, SAN FRANCISCO

EDITOR AND SECRETARY - - - - - - - - - W. E. MUSGRAVE, M. D.
MANAGING EDITOR - - - - - - - - - - CELESTINE J. SULLIVAN

MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

JOHN H. GRAVES, San Francisco — President
ALFRED C. REED, San Francisco — First Vice-Pres.
H. G. BRAINERD, Los Angeles — President-Elect
JOSEPH CATTON, San Francisco — Second Vice-Pres.
W. E. MUSGRAVE, San Francisco — Editor and Secretary
CELESTINE J. SULLIVAN — Managing Editor

COUNCILORS

FIRST DISTRICT — San Diego, Riverside, Orange, San Bernardino and Imperial Counties.
P. M. CARRINGTON, San Diego
(Term expires 1924)

SECOND DISTRICT—Los Angeles, Santa Barbara, Ventura and Kern Counties.
WM. H. KIGER, Los Angeles
(Term expires 1922)

THIRD DISTRICT — San Luis Obispo and Monterey Counties.
T. C. EDWARDS, Salinas
(Term expires 1924)

FOURTH DISTRICT — Fresno, Kings, Tuolumne, Merced, Mariposa, Madera and Stanislaus Counties.
D. H. TROWBRIDGE, Fresno
(Term expires 1924)

FIFTH DISTRICT — Santa Clara, San Mateo, San Benito and Santa Cruz Counties.
F. H. PATERSON, San Jose
(Term expires 1923)

SIXTH DISTRICT—San Francisco County.
C. G. KENYON, San Francisco, Chairman
(Term expires 1922)

COUNCILORS AT LARGE—
O. D. Hamlin, Oakland (term expires 1922); Réne Bine, San Francisco (term expires 1923); Geo. H. Kress, Los Angeles (term expires 1923); Wm. T. McArthur, Los Angeles (term expires 1923); Saxton T. Pope, San Francisco (term expires 1924); C. Van Zwalenburg, Riverside (term expires 1923).

SEVENTH DISTRICT — Alameda, Contra Costa, San Joaquin and Calaveras Counties.
EDW. N. EWER, Oakland
(Term expires 1923)

EIGHTH DISTRICT—Sacramento, Amador, El Dorado, Alpine, Placer, Nevada, Yuba, Sutter, Sierra, Yolo, Butte, Plumas, Lassen, Mono, Inyo, Glenn, Colusa, Tehama, Shasta, Modoc and Siskiyou Counties.
J. H. PARKINSON, Sacramento
(Term expires 1922)

NINTH DISTRICT — Marin, Sonoma, Lake, Mendocino, Solano, Napa Del Norte, Humboldt and Trinity Counties.
JAMES H. McLEOD, Santa Rosa
(Term expires 1923)

VOL. XX JANUARY, 1922 NO. 1

EDITORIALS

THE NEW YEAR

Our successes and failures of 1921 as individuals and as organizations, whatever they may be, are history, and we stand upon the threshhold of a New Year. During the coming year, the State Medical Society ought to make a great deal of progress in the advancement of the cause of better medicine. As an organization we will be successful exactly in proportion as we are able to secure the co-operation and support of individual members. We ask and urge that every member of the State Society give something of his time and of his means toward the betterment of his own organization.

Members are asked to bear in mind particularly that continuity of medical and indemnity defense protection and continuity of membership requires that the 1922 dues be paid on or before March 1, 1922.

County secretaries are urged to mail promptly before the 10th of each month their monthly reports to the State Society. The splendid co-operation of many secretaries in this respect is reflected in the county news columns of the JOURNAL. Some secretaries have not yet established the habit of completing and forwarding these reports and in consequence their societies and their members do not receive published credit the JOURNAL is willing and anxious to give them.

County secretaries are also requested and urged to familiarize themselves with the proceedings of the semi-annual conference of state and county officers held in San Francisco September 24, 1921, and published in the November number of the JOURNAL.

County secretaries are also requested, at the earliest possible moment, to furnish names of the officers of their societies for 1922, including the council and including particularly and specifically the names and addresses of delegates and alternates to the State meeting.

Officers in particular and members in general of local societies could render material assistance to their own organizations and the state organization by accepting suggestions contained in the JOURNAL and obviating the necessity of time and expense in more direct and more personal communications. Co-operation in this feature of our work is urgently requested of all and particularly of all secretaries.

The secretary of the State Society wishes every member of the organization a Happy New Year, and asks as one of our New Year resolutions that we all make a special effort to do everything in our power to advance the cause of better medicine during the coming year.

THE PHYSICIAN'S FAMILY

The conscientious physician devotes his time and thought to one thing—his profession. He has little time to study investments and the accumulation of wealth, and too often pays, and pays heavily, for his enforced lack of business training.

But more than that—his family pays. Accustomed to that standard of living demanded by his profession, they are poorly fitted to carry on in the event of his untimely death.

When a merchant, manufacturer, farmer or other person whose life has been devoted to personal interests dies he usually leaves that which has a realizable cash value—either ownership of a business or an interest in it. In either case an income is available for his family.

But when the physician passes away, usually he leaves a few books and instruments, with perhaps some bills receivable and possibly a good-will that has little money value.

Death ends all, so far as the family's income from his profession is concerned; and frequently old age or earlier physical impairment, or mental exhaustion, ends his earning power and puts him and his family into a hard predicament.

There is no class by whom the help of life insurance is more urgently needed than by men of the medical profession. No other thing can take its place—no other investment can be made that will, even in a small measure, operate as a substitute for the earning capacity of the medical man after his passing.

Is your family amply protected? Or have you been lulled to a false sense of security?

Arrange your family's welfare *while you can.* Any substantial life insurance company will advise you wisely.

ORIGINAL ARTICLES

PROLAPSE OF THE UTERUS WITH RECTOCELE AND CYSTOCELE; AND END RESULTS OF VARIOUS OPERATIONS.*

By ALFRED BAKER SPALDING, M. D.,
San Francisco.

From the Women's Clinic of the Stanford University School of Medicine.

Although many of the best operative procedures for uterine prolapse have been devised by American gynecologists, very few satisfactory reports of the late results following these operations can be found in the American literature. Goffe,[1] in 1912, reported the conditions found in twenty-four patients that he examined personally from two to seven years after his operation. Watkins[2] reported the results obtained in sixty-eight cases operated upon by the interposition method since 1905; and recently Clark[3] has summarized a questionnaire sent to eighty-four patients on whom he had operated for prolapse at least one year previously. To me these reports are disappointing, because I believe such reports should include a statement of symptoms and conditions present before operation, the type of operation done for cure of the conditions, and a full report of complications encountered at the time of operation, or during convalescence. Ultimately, these patients should be questioned and examined in the clinic at periods some months or years after operation and a clear statement of symptoms and the condition of rectocele, cystocele, and prolapse noted.

For many years the Women's Clinic at Stanford University School of Medicine has been interested in comparing the curative value of various operations proposed for the relief of marked conditions of prolapse of the uterus associated with cystocele and rectocele. Fairly complete histories have been taken in most cases and very extensive descriptions have been written of the operations performed. The post-operative conditions during the convalescent stay in the hospital have also been noted in the histories.

After leaving the hospital, this group of patients has been followed by the Social Service Department and re-examined by the clinical staff for periods varying from three months to eight and one-half years after operation; and, although from a statistical point of view the number may seem small, the facts obtained by this follow-up method are most instructive. It is by studying critically such a series as this that better technic has been developed in the clinic, and it is hoped that a full presentation of the difficulties encountered in this special branch of pelvic plastic surgery will be of interest to others treating women suffering from this most distressing obstetrical ailment.

From July 1, 1912, to January 14, 1921, seventy-six patients with uterine prolapse have been operated upon in the Women's Clinic of the Stanford University School of Medicine. Seventeen patients were treated by interposing the uterus under the bladder according to the technic described by Watkins[2] and others[4]; seventeen by transplantation of the sacro uterine ligaments from the posterior to the anterior surface of the cervix, as described by Jellett[5]; twenty-four by vaginal panhysterectomy, with fixation of the bladder to the broad and round ligaments, as described by Goffe[6]; twelve by vaginal supravaginal hysterectomy, as described by Spalding[7]; one by vaginal supravaginal hysterectomy, as described by Vineberg[8], and five by various methods of anterior colporrhaphy.

All the patients in this series had cystocele and sixty-eight had rectocele. The cervix was lacerated in fifty-two of the patients, was eroded in thirty-eight, and hypertrophied in fifty-one. The uterus was retroverted in fifty-one patients, was prolapsed to the vulva in twenty-six, through the vulva in sixteen, and presented outside the vulva with cystocele and rectocele in thirty-four patients.

The average age of the patients was forty-three years, the youngest being twenty-five and the oldest sixty-nine. There was an average of slightly over five pregnancies to each patient, with an average of four para. Prolapse followed with some patients after a single confinement, the largest number of children being twelve. Of the seventy-six patients, sixty-four had had spontaneous confinements and thirty-eight had had spontaneous abortions. Only twelve gave a history of operative deliveries and ten of induced abortions.

The chief complaint with fifty-nine patients was "falling of the womb," although thirty-two mentioned backache; twenty-eight, constipation; twenty, headache; fifteen, menstrual disturbances; fourteen, cystitis; thirteen, incontinence of urine, and ten, pain in the lower abdomen, as associated disturbances.

In all but one case, some type of perineorrhaphy was done, and in six of the more recent cases the rectum was supported by a more extensive proctopexy. In somewhat less than half the cervix was repaired either by amputation or trachelorraphy. With a few patients also such operations as hemorrhoidectomy, herniotomy, tightening the bladder sphincter, salpingectomy, oophorectomy, appendectomy, myomectomy and abdominal uterine suspension were done.

Pathological examinations were made in each case, with the result that thirty-two showed chronic cervicitis; twenty-one, endometritis; fourteen, myoma or adenomyoma of the uterus; twelve, metritis; six, salpingitis; three, cyst of the ovary; two, oophoritis, and one, a pre-cancerous condition of the cervix. This last patient showed very marked epithelial proliferation in an ulcerated cervix, but no actual invasion of the tissues could be demonstrated.

Forty-five patients developed a fever of 101° at some time during their convalescence and forty-two had a rise in pulse rate of over 100 during

*Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

the first twenty-four hours following operation. Of the post-operative complications met with, one of the early vaginal hysterectomies had a severe post-operative hemorrhage; two developed a pelvic hematoma; one, pneumonia; two, vesico-vaginal fistulae; one, pelvic abscess, and six, local perineal infections. The two patients with fistula were apparently cured by a second operation, although one of the patients returned a year later with stone in the bladder. One patient died of peritonitis after a vaginal hysterectomy, due to an overlooked streptococcus cystitis which had followed an attack of acute streptococcus angina shortly before coming to the clinic for operation, and one patient died of shock following an apparently simple vaginal supravaginal hysterectomy. The remaining seventy-four patients left the hospital after an average convalescence of twenty days.

Thirteen, discharged in good condition, failed to return later to the clinic, and because of false addresses and often false names, it has been impossible for the Social Service Department to locate them. Thirty-one of the remaining sixty-one have been followed for periods varying from one to eight and a half years. Of the sixty-one patients in this group, all but eight, or 87 per cent, were entirely cured of their original complaints. One patient, whose chief complaint was backache, died some four years later of tabes dorsalis, and a second patient, with backache, was later demonstrated by the X-ray to be suffering with a chronic arthritis of the dorso-lumbar spine. A third patient, with perfect pelvic restoration, but unrelieved of her chief complaint of bladder frequency, proved later to be suffering with renal tuberculosis.

These experiences illustrate the fact that patients with pelvic prolapse need particular study, for the reason that the very evident mechanical displacement may distract attention from other serious disturbances. On nineteen patients, at some subsequent examination, it was possible to demonstrate some degree of recurrence, although many of these patients were relieved of their original complaints. Three patients had decided prolapse of the uterus. The operation for these patients had not been well planned, inasmuch as the uterus, which reprolapsed after an interposition operation, was pathological and should have been removed. The patient was cured by a subsequent vaginal hysterectomy. The interposing of the cervix under the bladder, following subtotal vaginal hysterectomy, was not successful in a second case, and this technic has been given up in the clinic. This patient was cured by suspending the prolapsed cervix by laparotomy.

The third patient was complicated with salpingitis and cystic ovary. An attempt was made to cure her by anterior colporrhaphy and proctopexy with a Gilliam suspension and removal of one ovary and tube. A better plan would have been to have done a panhysterectomy with suspension of the vagina on the round ligaments, together with an overlapping of the fascia under the bladder and proctopexy.

Cystocele recurred with nine patients. This is an entirely preventable occurrence if the pelvic fascia is overlapped under the bladder. We have had no cystocele recurrences since doing this operation the past four years, although in the interposition operation this technic has not been considered necessary.

Rectocele gives the greatest amount of concern in all types of operations for prolapse and is the most frequent type of recurrence. In our series, seventeen, or over 22 per cent, had return of rectocele. The rectoceles recurred following the usual procedure of perineorrhaphy, no matter what particular type of operation was done, but no rectocele has recurred following the more extensive proctopexies. The usual experience is that so much time is consumed in operating on the bladder and uterus that time is not given for a proper and complete operation on the rectum.

CONCLUSIONS.

Prolapse of the uterus can be cured with a very small degree of operative risk if the patients are carefully observed before operation to exclude other causes for cystitis and backache. Prolapse should recur only rarely after operation and cystocele never, provided infection can be avoided. Rectocele is more difficult to cure unless a high dissection of the posterior plane of the pelvic fascia is made and the rectum fixed to a point behind the cervix.

THE 1922 MEETING

All members and guests, who are planning to attend the State meeting in Yosemite, Monday to Thursday, May 15 to 18, 1922, are urged to promptly communicate with Mr. H. H. Hunkins, 637 Pacific Building, San Francisco, regarding transportation and hotel reservations. Mr. Hunkins is chairman of the committee who has this matter in charge, and will give prompt attention and courteous reply to any communications.

Members interested in the program should communicate promptly with the chairman or secretary of the section they are interested in, because the program will be closed during this month. A list of the officers of sections is to be found on page 31 of this number of the JOURNAL.

EXTRAPLEURAL THORACOPLASTY*

By HERBERT A. JOHNSTON, M. D., Anaheim, Cal.
(Johnston-Wickett Clinic, Anaheim, California.)

While the treatment of tuberculosis of the lung will always be the work of the internist, there are certain cases where surgery should be the treatment of choice and from recent developments it appears that this number will be greatly increased in the near future.

Artificial pneumothorax (Forlanini-Murphy) is of great assistance in the treatment of selected types of pulmonary tuberculosis, particularly when the pulmonary and costal pleurae have not become too adherent. Where the adhesions are dense, the pleuræ thickened, attempts at inflation usually fail. In a certain number of such cases surgery of the bony framework of the chest offers definite collapse and immobilization, with a chance of relief or even a cure.

It is well known that absolute rest of a tuberculous focus tends towards its resolution. To prevent mobilization of the diseased lung whose adherent pleurae preclude successful pneumothorax, different methods have been tried. As early as 1908 Friedrich of Munich devised a modification of the Schede operation which he termed "Extrapleural Thoracoplasty." This was done by means of the Schede incision and while successful as to detail, produced considerable shock and was none too well suited to the weakened individuals upon whom it was usually necessary to operate. Sauerbruck, Friedrick's assistant, modified the operation by doing it in two or more stages and under local anaesthesia. The results were better. Wilms of Heidelberg modified the operation still more by using his "columnar resection" anterior and posterior, leaving a central section of each rib to act as more effective compression and better protection to the thoracic viscera. The operation is comparatively simple and in the hands of experienced surgeons consumes but little time and is seldom followed by shock. The immediate risk to the patient is small. The fact that the attachment of the ribs and sternum is cartilagenous provides at once a readily movable and flexible articulation, so that by confining the surgery to the vertebral ends of the ribs, removing large sections which include the angle of each rib, a satisfactory collapse and immobilization of the lung may be procured. It was A. Boiffin, who first clearly demonstrated through J. Gourdet, a pupil, precisely why it is the posterior portion of the rib that must be removed. Gourdet's argument, quoted by Bull, is as follow:

"On account of the yielding rib cartilage the anterior part of a rib can be pressed inwards, while the posterior portion is stiff and, practically speaking, immovably connected with the vertebral column, and in any case can only be moved up and down a little. Further, the posterior part of a rib exhibits a marked concavity forwards, or, in other words, forms an arc the radius of which is much less than that of the arc of the rib otherwise; the angle of the rib forms the most prominent point in this arc behind. Any resection of the ribs which is situated in front of the angle of the scapula leaves behind a stiff unyielding piece of rib, which in accordance with its length will prevent the soft parts from falling in and diminish the costo-vertebral angle. If, on the other hand, we remove the posterior stiff part of the ribs, the anterior part can very easily be turned about the costal cartilage and pressed in towards the thoracic cavity and backwards towards the posterior fragment of rib, so that the entire arc of the rib decreases considerably in its curve and thereby also decreases the volume of the thorax. By this method the anterior part of the ribs is not hindered in its movements by the soft parts, which in other methods stretch over the projecting posterior end of the rib. This principle, as set forth by Boiffin-Gourdet, runs through both Sauerbruck's and Wilms' 'Columnar Resection.'"

The selection of patients upon whom it is best to perform collapse by means of extrapleural thoracoplasty requires particular skill. While in the main one might say that any patient requiring collapse therapy, upon whom the attempt to produce pneumothorax was unsuccessful, would be eligible to chest wall surgery, there are certain limitations. A great deal depends upon the condition of the opposite lung. While it would seem that a slight infection would not materially interfere with the outcome of the operation, the writer is of the opinion that the surgeon should be very cautious in attacking any thorax where the "better" lung shows very evident infection. Roentgenographic studies of all cases should be made. These will reveal the presence of cavitation and give a better idea of the condition of the pleurae, especially its thickness and adhesions.

Case Report

Case No. 7907, referred by Drs. Kalb and Kirschner, Monrovia. Miss A. K., age 31, teacher and native of Nebraska, came to California eight years ago. One sister died at 24 years, of phthisis, otherwise family history is negative. Had usual childhood exanthemata, whooping cough at 15, and bronchitis at 29 with recovery.

Has always enjoyed good health except as above. Very fond of outdoor life and indulged in athletics. Began coughing in February, 1918. Temperature range from 99° to 103°. Became suddenly worse in January, 1919. Change in posture was followed by profuse expectoration and rapid rise in temperature to 105°, with chills. Incomplete pneumothorax by Dr. Kalb repeatedly until December, 1919, resulted in general improvement and reduction of highest temperature from 104° to 102°. Patient kept continuously in bed in a sunny, well ventilated room, near the foothills.

Physical examination revealed a very thin, poorly nourished patient weighing about ninety pounds, having lost twenty-seven pounds in one and one-half years. The heart was regular, rapid (104), no murmurs. The arterial blood pressure was 110/75. The respiratory movements were decreased on right side with increased dullness, harsh bronchial breathing and evident cavitation. The blood contained Hemoglobin 60 per cent, Erythrocytes 3,160,000 and Leucocytes 17,350. Clotting time, 5 minutes. Urine contained a doubtful trace of albumen, occasional pus cells, many crystals calcium oxalate, some epithelial casts, otherwise negative. Roentgenogram of chest showed right lung cloudy

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, San Diego, May, 1921.

throughout with cavities and many pleural adhesions. Left lung clear except for a few calcified glands at hilus.

On June 8, 1920, operation under local anaesthesia, a parasternal incision was made on right side. Extrapleural resection of parts of first to fifth ribs inclusive, closure of muscles and skin. No drainage. Patient made an uneventful recovery, leaving hospital in two weeks. Her general health gradually improved. Sputum decreased and temperature curve improved. Pressure bandage applied.

On September 2, 1920, she was referred back again by Dr. Kalb for the second stage of operation. The roentgenogram showed considerable collapse of the lung but not sufficient to obliterate the cavities. She was not coughing as much and the temperature had been considerably lower since the first stage of the operation. There was practically no respiratory movement of the right chest and no bony union at points of resection. Being quite apprehensive about the operation, a combination of morphine, procain and gas oxygen anaesthesia was used. A paravertebral incision exposing angles of fifth to eleventh ribs being made, sections varying from two to four inches were removed in each instance, always including the angle, without opening the pleural cavity.

She left the hospital in a week and made a good recovery and, excepting a slight infection of lower end of incision and some neuralgia in shoulder, had no post-operative complications.

In a letter dated November 24, 1920, she says: "My temperature is seldom above 99° these days, sometimes normal all day."

Her recovery has progressed satisfactorily up to the present time and the outlook is good.

Summary

1. The extrapleural rig resection under local anaesthesia is a comparatively safe operation.
2. The patient with large cavities and toxic conditions from pus absorption, still has a chance even if artificial pneumothorax has failed.
3. The proper selection of cases for operation is of more importance than anything else and requires careful study.
4. In some instances it is better to divide the operation into more than one stage.
5. Extrapleural resection of the angles of the ribs offers the best means of collapsing the lung.

URINARY PUS CELL COUNT*

By LEON J. ROTH, M. D., F. A. C. S., Los Angeles

Routine laboratory reports concerning pyuria are often fallacious and the interpretations of them frequently lead to wrong opinions, not only from a viewpoint of diagnosis or prognosis, but in segregating cases that either are or are not worthy of serious study.

In the urine the importance of a small amount of pus originating from the glands or mucus membranes of the lower urinary segment or from the genitalia may be nil, yet upon centrifuging such a specimen many corpuscles will be demonstrated that may wrongly stimulate the notion of severe infection. Such interpretations are further induced because the urine submitted for examination has not been properly collected and inspected.

Gross infections are quite apparent and usually the microscopic search for pus cells is negligible, but the finer infections, such as pyelitis, pyelonephritis, obscure prostatitis and vesiculitis, and the remote urinary infections of children and young adults, are problems the course of which becomes more complicated and result of treatment more uncertain without absolute microscopical control of the actual number of white corpuscles.

A characteristic of renal pyuria is that the exhibition of cells is consistent and constant. Urinary pus may be decreased somewhat by rest, and increased by exercise, cold, and alcohol, but with unusual exception, infection once chronically established is continuous and the variation in intensity of this is slight.

A drop of pus in a centrifuged specimen of 100 mils or ten drops in a like volume will, in a pipetted deposit on a slide, show the same number of cells. The microscopic examination of 1 mil or 10 mils of pus in concentration will furnish such crowded fields that they cannot be told apart. The amount of pus produced by a urethral shred collected by pipette from the bottom of a centrifuge tube will, by comparison, show as many cells under a cover glass as a like quantity of pure pus similarly obtained.

Because of the consistent quality of a given specimen of urine 1 c.mm. taken from 10 mils or 100 mils will give the same number of cells.

Until recently we have been counting a definite number of fields and making our estimate on the average number of cells per field in uncentrifuged specimen. This is not a precise method, as cover glass pressure and fluid dispersion cannot be controlled.

Therefore, as a means of more or less accurate diagnostic and prognostic aid, the following method has been adopted. The technique is both rapid and simple, and the count is made without centrifuging.

The fresh specimen of urine is thoroughly shaken and a portion drawn into a red blood cell pipette. This pipette is chosen because it facilitates a final agitation of the fluid. A Thoma Zeiss counting chamber is then filled with the fluid in the method used for counting blood cells. The eyepiece of

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

the microscope is adjusted so that the diameter of the field is eight small squares. One hundred fields are then counted, disregarding the ruling of the counting chamber. The resulting number multiplied by .7957728 will give the number of pus cells in 1 c.mm.

The factor .7957728 is found by the following means:

The field is eight squares in diameter. The radius expressed in mm. is .2 mm. The area of one field is Pi r^2 or 3.1416 x .04 equals .125664. The depth of the chamber is .1 mm.; therefore, the volume of one field counted is .125664 x .1 equals .0125664. If .0125664 equals the volume of 1 field, 100 fields equal 100 x .0125664 or 1.25664. 1.25664 is greater than 1 c.mm., 1 c.mm. divided by 1.25664 equals .7957728 or the factor with which to multiply to obtain the number of cells in 1 c.mm.

The following figures have been chosen, arbitrarily, to designate the degree of pyuria:

0	per c.mm.	No pus cells. 0	Per field 0.
0-100	"	Very few. . . . . 1 plus	" 1.
100-300	"	Few 2	" 2 to 3.
300-500	"	Moderate amount. .3	" 4 to 6.
500-700	"	Many 4	" 6 to 8.
700 plus	"	Loaded 5	" 9 or more.

The variation of specific gravity has no great influence upon computations, but we have adopted 1000 as a standard and the formula expressed as follows:

The known specific gravity is to 1000 as the number of pus cells in 1 c.mm. is to x.

e. g., 1020 : 1000 :: 102 : x.

As a control in the count following prostatic massage the bladder is thoroughly irrigated and finally filled with 100 cc. of mild antiseptic solution. This is voided after massage and the count made using this 100 cc. as a standard quantity. The estimate here, as elsewhere, is relative.

It is desired to convey the suggestion that in making plural counts the physical character and quantity of the urines should be closely similar.

TREATMENT OF GOITRE

By C. L. HOAG, M. D., San Francisco.

When we review the history of goitre, we find that for many years it was regarded as a disease to be treated by medicine alone. It was largely the work of Kocher that made the surgical treatment so successful. Year by year, with increasing experience, and technical skill, surgeons have lowered the mortality rate and have taught the profession, as well as the laity, the need for early operation if irreparable damage is to be avoided. The development of X-ray and Radium therapy has opened up new fields in the treatment of many diseases, and it is not surprising that the goitre problem has received its share of attention. The pendulum has swung from medicine to surgery and now seems to be swinging towards radio-therapy. Much of the treatment is done, unfortunately, in a perfunctory manner, without sufficient thought and care, without proper choice of cases, and without a knowledge of those general principles which are so essential to the intelligent choice of therapeutic methods.

It would seem that a word of warning is particularly needed at this time when this form of treatment is so often carried on by physicians, or even technicians, who have had little or no experience in the treatment of goitre, or even with general radiotherapy.

Our whole system of modern medicine is based upon correct diagnosis. When a diagnosis of thyroid disease has been made only the first step has been taken towards establishing a rational basis for treatment. It is just as necessary to recognize clearly the various forms of thyroid enlargement as it is to distinguish one type of intestinal parasite from another, or to differentiate empyema from pneumonia.

The clinician and the pathologist do not entirely agree upon the classification of goitre, as the pathological picture is not always in accord with the clinical findings. However for practical purposes the following classification meets all requirements.

GOITRE

Atoxic	(1)	Simple hypertrophy, adolescent goitre
	(2)	Colloid, calcified or cystic
	(3)	Simple adenoma
Toxic	(1)	Toxic adenoma
	(2)	Hyperplastic (exophthalmic)
Malignant	(1)	Carcinoma.
	(2)	Sarcoma, etc.

In well developed cases it is usually easy to classify goitre into these groups, but there are many border-line cases giving rise to mild signs and symptoms in which an accurate estimate of the glandular function is essential. It is not only necessary to know that an increased or decreased function exists but also the degree of that changed function. This is often impossible clinically, for a large goitre may actually be deficient in thyroid secretion, while a barely noticeable gland will produce an extreme degree of hyperthyroidism. The thyroid secretion now appears to be the principal regulator governing metabolic processes in the body. By determining

the basal metabolism in goitre patients, an accurate estimate of thyroid activity is secured.

As far back as 1883, Lavoisier made studies in basal metabolism. Many other investigators have contributed to this subject since his time. Briefly, the output of CO_2 bears a direct ratio to the rate of tissue destruction. By measuring the O intake, or the CO_2 output from the lungs over a given time, the rate of tissue destruction is determined. This rate is a constant in all healthy individuals, when taken under standard conditions of food and rest, and corrected for the body weight. It is, therefore, the normal or basal metabolic rate of chemical change within the body cells. While this rate varies very little in health it may be either increased or decreased by disease. With the simplified apparatus now obtainable for this estimation, it is rapidly becoming a valuable adjunct to diagnosis.

A number of diseases influence the metabolic rate, but the changes found in goitre are the most striking of any. In exophthalmic goitre, the rate may actually be doubled—cases of +115 per cent increase having been reported—while in myxedema it may fall to 25-40 per cent below normal. Even allowing for a certain error in the determination, it is more accurate than any clinical estimate and gives a measure of the degree of changed function. It should be used to corroborate clinical findings, not only in toxic conditions but also in large non-toxic goitres where hypothyroidism may be an unlooked for and unrecognized condition. It is invaluable in determining the dose of thyroid extract or thyroxin to be given in myxedema, also in checking up toxic goitres relapsing after operation.

Again, it is valuable in determining the opportune time for operation, or that stage in which the experienced clinician has what Plummer calls a "hunch," that operation will be well borne. At the Crile and Mayo Clinics radical operation is not done in those toxic cases showing a basal metabolism over +50 per cent. Medical treatment, ligation of the superior thyroid arteries and X-ray are used until this point is reached, before removal of the gland is done. However, the time for operation must not be selected upon the basal metabolism alone, as the phase of the disease, from a clinical standpoint, is even more important. All toxic-goitre patients have alternating periods of exacerbation and recession. They do not stand operation well during those periods when the disease is on the increase, even though the metabolic rate is well below +50 per cent.

Simple and adolescent goitre: This form usually comes on in early life, during the period of adolescence. The thyroid is uniformly and moderately enlarged and there is a corresponding increase in all its histological parts. As a rule, it presents few or no symptoms and the metabolic rate is not increased. It is believed by Marine to be an expression of an effort on the part of the thyroid to compensate for a deficient iodin supply in food and water. This form of goitre usually responds to medical treatment with small doses of iodin. Various forms of iodin may be used. One of the simplest and most pleasant is the Syrup of the Iodid of Iron in twenty-minim doses daily, every alternate month. If medical treatment is not successful, X-ray therapy may be tried in addition to the use of iodin, the lack of which is believed to be the cause of the hypertrophy.

Colloid, calcified and cystic goitre: This type of non-toxic goitre may appear at any age. It comes usually late in life, it grows slowly and is often confined to one lobe. When both lobes are involved they are usually unequal in size. Symptoms are from pressure only. The metabolic rate is usually not affected but may be below normal if the normal thyroid tissue is sufficiently destroyed or compressed. The treatment is purely surgical and is called for to relieve pressure and to improve the appearance of the patient. I can not too strongly emphasize that in these cases the X-ray is definitely contra-indicated and if used may destroy the remaining thyroid tissue and bring on hypothyroidism.

Simple and fetal adenomata: These forms are believed to arise from embryonic cell rests. They are usually bilateral, discrete, freely movable masses, multiple in number, varying from the size of a shot to that of a baby's head. They appear at any time in life and grow slowly. Many, later, show toxic signs, others either calcify or degenerate, and become cystic. All tend to compress and replace normal thyroid tissue. Many grow to such size that they produce pressure symptoms upon nerve trunks, the trachea or the oesophagus. The basal metabolism is not changed. The principles of treatment are the same as those for colloid goitre and X-ray is again strongly contra-indicated.

Toxic adenoma: A certain percentage of the simple adenomata become active and produce all the toxic signs and symptoms found in exophthalmic goitre *except the exophthalmos.* These adenomatous masses are usually multiple, circumscribed, vary in size and may affect both lobes. While heart changes, rapid pulse, loss of weight, weakness, diarrhoea and an increased basal metabolism are present, these signs are usually less marked than in hyperplastic goitre. The patient generally states that she has had a goitre for many years, but it occasioned her little trouble until she was about 35. *In contra-distinction to this type, a true hyperplastic goitre, as a rule, gives marked symptoms within one or two years after its appearance.* Any toxic adenoma with a basal metabolism above +10 per cent is producing heart changes and should be treated. Some exhibiting mild toxic symptoms may show an increased basal metabolism only during periods of exacerbation.

X-ray does not affect this type of goitre and is definitely contra-indicated as in simple adenomas. It not only does not alter the adenomas but it damages the remaining norml thyroid tissue which may be barely sufficient in amount to maintain health. It is this change in normal thyroid tissue which is responsible for the apparent though temporary benefit frequently seen after radiation. These masses should be removed surgically, while

taking great care to preserve the normal thyroid tissue surrounding them.

Hyperplastic or exophthalmic goitre: This is the type with which we are all reasonably familiar and more seriously concerned. Exophthalmos, either unilateral or bilateral, with positive von Graefe and Stellwag sign; pulsating goitre mass, either large or small; rapid, irregular heart, often showing signs of hypertrophy and myocarditis; tremor of the hands and tongue; diarrhoea; rapid loss of weight; marked nervousness and change in disposition and a greatly increased basal metabolism are all signs which make diagnosis easy. *In contra-indication to the toxic adenoma these goitres develop within one to two years and the signs and symptoms are often recognized before the thyroid enlargement is noticeable.*

Even when these classical signs are not sufficiently well developed to warrant a diagnosis of hyperthyroidism, the basal metabolism is already well above normal and furnishes the first reliable proof that the disease is present.

The pathological picture shows the acini, normally tubules, lined with a single layer of cells, now packed with newly formed epithelial elements, all active in secretion.

Fortunately, it is upon this type of growth that X-ray and Radium has its most effective action. As in Cancer, these newly formed cells, resembling the embryonic types, are most affected by radiation. Here, Roentgenotherapy may be of the greatest value, and if not curative, very helpful in decreasing the amount of thyroid secretions and the signs and symptoms of toxicity. In some cases, radiation is apparently curative, in others the effect is temporary and this treatment must be followed by a bilateral resection of the gland, with or without previous ligation of the superior thyroid arteries.

The milder forms of treatment are especially useful in preparing the patient for operation when the metabolic rate is above +50 per cent.

Hyperthyroidism is a rapidly progressive disease. Permanent heart damage keeps pace with its advance. While conservative treatment should be given a fair trial, the tendency to procrastinate and dilly-dally along with these toxic goitres can not be condemned too strongly. Treatment must not only be beneficial but positively curative, reducing and keeping the metabolic rate well below +20 per cent. Above this point, heart damage is still going on, even though the patient is much improved.

The use of Roentgenotherapy should be controlled by frequent determinations of the metabolic rate and quickly followed by resection if continued and rapid improvement does not occur.

Malignant growth—Carcinoma, sarcoma, etc.: These conditions are relatively rare but are not infrequently seen. The diagnosis is based upon the same principles here as it is elsewhere in the body, namely, steady growth with fixation to the surrounding tissues. Naturally these tumors must be removed carefully and after that the area should be well treated with X-ray or radium.

SUMMARY

(1) It is necessary to determine accurately the type of goitre before rational treatment can be given. The basal metabolic rate is an important aid in corroborating the clinical findings.

(2) X-ray or Radium therapy is indicated in simple hyperplasia and hyperplastic goitres only. It is contra-indicated in colloid, cystic, nodular and adenomatous types.

(3) While the treatment of goitre is essentially surgical, medical treatment, Roentgenotherapy and radiotherapy are sometimes curative and are often helpful in decreasing thyroid activity and in preparing the patient for operation.

177 Post Street.

A LABORATORY AND CLINICAL STUDY OF THE BACTERICIDAL ACTION OF SOLUTIONS OF RADIUM EMANATION

By JOHN ALBERT MARSHALL, D. D. S., Ph. D.,
San Francisco.

From the Radium Laboratories of the University of California Hospital; the Research Laboratories of the George Williams Hooper Foundation for Medical Research and of the College of Dentistry, University of California, San Francisco.

Recent observations upon the use of radium emanation indicate that there is a possibility of employing this substance in the treatment of chronic dental abscesses. Until further laboratory data can be obtained, it appears advisable to mention briefly the results thus far recorded, with the hope that other workers in this field may be sufficiently interested to verify some of the conclusions.

The bactericidal action of radium has been studied particularly by Lequeux and Chrome,[1] and Iridell and Minett.[2] In their experiments they exposed different organisms to radium emanation for varying periods of time with a noticeable inhibitory effect upon the growth of cultures of streptococcus. Although the author has not repeated the experiments referred to above, his clinical findings are in apparent accord with the deductions offered. Bacteriological examinations of the treated canals indicated sterility in 85 per cent of the cases. In fact, the summary presented points to the possibility of a new application of radium in the treatment of certain diseased conditions.

The apparent success which has attended the radium therapy of skin lesions suggested the advisability of developing a modification of the present method of application which would make possible the study of the effects produced by this agent on chronic dental apical abscesses. A summary of nearly a year's observation of clinical cases shows that lesions of this type yield readily to the new therapy, and that up to the present time no untoward effects of the radium treatment have been observed.

Through the courtesy of Dr. Howard Morrow, Dr. Laurence Taussig, and Mr. L. B. Clark, it has been possible for the author to secure capillary tubes containing radium emanation. These tubes had been used in the skin clinic and eye clinic for various purposes until the "de-emanation" had

proceeded to such an extent that further application for this work was purposeless. Although the degree of radiation is recorded in the tables in terms of millicuries, the measurement of the Beta radiation from radium *D* and *E* has not been made.

Radium emanation or Niton is a gas, the disintegration products of which are solids. It is a solution of the solids which is being employed. That this solution contains alpha, beta and gamma rays is known, but the effect upon diseased tissue is perhaps due to the predominance of the beta radiation coming from radium *D* and *E*. It may be recalled that Tarnowsky[3] quotes Hektoen to the effect that radium "emanation" inhibits phagocytosis and, hence, lowers the natural resistance of the affected part; but in these experiments I have employed, as already stated, a preponderance of the soft beta rays.

METHOD OF PROCEDURE

A small amount of Ringer's solution may be rendered radio-active by crushing in it a capillary tube containing a known quantity of radium emanation. This operation is conveniently accomplished by placing the tubes in a sterilized mortar of about 20 cc capacity, covering the tubes with Ringer's solution and then crushing them. The preparation is transferred to a suitable container and carried to the operating-room. On account of the rapidity with which the radio-activity of this solution diminishes, it was found advisable in this research to crush the tubes at the exact time at which the experiment was performed, but no more than an hour was permitted to elapse between the preparation of the solution and its application in the clinic or laboratory.

The radio-active liquid was carried to the root canals of the tooth by means of J. & J. sterilized cotton points. These were sealed in the canals for a period of from one to four days. Subsequently the treatment was removed, the pulp canals tested for sterility, and finally filled. With one possible exception, there has been no evidence of succeeding soreness or pain. The exception referred to is one in which the pericementitis resulted more probably from mechanical trauma incident to the previous curetting of the canal than to the action of the radium itself. The amount of solution carried to the tooth averaged 0.05 cc.; in this there was approximately 0.0630 millicuries of radium emanation. The variation in the dosage is noted in the appended table.

Table I

Millicuries of tubes *	Millicuries per cc. of solution	Amount placed in tooth
6.0	1.20 per cc.	.060 millicuries
7.9	1.58 " "	.079 "
5.5	1.10 " "	.055 "
4.6	0.92 " "	.046 "
9.1	1.82 " "	.091 "
7.5	1.50 " "	.075 "
6.3	1.26 " "	.063 "
5.3	1.06 " "	.053 "
13.8	2.76 " "	.138 "

* Not freshly prepared. These values were computed from tubes which originally contained a radio-activity varying from 50 to 100 millicuries.

Table II

Summary of Twenty-seven Cases

Clinical condition	Treatment	Results
Chronic apical abscess.	Radium applied four days.	Canals filled. No unfavorable symptoms after ten months.
Infected pulp with acute pericementitis.	Radium applied seven days.	Pericementitis very severe. Tooth extracted.
Chronic apical abscess of long standing.	Radium applied seven days, removed. Second treatment given.	Canals filled and no unfavorable symptoms after ten months.
Acute abscess.	Two treatments of radium of three days each.	Canals filled. No unfavorable symptoms after six months.
Chronic apical abscess.	Two treatments of radium of three days each.	Canals filled. No unfavorable symptoms after six months.

THE MISSING LINK IN OUR OPERATIVE TECHNIQUE

By P. CAMPICHE, M. D., San Francisco

For several years I have intended to call the attention of the surgeons of the West to a weak point in the work of our operating-rooms, namely: the lack of nurses properly trained to assist at major operations.

The prevailing system consists in having the pupil nurses spend, in the operating-rooms, three or four months of their training, during which time they assist as best they can at all major and minor operations. The whole thing has been arranged with the sole idea of suiting the nurses three years' course, and while the system is eminently advantageous to the pupil nurse, I claim that it is unfair to the patient and has no regard for the convenience of the surgeon.

I recognize that most pupil nurses do their best, are willing workers, eager to learn, and are quite in earnest about their duties; but alas, they are sadly lacking in experience, and good will cannot make up for that! Time and again it happens to me, after embarking on a serious abdominal operation, to discover that the nurse present had never seen a laparotomy before. When I remark to her that something is not correct, she tells me quite frankly, "How could I know this? I never saw a laparotomy in my life!" Such admissions used to disturb me greatly and I was often in fear that something serious would happen; but I tried to make the best of the situation and, after much explaining and much waiting and sending for instruments that have been forgotten and changing sutures that had the wrong size, etc., etc., I manage to finish in two hours an operation that should not last more than one.

I would not say that the nurse's inexperience has been directly injurious to anyone in any case that I know of, but I contend that these delays unnecessarily prolong the anesthesia and operative shock and are directly detrimental to the patient. It is the unnecessary loss of time and the clumsy technique that are objectionable.

I am not a friend of those who operate by the clock and who try to make surgery a sport, and come and tell me that they have removed an appendix in six minutes while the previous record was six and a half minutes. But all the same, I find that in many cases with no special difficulty our operations are entirely too slow. About one-third of the time is consumed in sending for this and boiling that and trying needles, etc., etc. The days of pioneer surgery are past. Most operations have now become routine work and perfectly regulated affairs, with little place for unexpected developments and unforeseen complications. Therefore, there is no reason why the assisting nurse should not be well acquainted beforehand with all the details of this work.

Then a word about the surgeon's peace of mind. The feeling of insecurity, the necessity of constantly watching, of checking up the sutures and the needles and all the instruments that are passed to him, is an unnecessary hardship and a strain on his mind, when it should be left entirely clear and free to grapple with the difficulties of the case.

At the time that I was being trained as a young surgeon, the sister assisting at all major operations had filled that position for seventeen years, and I understand that they have kept her there ever since! She would put into our hand the right instrument or needle at the right minute, and this without having been asked for it, and without a word being spoken. She taught me how to do a gastroenterostomy and an intestinal resection, and I am not ashamed to admit it. I once heard the chief, who was in a happy mood that day, tell her, "Sister, some day I will let you do a gastroenterostomy."

All the surgeons in Europe and, I believe, also in the East have in their hospitals one or two of these trusted nurses to help them in their operative work. In fact, many men known for their brilliant technique owe much of their success to the admirable co-operation rendered by these clever nurse-assistants, and they would not think of doing anything worth while with a beginner, lest this would injure their reputation!

Why should it be impossible for the hospitals to make the necessary change in their staff? Each operating-room of consequence should have one or two graduate nurses under a two or three year contract, engaged especially to assist at all major operations and serious cases. The head sister or the head nurse would be the one to decide which are the cases requiring the presence of this experienced nurse, so as to make sure that such valuable assistance would not be wasted on small things. These positions could be given as a sort of reward to nurses who have shown a special aptitude for that work during their training, and who possibly would be willing to take a post-graduate course of a few months in this particular branch before taking up their new duty. It seems to me that this would be a fine field for a bright and intelligent woman anxious to engage in some responsible and eminently useful occupation.

For all that, the education of the student nurses would not have to be neglected; on the contrary, they would first act as aids to the first nurse and would have a chance to see a few major operations without bearing, themselves, the responsibility as they often do now; then later they could be left alone. I fully realize that we surgeons have a clear duty to contribute to the instruction of the pupil nurses, but I maintain that this should be done in simple cases first, in order to avoid any disturbance, and not in difficult or even critical interventions, as it now often happens. Then the rights of the patient have to be safeguarded, too. Most hopsitals make a good charge for the use of the operating-room, and for this the patient is supposed to be entitled to the best attention in every respect; and he is not getting it now, if he has to stay two hours on the table for an operation that with proper assistance could easily be finished in an hour.

I have talked to some of my friends about this matter and I am convinced that there is a demand right now for competent nurses to assist at major operations. I am certain that surgeons would

patronize the hospitals offering them such additional facility. Personally I would send my work there, regardless of previous affiliations, first, for the sake of the patient whose interest is paramount in this matter, and second, for the sake of our surgical technique, which ought to tend more and more towards perfection in every particular.

IMPROVEMENT FOLLOWING TONSILLECTOMY CLINICALLY EXPRESSED *

By HENRY H. LISSNER, M. D., Los Angeles.

In taking up the end result of tonsillectomy and its relation to the clinical manifestation of pre-existing disease in the short time allotted me to discuss this subject, it will only be possible to touch some of the more important points. The subject is a particularly far-reaching one, and I will briefly give my impressions of some of the most important clinical manifestations of absorption from the tonsils in relation to certain entities which have impressed me most.

The upper air-passages and the influence of infected tonsils upon the upper respiratory tract has been excluded from my discussion. If we then start with the neck, we have to deal with the influence of tonsillar infection upon the thyroid. It is a well-established fact that certain forms of toxemia or pus absorption, particularly from the tonsils, have a definite influence on the thyroid. This is evidently manifest in two types of cases; first, the adolescent or pre-adolescent type of thyroid, which is physiological in character up to a certain point, and the adult type which is pathological. Those who have had experience with the former type must have been impressed by the fact that following tonsillectomy the active thyroid symptoms are greatly diminished. That certain types of nervousness, headaches, change in temperament and disposition, which could be attributed to active thyroid, are immensely improved. In the adult type the tonsil plays as important a role from the standpoint of thyroid irritability as other focci of infection. Naturally, one must eliminate and search for other sources of possible thyroid irritation before considering the tonsils the sole source of infection. One case, in particular, illustrates this point:

A young woman with a vascular goitre, with marked thyroid activity and enlarged tonsils, had her tonsils removed. About four weeks after the tonsillectomy she developed an acute appendix, which was also removed, a ligation of the superior thyroid vessels was done at two sittings, following which the thyroid was removed. This young woman made a perfect recovery, and while she had been invalided for about two years, six months after the thyroidectomy she returned to her work with a normal pulse and with a decided improvement in her general condition.

That infected tonsils do have an influence on the production of thyroid symptoms and irritation, and that following tonsillectomy a definite amelioration of symptoms must be conceded, so that in dealing with thyroid disease of either adolescent or adult life, the role of the tonsil in its relation to the production or the increase of the symptoms due to definite thyroid disease must be considered.

With regard to the cervical adenopathies, and the definite types of painful glands, and the secondary enlargement of the bronchial glands, there is a definite improvement shown following tonsillectomy. The pain in the lymphnodes in the neck is due primarily to tonsillar infection, and that this form of irritation or infection does extend to the bronchial glands must be conceded.

This brings us to the bronchial manifestation of respiratory infection secondary to the tonsils. The forms of dry, hacking couch persistent with or without attacks of tracheitis or true bronchitis are frequently met with as the result of chronically inflamed tonsils. The degree of bronchial irritation depends upon the amount of absorption from the tonsils, and it is in direct proportion to the activity of the tonsillar infection whether it is an active tonsillitis or an acute exacerbation of chronic tonsillitis. Acute tonsillitis, per se, is not as frequently responsible for bronchial irritation as is the chronic variety, particularly that form of chronic tonsillar absorption which, by throat examination, shows a few enlarged tonsillar crypts and some scar tissue in the tonsils. Such tonsils appear harmless, but in cases of recurrent attacks of bronchitis, or, as the patient expresses it, "catching cold all the time," the removal of such tonsils is usually followed by a clearing up of the bronchial condition and a diminution in the size of the cervical and bronchial glands, when not complicated by tuberculosis.

In certain forms of heart disease the influence can be directly shown; not only is this true in children, but also in adult life. Types of irritable heart, tachycardia, definite arrythmia and myocardial changes are improved by the removal of the diseased tonsils. Where the myocardium alone is involved the improvement is much more pronounced than where the valves have been attacked. Endocarditis and pericarditis do follow as complications of acute tonsillitis, and where a diseased tonsil is removed in the interim following such an attack, the improvement of the heart is very much slower, and the permanent damage is less likely to disappear than when the heart muscle alone is involved. There seems to be a greater ability toward the heart muscle regeneration with less permanent damage resulting than where the endocardium or pericardium is affected.

In the gastro-intestinal tract the symptoms of nausea, vomiting, toxic diarrhœa and pain are usually much improved following tonsillectomy. However, where there is a focus of secondary infection, such as ulcer of the stomach or appendicitis, these conditions do not materially alter in character, but run the usual course independent of tonsillectomy. Naturally, there are a great many symptoms referable to the gastro-intestinal tract, such as pain, belching, so-called indigestion, eructations of food, hyperperistalsis, etc., for which the diseased tonsil has been held responsible, and

* Read before the Ear, Nose and Throat Section of the County Medical Society.

which very frequently remain after tonsillectomy, but in these cases they are still persistent from another source of irritation. In other words, the result of tonsillectomy and its influence on certain conditions of the gastro-intestinal tract is not as brilliant as it is in some other fields.

This same observation, I think, holds true for infections of the gall-bladder, as an infection once established from whatever cause in the gall-bladder, must be treated as a definite disease of that organ independent of its primary source. In gall-bladder infection there is a particularly definite etiology and it is often difficult to ascribe it to a direct tonsillar infection. The etiological factors are so numerous that it can only be ascertained by careful and painstaking investigation, both clinically and laboratory, as to whether or not the tonsils were the primary path of the infection.

Probably the most brilliant effect of tonsillectomy is seen in certain types of joint disease. One need only mention the acute arthritides, the most pronounced example of which is acute articular rheumatism, to note the influence of tonsillectomy on this particular condition. I would make this distinction, however, and tend mostly toward the general classification of arthritis, of which acute articular rheumatism is a form, and take up secondarily the other types of chronic arthritis as definite diseases of so-called arthritic nature.

Various theories are advanced and much discussion has been had in medical literature as to the etiology of certain forms of chronic arthritis. There are, however, definite cases in which the etiology can be directly traced to the tonsil. I have several of such cases in mind where cultures made from the tonsils have shown the same type of organism as was recovered from the joints of acute, septic arthritic cases which were not of the type of acute inflammatory rheumatism. Such cases following tonsillectomy show a decided tendency to improvement, and in that type of case, as compared to the rheumatic type, there remains behind definite joint changes which do not occur in acute inflammatory rheumatism. This type of arthritis even after tonsillectomy also shows a tendency to remissions, not perhaps as frequently as they would before, but they do occasionally light up in isolated joints which have been previously affected. In acute articular rheumatism, when the acute inflammation has subsided, there is no residue of joint involvement, and if the individual has escaped the heart complication of the disease, the tendency to recurrence is reduced to a minimum.

In certain forms of acute nephritis there are times when the condition can be directly traced to tonsillar infection. This is when a hemorrhagic nephritis follows an acute tonsilitis. In this type of infection the damage to the kidney is of a more permanent nature than is met with in the ordinary and more frequent form which is shown by albumen, a few casts, backache, and other milder symptoms. This type of toxic nephritis clears without leaving any permanent damage to the kidneys after tonsillectomy. Cases of multiple abscess of the kidneys naturally run a more chronic course, and leave in their wake permanent kidney disease. It must be remembered that not infrequently then the kidneys show the effect of tonsillar absorption, and the nature and permanency of the damage depends on the nature of the involvement of the kidney tissues.

In no form of disease, so far as the effect of tonsillectomy upon it is concerned, is the result as striking as it is in those forms of acidosis of toxic, rather than diabetic origin. I am firmly of the opinion that acidosis, particularly in children, is very much more frequent as the result of tonsillar absorption than we ordinarily think. This condition is met with in young children, and the cause of the illness of the child is usually put down as dietary indiscretion, or an acute intestinal upset. It starts with heaviness and drowsiness, and sometimes goes into a mild coma or delirium with fever, nausea, vomiting, headache and a general lassitude. The children are fretful when disturbed for examination, peevish and hard to manage. The general physical examination is negative. Such attacks occur at intervals. The child is usually given a physic, the diet cut down, the fever causes it to drink an abundance of water, and in three or four days the child recovers. An examination of the throat of these children will show tonsils not as frequently acutely inflammed as with subacute and chronic inflammation. The tonsils are sometimes large with prominent crypts which may or may not be blocked; sometimes rudimentary in character and buried, but still showing the evidence of chronic inflammation. The urine shows acetone and diacetic acid, but the blood sugar is usually within normal limits. Tonsillectomy in such cases works an absolute cure. In fact the result in this type of case is almost spectacular. These children pick up, grow, gain in weight, become lively and normal in every particular.

There still remains to be discussed the influence of the chronic tonsils on the so-called neuralgias, neuritis, headaches and other indefinite types of nervous manifestations which are attributable to infection. These conditions respond very quickly to tonsillectomy. Such cases are recognized by severe headaches, either unilateral or bilateral: if unilateral assuming the type of supraorbical neuralgia, if bilateral being expressed by severe pain, fullness, pressure over the frontal or parietal regions accompanied by severe nervous manifestations such as irritability, sometimes a definite mania as was witnessed in a case observed by Dr. Montgomery and myself, sometimes accompanied by nausea and vomiting with head pain, fleeting joint symptoms, palpitation, and an irregular heart. These cases usually materially improve without recurrence following tonsillectomy.

Just a word in conclusion about cultures in the bacteriological studies of the tonsils. A great deal of information can be obtained by tonsil cultures in those cases where the tonsils are manifestly inflammed or show evidences of acute or subacute inflammation. A culture taken from the tonsillar crypts rather than from the surface

of the tonsil will not infrequently show hemolytic streptococcus and staphylococcus, or some other type of organism which would be of sufficient virulence to cause absorption and still not produce acute local evidence of its presence. It would seem to me worth while to culture innocent looking tonsils to determine whether or not they may be harboring such a germ.

TIC DOULOUREUX *

By HOWARD C. NAFFZIGER, M. D., 291 Geary Street, San Francisco, Cal.

In the treatment of a series of cases of tic douloureux in the neuro-surgical service at the University of California Hospital, it has become evident that certain misconceptions regarding this disease and its treatment are prevalent.

Operations upon the gasserian ganglion are, in the minds of the profession, highly dangerous procedures followed by great deformities. Of all the major operations in surgery there are few, if any, which carry a lower mortality than the radical operation for the cure of tic douloureux. The risk to the patient is not to be compared to the risk assumed in operation upon the gall bladder and stomach. The mortality in radical operations for tic douloureux is reported from many of our leading clinics. In the Johns Hopkins Hospital service, the Peter Bent Brigham service at Boston, the University of Pennsylvania Hospital service, the Mayo Clinic and the University of California Hospital service in 1920, over 150 operations have been done, with but one death, and this from a cause not directly connected with the operation. Cushing has reported over 300 consecutive cases without fatality.

The results obtained from the operation are generally quite satisfactory. Careful preoperative diagnosis is the first essential, and the Gasserian operation should be limited to appropriate cases. If the operation is performed for all types of intractable pain over the face, the results will be far from satisfactory. In making a diagnosis of tic douloureux the character of the pain is the deciding factor.

What, then, is the character of the pain? It is sharp, jabbing and lightning-like. It occurs in short paroxysms, and then stops completely. There is no continuous pain. The recurrence of the paroxysms may vary from a minute to hours, but between paroxysms there is complete relief.

The pains are characteristic of true tic douloureux. While other features of the disease may need a word, the characteristic pain is the determining factor in diagnosis, and if radical operations are confined to those who have it in great severity, the results will be gratifying.

The cause of this disease is not yet fully determined. Ascending neuritis and chronic inflammation of the Gasserian ganglion have most supporters. In the literature the average ages of onset given is between forty and fifty years. It rarely appears before thirty years, and in our series the average age has been sixty-two years. The cases are about equally divided between the sexes. The right side of the face is more frequently involved than the left. Bi-lateral involvement, while not rare, is infrequent. It is exceedingly rare for the ophthalmic division to be first involved. The favorite sites are in the infra-orbital or inferior dental nerves. No authentic cases of tic douloureux have been cured by removal of teeth or treatment of sinus diseases. In tic, trigger points are common. The slightest touch or movement of these areas initiate an attack. These areas are often about the angle of the mouth or also of the nose. In certain patients the pain may be limited to the division of the nerve primarily affected. More frequently it spreads to other branches.

The paroxysms of pain recur at varying intervals from less than a minute to a part of a day or several days. Complete remissions of months, or occasionally years, are not uncommon.

Pain is always severe. A recent case in our clinic was that of a man, seventy years of age. He was found lying on the steps of the hospital with his few belongings in a burlap sack. His beard had been unshaven for weeks, face unwashed, hair matted together, and body emaciated from long inability to take food. He was unable to speak, eat, or touch his face. The fear of the approach of anyone, of a touch or a draught of air, and his terror-stricken appearance made one wonder how he had escaped morphine addiction or self-destruction, to which these patients often turn for relief.

For pains occurring over the face in the distribution of the fifth nerve true tic forms one group. In this we have classified those cases having pain of the type described above. Cushing has divided these into major and minor neuralgias. The etiology is as yet obscure, and since in essential points the disease is the same and varying only in degree of severity, we have preferred to group them as mild cases and severe cases, and on this basis to vary our treatment.

The radical operation is indicated only on the severe cases. Removal of the Gasserian ganglion has, of recent years, entirely given way to the simpler and less dangerous procedure of severing or avulsing the sensory root. Permanent loss of function of this cranial nerve is a small price to pay for relief in extreme cases. In those of less severity the disturbance caused by the loss must be weighed against the degree of pain the patient is having, and the possibility of satisfactory relief by a simpler surgical procedure. This decision must be made by the surgeon. To each patient, the pain of his particular tic is most severe. He is unable to foretell how much the feeling of numbness or stiffness, which follows section of the sensory root, will disturb him. The surgeon must judge, bearing in mind the severity of the pain, its character, and the temperament of the patient. Paresthesiaes following the radical operation are not uncommon and with fear of pain forgotten, the patient may eventually come to believe that the pain was less troublesome than these odd sub-

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

jective feelings. With such considerations in mind judgment is often difficult.

While the operative risk is small, an operation which leaves the patient with unpleasant paresthesia is not a satisfactory one. When there is any question in the surgeon's mind as to whether he is dealing with true tic or some other type of pain, radical operation should be deferred and some measure adopted which is not permanently destructive to the nerve. Of these procedures alcohol injections of the nerve trunks and neurectomies may be considered. Of the nerve fixatures used, alcohol has been generally adopted, and has completely superseded the use of such agents as osmic acid. Both alcohol injections and neurectomies give but temporary relief. The injections are limited in their use to the second and third divisions of the nerve. When successful they give entirely satisfactory relief for a variable period—usually a few months to a year. There are definite risks associated with their use, and apart from the risks there are other disadvantages. The best that can be said for them is that when successful they give temporary relief and offer a clinical test of the results from blocking of the nerve. The disadvantages are, the injection is a painful performance. It is customarily done without general anesthesia, in order that the pain experienced may give indication when the nerve is pierced.

Serious complications are too common. Even in experienced hands the injections are often unsuccessful. In inexperienced hands, injections are not only more frequently unsuccessful, but complications are common. At the University Hospital one patient has come for treatment, having lost an eye as the result of alcohol injections. Corneal ulcers are common. Sloughing of the middle ear, persistent tinnitus and dizziness have been seen. A recent case with a mild tic has come to us with persistent diplopia, following an attempt to inject the first division. For such reasons it is our feeling that alcohol injections are to be considered in themselves major procedures. They have their place in surgical therapy, but are not to be undertaken inadvisedly.

Regarding injections of the Gasserian ganglion itself, this measure may be dismissed on the ground that the risk of it is greater than section of the sensory root of the ganglion.

Most surgeons favor the alcoholic injections of the second and third main divisions of the fifth nerve rather than neurectomies, on the ground that all the branches of these divisions are in this way blocked and no scar remains.

Peripheral neurectomies are, of course, not to be done except when the pain is entirely limited to an accessible branch. In such they have certain advantages, and have seemed to us to be the treatment of choice. It is recognized, of course, that the relief is temporary, but this is also true of the injections. It offers the same clinical test as to whether relief is obtained or not. Although temporary in effect, it may be all that is necessary in the very old and feeble. As to the scar, this has no significance, and if the operation is properly performed will be barely visible.

The advantages are that an anesthetic may be used. The operation is a minor one, and there is no question of locating the nerve as in blind punctures. The relief obtained is certain; it averages longer than after injections, and without the same dangers. When one is dealing with one of the severe cases of tic there can be little justification in postponing the radical operation and subjecting the patient to repeated painful temporary measures. The mortality of the operation for permanent relief is certainly not greater than one or two per cent in experienced hands.

The complications of the operation deserve comment. The idea seems widely dissemminated that marked deformity of the face, hideous scars and facial paralysis follow the operation.

One of the complications of the operation is a peripheral facial paralysis. It is not, however, of frequent occurrence. There seems to be two types, one in which weakness of the facial muscles on the operated side appears on the second or third day after operation; gradually increases until it is complete or nearly so. It gradually clears, and the muscles are back to normal in about three weeks.

There is a second type of peripheral facial palsy occurring on the same side, which may be evident at the conclusion of the operation. We have had one of these in our series. It appeared at once after an avulsion of the sensory root. It was complete and remained so for six months, since which time it has gradually but steadily improved. The recovery to date is perhaps 50 per cent. We have had no permanent facial palsies. The reason for the appearance of them is not known; the operation is, of course, not near the facial nerve; the skin incision is well above it, and the intracranial work is in the middle fossa. Stripping of the dura from the petrous bone followed by hemorrhage about the seventh nerve, and hemorrhage into the canal carrying the nerve have been suggested as causes. Adson advanced the idea that damage within the pons following the avulsion of the fifth root is accountable. Against this is the fact that facial palsies occur also after section of the root without avulsion. The cause of the palsy is as yet unsettled. Fortunately it occurs infrequently. Other complications are corneal ulcers followed by opacities.

During the year 1920, on the division of Brain Surgery at the University of California Hospital, ten cases have had operations on the Gasserian ganglion for the relief of tic douloureux. There have been no deaths. The average age in this series is sixty-two years. We have had one complete peripheral facial palsy follow operation. Return of function in the paralyzed muscles began in six months and is continuing. In the same case there was a corneal ulcer, now healed, which has left a considerable opacity, but still permits of a useful amount of vision in the eye.

One other case had a small corneal abrasion which healed without any opacity.

Corneal ulcers are usual in cases having facial palsy. The lack of sensation in the eye renders slight injuries or irritation inappreciable to the patient, and the dryness of the cornea permits par-

ticles to adhere. If these are combined with inability of the lids to close, injury is unavoidable. The danger of corneal complications seems to decrease after the first few weeks. Another postoperative complication is hemorrhage into the middle ear. This is likewise uncommon. Accurate figures are not available, because it is rarely mentioned in the literature and is not generally appreciated.

Unilateral paralysis of the muscles of mastication was formerly the rule. At present it is possible frequently to spare the motor root.

SUMMARY

All cases of intractable pain over the face are not tic douloureux.

This diagnosis should be confined to those having heavy paroxysms of the type described, but without any continuous pain.

Temporary relief and diagnostic information may be obtained from alcohol injections and neurectomies. The latter have a valuable place in treatment. For permanent relief the radical operation of severing the sensory root is the preferable procedure. It involves but slight risk either on the score of mortality or complications.

PLASTIC SURGERY IN AND ABOUT THE EYELIDS *

By RAYMOND J. NUTTING, B. S., M. D., Oakland, Cal.

Plastic surgery in and about the eyelids finds its chief indication in the relief of those deformities due to the contraction of cicatrices from burns; deformities resulting from defective congenital development; loss of parts resulting from injury, which has been especially brought to our attention on account of the late war; removal of malignant growths; the destructive ulceration from other general diseases; or loss of function of the lids from lesions of the third or seventh nerves.

One should have a thorough knowledge of the surgical anatomy and histology of the lids and surrounding parts before doing plastic work in this region, so I shall not take any of your time by describing same.

A guarded prognosis should be given in most plastic work about the eyelids, and it is of the utmost importance that a good photograph be taken before and after each operation, in order to avoid undue criticism by the patient, or his friends. There is no question of the value of such photographs for the physician's records and for future reference.

In general, whatever method one uses, whether it be pedunculated flaps, grafts of different types, the epithelial inlay or outlay, it is very important that great care be used in obtaining facial symmetry—symmetry of features, on the one hand, and symmetry of movement, on the other. Great care must be taken also in the minor details, such as accurate approximation of skin edges; on the even application of grafts in a state of normal skin tension; and, in most cases, a gentle pressure should be evenly maintained to prevent the collection of any exudates, and insure the proper nourishment of the grafts. Lastly, *asepsis* and a properly prepared field, and not too much speed are important points in the operation.

There are broad general rules governing repair of cicatricial tissues, whether it be of a distorted lid or a contracted socket. Every such condition presents problems peculiar to itself, requiring independent study and treatment, so it is very difficult to give all these methods of treatment in a paper at this time. Some operators prefer a Wolfe graft; others, pedicle flaps; and others, Thiersch transplants, whether epithelial inlays or outlays in certain cases, or simple grafts as the case may present itself.

An operator is naturally in favor of that operation from which he has obtained the most satisfactory results, but possibly in selected cases just as good a result can be obtained from one method as from another.

There are some conditions which are especially adapted to the epithelial inlay or outlay, such as extensive burns about the lids, face and forehead, resulting in extensive cicatrices which would make a pedicle flap impossible. Great progress was made in this work during the late war, by Esser, Gillies, Waldron, Risdon and others, who have all done great work in plastic surgery about the face. As it will be impossible to take up buried skin grafts for correction of obliterated cul-de-sacs and orbit in the time permitted, I will limit my remarks to pedunculated flaps and simple Thiersch autodermic grafts.

The replacement or readjustment of tissues by fashioning and mobilizing flaps of adjoining skin should be chosen whenever possible, and is especially useful in restoration of the lower lid.

The pedunculated flap has its greatest usefulness in restoration of the lids or canthi, especially where there has been great loss of tissue. It is also used where the nutrition is poor, which, of course, would be fatal for a skin graft. The advantage of pedicle flaps lies in their good vitality, which has the effect of making them more resistant to infection; and, secondly, these flaps do not shrink with time. Their only disadvantage is that they leave a linear scar, but this, it is true, becomes less conspicuous as time goes on, and, if proper care is taken these scars eventually can be scarcely seen. It is also very important that the base be not too narrow and not more incisions than are absolutely necessary be made. The skin edges should be very carefully coaptated, strict asepsis carried out, and all hemorrhage stopped. The wound should be dressed with a dusting powder, such as aristol, covered with perforated rubber tissue or dental wax, and an even pressure-bandage applied.

The Thiersch method, on account of its simplicity, is the method of choice about the lids. Thiersch grafts are most successful when support is not needed, particularly in the upper lid, but we have all seen good results from grafts in the lower lids in special cases.

The grafts are usually taken from the arm or inner side of the thigh, where very few hairs are found and the skin very thin like that of the lids. The part to be excised is shaved and scrubbed

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

carefully with soap and water, sponged with ether and alcohol, followed by bichloride solution, excess washed off with salt solution and the area covered with sterile gauze-dressing moistened with normal salt.

In cutting the graft, the knife and skin area should be coated with sterile vaseline and the excess wiped off. This step eliminates the tendency of the skin to move with the knife. Dr. Walter Parker, has been using this method for years, and the use of vaseline has not been found to interfere with the healing process.

The surface to be grafted requires very careful preparation. Hemorrhage should be entirely controlled, and the surface allowed to glaze over. The graft retains its vitality so long that the length of time between the cutting and application need not be considered. When the graft is once in place it should be disturbed as little as possible. The graft should cover the entire surface, as well as slightly overlap the skin margins, or any possible contiguous grafts. There should be no tension in any direction.

The most important point in all skin grafting is overcorrection, and this should always be done. In repairing the skin of either the upper or lower lid, after the wound has been properly prepared, the lower lid should be drawn up over the upper, or vice versa, as the case may be, far enough to smooth out the grafted area and fastened by sutures passed through the lid margin so that they will not interfere with the wound. They also should be fastened above in the forehead or below, as the case may be, to hold the lid in place.

METHOD OF DRESSINGS

1. In advantageous surroundings and for small grafted areas the open-air treatment has the advantages of lessened tendency for the graft to become displaced by the dressings. After the graft has been placed in position, aristol is dusted over the edges, and no dressings applied other than for protection. Rolls of gauze are placed around the grafted area in such a manner that they do not interfere in any way with the edges. This method is suitable only on small flat surfaces where there is little danger of serous exudates lifting off the grafts. Ideal patients who will be quiet and realize the importance of a good result contribute to the success of this method.

2. Personally, I prefer the closed method, since we have been using dental wax for covering the grafts. An impression of the area to be grafted is made with sterile dental wax. The Thiersch graft is placed around, or over, the wax, and then inserted or placed over the denuded area. The graft, under suitable conditions, may be placed and then covered with the dental wax. The wax is then carefully covered by a dressing held in place by adhesive, and the whole covered with a well-placed roller bandage.

The dressings can be removed on or about the fourth day. The wound is carefully cleaned with pledgets of cotton or applicators moistened with boric acid or bichloride solution, being very careful not to remove the grafts. If the graft looks nice and pink, and no secretions are present, the dressings may be discarded, the wound dusted over with aristol, and the open-air treatment used. Later, as the grafts begin to dry, it may be advantageous to cover them with sterile vaseline. About this time, or a little later, massage of the grafted area and surrounding skin is very helpful, as it also tends to soften the graft and renders it more movable, and it assumes more rapidly the appearance of the surrounding skin.

CONCLUSIONS

1. A photograph should be taken before and after each operation.

2. Strict asepsis and a properly prepared field.

3. Pedunculated flaps should be used wherever possible.

4. Use the method with which you are most familiar.

5. The Thiersch method for grafts is the one of choice around the eyelids on account of its simplicity.

6. The closed method of after-treatment has more advantages for most cases.

7. Always aim at overcorrection in all graft transplants.

8. The use of vaseline makes cutting of graft much easier.

9. Keep graft from becoming too dry afterward.

THE NEW JOURNAL

The California State Journal of Medicine for many years has justly stood very high in the annals of state journalism. It has grown so that it is not possible to make any further expansion without changing the type of binding. With the January issue the Journal comes out with an entirely new cover and a new type of binding. With this new binding and method of covering, we enter the field of larger journalism from a mechanical standpoint.

While for economic reasons, the first few numbers of 1922 will be limited to 96 pages and cover, it is expected that beginning with the May number we will have 108 pages, and we hope to enlarge to 116 pages before the end of the year. This advance, of course, will increase somewhat the expense of the Journal, which we hope to offset by an increased income already provided for from members and by a slight increase in the space devoted to advertising.

The editor invites and welcomes correspondence and constructive criticism of any character tending to make the Journal better.

THE DIAGNOSIS AND TREATMENT OF INTRACRANIAL HEMORRHAGE OF THE NEW-BORN — REPORT OF A CASE *

By EDWARD B. TOWNE, M. D., and HAROLD K. FABER, M. D., San Francisco.

Important advances have been made, in recent years, in the knowledge of the causes of intracranial hemorrhages of the newborn, and in the diagnosis of the different varieties. Treatment has also made notable progress in some forms, particularly in those due to a general hemorrhagic diathesis and in those occurring in the posterior cranial fossa. The object of this paper is to attempt to correlate pathology and symptomatology with the various methods of treatment. A case is reported that illustrates successful treatment of a lesion that was correctly localized, as well as needless surgery due to failure to apply all the possible diagnostic methods.

Etiology.—Recent papers by Warwick [1] and Rodda [2] have reviewed the theories of the causes of intracranial bleeding. The hemorrhages may be divided into two main classes, those due to trauma incurred in the passage of the child through the birth canal, and those due to disease of the child. The first class is purely traumatic; the second has no relation to labor, and the most frequent underlying cause is the hemorrhagic diathesis. Green [3] was the first to appreciate the importance of the second factor. Warwick demonstrated the condition in eight of eighteen cases of intracranial birth hemorrhage that came to postmortem examination.

Diagnosis.—An attempt must be made to answer two questions before these cases can be intelligently treated. First, is the intracranial hemorrhage of traumatic origin, or is it one manifestation of the hemorrhagic diathesis? Second, what is the location of the hemorrhage? Neither question can be answered in every case. If the infant shows evidences of multiple hemorrhages, such as a cephalohematoma, petechiæ in the skin, or bleeding from one of the body orifices, the diagnosis of hemorrhagic disease is easily made. But these signs do not always appear. Five of Warwick's eight cases of intracranial bleeding caused by the hemorrhagic diathesis vomited blood, but the other three showed no clinical evidence of the multiple clots that were found post-mortem. Determination of the coagulability of the blood has proved helpful in making the diagnosis. Rodda [4] determined the curve of coagulation and bleeding times in the first few weeks of life, and showed [2] that in hemorrhagic disease of the newborn the times were prolonged.

The second question is of greater importance, for the selection of the proper method of treatment depends on correct localization even more than on differentiation between the traumatic and diathetic types. Seitz' [5] localizing classification is the most useful. He divided the hemorrhages into three groups—the supratentorial, the infratentorial, and the intraventricular. Various combinations are found; thus in Warwick's eighteen cases, six had hemorrhage over one cerebral hemisphere, three over cerebrum, cerebellum and in the dura, three over cerebrum and cerebellum, one over cerebrum, cerebellum and in the ventricle, one over cerebellum, two in the dura alone, and two in the ventricle alone. Her series emphasizes the fact that the most common site is supratentorial, for thirteen of these eighteen cases had hemorrhage over the cerebrum alone or in combination. Cushing [6] called attention to the unprotected pial veins as they travel from the cortex to the longitudinal sinus as particularly liable to injury from overlapping of the parietal bones during parturition. In attempting to diagnose the location of the bleeding, it is proper to consider the odds as in favor of the source being partly, if not entirely, the pial veins that empty into the longitudinal sinus.

The symptoms may be clear-cut and localize the trouble beyond question, but frequently they are confusing, or even misleading. Eliminating those that cannot be resuscitated, most patients cry and appear more or less normal for a time. After an interval of hours or days, symptoms appear. The infant may first refuse the breast, or cry continually, or be drowsy, or show increased reflex excitability, or have sudden attacks of asphyxia with respiratory disturbances. The fontanelle becomes full and tense, and there are convulsions in practically every case. In attempting to evaluate these symptoms it should be remembered that the largely non-medullated brain of a new-born infant makes him little more than a spinal animal, who will live under most adverse conditions provided the medullary centers are not too much implicated. So a large hemorrhage over the cerebrum may give no signs beyond those of increased intracranial pressure, while a small hemorrhage below the tentorium may be rapidly fatal. Disturbances of respiration with cyanosis, generalized convulsions and rigidity of the limbs point to infratentorial bleeding; while convulsions involving first or only one side, or palsies of face, arm, or leg, or lateral deviation of the head or eyes indicate a supratentorial lesion. There seems to be no way to detect an intraventricular hemorrhage from the symptoms.

Spinal puncture gives valuable evidence in localizing the bleeding. When the hemorrhage lies over a cerebral hemisphere the fluid contains little blood, and the withdrawal has no effect on the progress of the case. On the other hand, an infratentorial hemorrhage gives fresh blood, usually in considerable quantity, and removal is frequently followed by temporary or even lasting disappearance of cyanosis, disturbed respiration and convulsions.

Subdural puncture as a diagnostic procedure was suggested by Henschen [7] and, apparently independently, practiced by Gilles [8]. A spinal puncture needle is introduced at the lateral angle of the great fontanelle and passed under and parallel with the parietal bone. Henschen recommended this puncture to confirm the diagnosis of a supratentorial hemorrhage and to prove which side was involved. This is unquestionably a most valuable method, provided it does no harm. If there is a

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

subdural clot near the longitudinal sinus, a carefully directed needle need not damage the cortex. But, remembering that the central fissure lies very little posterior to the fronto-parietal suture in the newborn, one wonders whether a negative exploration might not lacerate the motor area. In Case 2 of Green's second paper [9] a negative puncture gave no ill results. Hemorrhage into the lateral ventricles can be confirmed or ruled out by ventricular puncture through the outer angles of the great fontanelle, but this procedure also carries some risk of injuring the motor cortex.

Visual inspection of the dura under the fontanelle after incision of the scalp enabled Murphy [10] to detect clots over the cerebral cortex on both sides of the longitudinal sinus. This apparently neglected method ought to prove of great value, for it avoids the dangers of subdural puncture and requires only a short scalp incision, which may be extended for an osteoplastic exposure on either side.

Three cases reported by Potocki and Levant [11] illustrate the difficulties of diagnosis, even with apparently definite clinical localizing signs, without the help of fontanelle inspection or exploratory puncture. The first two cases showed motor signs pointing to a clot over one cerebral cortex, but both had intraventricular hemorrhage only. The third case had similar signs and was diagnosed hemorrhage into the ventricles, but at post-mortem examination no intracranial hemorrhage of any kind was found. Subdural puncture and fontanelle inspection would have been negative throughout, but ventricular puncture would have made possible a positive diagnosis in the first two cases.

Treatment.—Intracranial hemorrhages have been treated by four methods: (1) spinal puncture, (2) subdural aspiration or drainage, (3) removal of the clot through an osteoplastic window, and (4) measures designed to increase the coagulability of the blood.

(1) *Spinal Puncture.*—This was first proposed and practiced by Devraigne,[12] who reported a case in which the convulsions stopped, leaving the infant in apparently normal condition. Dutreix [13] recorded five cases, of which three recovered and two died following removal of bloody fluid by spinal puncture. Henschen [7] saw that spinal puncture gave good results in infratentorial, but could do not good in supratentorial hemorrhages. Green's [9] Case 1, a typical infratentorial hemorrhage with apnoea, cyanosis, nystagmus and convulsions, cleared up with repeated removals of bloody cerebrospinal fluid and appeared normal on the fourth month. Brady [14] treated three cases with spinal puncture. Two were apparently normal at three years and fourteen months, but the third continued to have convulsions and developed spasticity; post-mortem examination at nine months showed adhesions and flattening over a small area of the cerebral cortex. Foote [15] had six recoveries and one death in infants showing respiratory distress and blueness, with or without convulsive phenomena, treated by spinal puncture and subcutaneous injection of horse serum or thromboplastin. One detailed case was an instance of hemorrhagic disease of the new-born. Good results are also recorded by Lippman [16] and Vaglio [17]. Spinal puncture, on the other hand, has had no influence in numerous cases in which it was used only for diagnostic purposes, and post-mortem examination has usually shown a clot over the convexity of the cerebrum. Thus Rodda's [2] Case 5 had a large hemorrhage over the entire right hemisphere, as well as smaller ones in the pericardium and the spinal canal, and died from intracranial pressure in spite of spinal puncture and repeated subcutaneous injections of whole blood. Rodda recognized that spinal puncture gave results only when the bleeding was below the tentorium.

(2) *Subdural Aspiration or Drainage.*—If aspiration through the great fontanelle is used as a therapeutic measure, it amounts to the same thing as drainage at that point. Gilles [8] so used it, but his patient continued to have convulsions and died at nine months. Henschen [7] advocated it in mild cases, and Green [3] thought that if considerable blood were aspirated operation might be postponed or omitted. Murphy [10] was the first to evacuate a hemorrhage over the cerebral cortex through a short linear incision. He first exposed the anterior fontanelle and saw through the dura evidence of hemorrhage on both sides of the sinus. After turning down an osteoplastic flap and removing the clot, the patient's condition seemed to contraindicate a similar procedure on the opposite side, so the fluid blood was partly evacuated through a short incision lateral to the longitudinal sinus. The infant made a good recovery, and the cerebral condition was considered normal when it died of gastro-enteric disease at five weeks. Simmons [18] added rubber tissue drainage to Murphy's evacuation of a subdural clot through a short incision. He reported two cured cases, one of which gave an excellent result thirteen months after bilateral drainage. He saw the danger of adhesions from the portion of the clot that was not removed, but said that his operation was rapid, easy, and justified by the results. He thought that neither case would have survived Cushing's osteoplastic procedure, which he recognized as the more thorough and desirable method. Green [3] recorded a case so treated by Murphy, in which post-mortem examination showed a clot overlying the cerebral convolutions and extending down into the longitudinal fissure. Cumston [19] and Green [9] have each reported a good result with the Simmons operation. Green felt that incision and drainage gave adequate relief, and was preferable to the osteoplastic operation.

(3) *The Osteoplastic Operation.*—In 1897 Chipault [20] said that the usual clot over the upper motor cortex was a surgical problem, and suggested that its removal would be easy and ought to give good results. Cushing [6] was the first to successfully evacuate a clot through an osteoplastic window. He [21] reported in 1908 that he had thus operated on nine cases, with four apparently perfect recoveries. Seitz [22] and Meara and Taylor [23] reported two cases in which clots over the cerebrum were removed, but both died, and post-mortem examination showed that there was also infratentorial bleeding. Murphy and Torbert [10] had a recovery following evacuation of clots by Cushing's procedure on one side, and through a

short dural incision on the other. Hubbard's [24] case, a fatality, is not easy to classify. He found clots over both cerebral hemispheres, probably through small decompressive openings, and cortical laceration resulted from attempts to enlarge the bone defects. Bailey [25] removed a clot from the motor cortex, but could not suture the dura or bring the bone flap into position because of cerebral herniation. His patient had a facial palsy and a flaccid arm on the thirtieth day. Strachauer [26] has done four craniotomies for cerebral hemorrhage in infants; one died at eight weeks, and the other three were seemingly normal. Rodda [2] reported two of Strauchauer's cases in more detail. One (Case 8) was a typical Cushing procedure, the other (Case 9) was a "decompressive operation," which apparently did not locate the clot, but which was followed by a good result.

The osteoplastic operation has been done fifteen times (Cushing 9, Seitz 1, Meara and Taylor 1, Murphy and Torbert 1, Strauchauer 1, Bailey 1,

Fig. 1. Lateral view of head at nine months, to show brachycephaly

Towne and Faber 1), with eight recoveries. Two other cases of Strachauer's and one of Hubbard's cannot be classified, because of lack of detail.

(4) *Measures Designed to Increase the Coagulability of the Blood.*—Rodda [2] showed that delayed coagulation and bleeding times can be reduced to normal by repeated subcutaneous injection of whole blood, and he felt that this reduction was essential prior to surgical intervention. In two cases successfully operated on by Strachauer, Rodda thought that the blood injections added to the chances of surgical success. Foote [15] had six recoveries in seven cases, treated by spinal puncture and injection of horse serum or thromboplastin.

Case Report.—Male, born July 11, 1920, at full term. The confinement was attended by a Japanese midwife. The mother was in labor ten hours, and delivered herself without assistance. At a later date pelvic measurements, for which we are indebted to Dr. A. V. Pettit, showed moderate lateral contraction of the inlet. The child cried immediately after birth, and was said to be a very strong baby by the midwife. He nursed and appeared well until the third day, when he began to vomit and to refuse nourishment. On the sixth day, July 17, the baby entered hospital as a feeding case.

Examination showed a markedly dessicated infant weighing 2740 gms. The pupils were equal, the eyes and head were turned to the right. The anterior fontanelle was tense and bulging. There was a left facial paralysis, with no motion of the mouth on crying, and inability to close the eyelids. The arms and legs were spastic. Temperature, 98.6°; pulse, 80. That afternoon he had a general convulsion lasting about ten minutes, with cyanosis and rhythmic respiration. On July 18 the pulse was 130, respirations were regular, and the color was good. Attempts to feed with a dropper being unsuccessful, gavage was used. Slight twitching of the left arm was observed twice. A subcutaneous injection of whole blood was given. July 19, spinal puncture gave 2 cc. of straw-colored fluid. Most of the food given by the tube was regurgitated. July 20, the child was somnolent. Aspiration of the left lateral ventricle through the left

Fig. 2. Appearance at nine months. Note that the finger movements are not restricted

angle of the fontanelle gave 2 cc. of slightly reddish fluid. Supraorbital pressure did not make him cry, but caused him to move the right face, arm and leg. A diagnosis of hemorrhage over the right cerebral hemisphere was made.

July 21. Operation. The child was wrapped in cotton and lightly etherized. The right parietal bone was turned down in an osteoplastic flap. The dura was tense, immobile and deep blue in color. A flap of dura was reflected and a clot, 1.5 cm. thick, was removed from the cortex with wet cotton swabs and irrigation. The clot extended to the falx, over the frontal and occipital poles and over the temporo-sphenoidal lobe, thinning as midline became more distant. It was partially removed from under the bones with spoon and irrigation. Near the midline and toward the anterior end of the bone opening a large bleeding pial vein was ligated. After removal of the clot the brain still bulged markedly through the opening in the dura. The dural flap could not be brought back into place, and an attempt to swing it up by a plastic incision did not prove successful. The head was lifted off the table with skin clips placed about

the outer margin of the scalp incision. This manoeuvre allowed the brain to drop back into the collapsible cranium so that the dura could be sutured in place. The pericranium and scalp were closed without drainage. Twenty-five cc. of whole blood were given subcutaneously. Following operation the baby began to take his feedings better, and the weight increased to 3200 gms. on July 29. Blood was given subcutaneously on July 22 and 30. The palsy of the left face cleared up rapidly. The conjugate deviation of the eyes, spasm of right neck muscles and rigidity of left arm and leg disappeared gradually, until on July 29 a clenched left hand was the only evidence of right cortical irritation. The spasticity of the right leg and arm showed no diminution. It was thought that a smaller subdural clot lay over the upper portion of the left cerebral hemisphere.

Second operation, July 30. The left parietal bone was turned down, showing a normally colored dura. A small incision at the upper aspect of the defect allowed normal cerebro-spinal fluid to escape. There was no hemorrhage. Closure. In four days after the second operation the right-sided spasm disappeared entirely. He took his feedings well, and after a drop to 3000 gms. he gained weight steadily, going to 3400 gms. on August 19 when he was discharged from the hospital. He seemed of normal intelligence, taking the bottle well and noticing lights and motions. There was a tendency to keep the fingers clenched in the palms of both hands, but at times they were relaxed; and as the left cortex was known to be normal this was thought to be of no significance. In October, 1920, when three months old, he weighed 5050 gms. He no longer showed clenching of the fingers. In February, 1921, at seven months, he weighed 6125 gms. The head was high, wide, and short in the antero-posteror diameter. The biparietal diameter was 12 cm.; the suboccipito-bregmatic 12.5 cm. He did not sit up, or hold the head up well. He recognized his parents, and responded to lights and moving objects, but did not turn promptly to loud sounds. It was felt that he was normal mentally, as far as could be told at that age, but perhaps slightly retarded in muscular control. In April, 1921, at nine months, the child was well nourished and active. (Figs. 1 and 2.) The brachycephaly was quite marked. He played with toys, reacted quickly to moving objects and sounds, sat up alone, and made sounds but no words. No motor or sensory abnormality could be made out. There had been no convulsions.

Discussion of Case.—In this instance there was no difficulty in making the diagnosis of a clot over the right hemisphere, for the symptoms were unusually clear-cut; tense fontanelle, deviation of the head and eyes to the right, palsy of the left face and spasticity of the left limbs, old blood in the cerebro-spinal fluid, and general convulsions. The pathology underlying these signs was accurately forecast, and the only surprising fact was the great size of the clot. The identification of a ruptured pial vein near the longitudinal sinus as the probable source of the bleeding, though noted in Cushing's case 4 at autopsy, has not been previously reported as an operative finding. A matter of considerable technical interest came up in the first operation. Because of bulging of the cortex it was impossible to suture the dural flap in place. Cushing noted this difficulty, but he attributed it to edema of the brain, and advised counteracting it by lumbar puncture. In our case it did not appear possible that lumbar puncture could reduce the tension sufficiently to allow closure. But cerebral edema could have played only a minor role, for the event proved that the cerebral extrusion was largely of mechanical origin. The cranium after closure of the suture lines is a solid box, but in the newborn infant it will collapse if a window is cut through the dura mater. When the baby's head was gently lifted from the table by the edges of the scalp incision the brain dropped back enough to allow closure of the dural incision. It seems probable that this simple manoeuvre will, in other cases, solve the one technical difficulty of the operation. A scalp tourniquet is, of course, inadvisable in these cases.

The second operation did no apparent harm, but it was quite unnecessary. The diagnosis of a clot over the left hemisphere was made on the fact that, though the spasticity of the left leg and arm disappeared rapidly after the first operation, the right leg remained just as rigid as it had been on admission, and the right arm showed only slight improvement. Four days after negative exploration of the left cortex the spastic condition of the right limbs had disappeared. The exploration could not account for this change. A possible explanation may be that on the day before the first operation the lateral ventricle was tapped through the left angle of the great fontanelle. It is conceivable that some slight edema or hemorrhage from this puncture may have temporarily involved the motor cortex for the right arm and leg. Had we been familiar with subdural puncture or inspection of the fontanelle after incision of the scalp, the possibility of a left cortical hemorrhage could have been ruled out. Inspection rather than puncture would seem to be the method of choice, for there must be a definite risk of damage to the motor cortex from a negative puncture.

The condition of the child at nine months was encouraging. Nothing abnormal could be found except a tendency to brachycephaly. Unfortunately, he was taken to Japan and will not come under observation again, so that the final physical and mental result will not be known.

SUMMARY

Rational treatment of intracranial hemorrhage of the newborn must be based on a correct diagnosis of the cause and site of the bleeding. In addition to the clinical symptoms, spinal puncture, inspection of the fontanelle after scalp incision or the less desirable subdural puncture through the fontanelle, ventricular puncture, and determination of the coagulability of the blood are valuable aids in diagnosis. Infratentorial bleeding is best treated by spinal puncture, for a hemorrhage of any size is rapidly fatal, and puncture appears to be sufficient in small hemorrhages. Supratentorial hemorrhage should be treated by osteoplastic resection of the parietal bone and evacuation of the clot. Aspiration or drainage of such hemorrhages does not insure against future trouble from adhesions and cyst formation, and should be used, if at all, only as a preliminary step to the Cushing operation. Spinal puncture and aspiration of the ventricle are indicated in the intraventricular hemorrhages. In all cases, but especially when hemorrhagic disease is diagnosed, subcutaneous, intramuscular or intravenous injection of whole blood, controlled by coagulability tests, should be given. The intracranial clot of the diathetic cases calls for the same surgical treatment as does the clot of traumatic origin. In the case reported a clot over a cerebral hemisphere was diagnosed and removed, but misleading clinical symptoms and failure to inspect or puncture the other side of the fontanelle led to a needless exploration of the opposite hemisphere. Except for brachycephaly, the child appeared normal at nine months. The only technical difficulty of the osteoplastic operation is closure of the dural flap. In our case this was demonstrated to be due to collapse of the skull,

and was easily remedied by lifting the head by the scalp edges, thus allowing the brain to drop back into place. A scalp tourniquet should not be used, for its pressure would increase cerebral herniation through the dural opening.

OVARIAN AUTOTRANSPLANTATION *

By F. R. GIRARD, M. D., San Francisco.
Assistant Clinical Professor of Gynecology Stanford University Medical School, Attending Gynecologist San Francisco Hospital, Stanford Division

My experience in ovarian transplantation has been limited entirely to autotransplants and the results in ten cases will be given. The two circumstances under which these operations were performed were:

First: Three cases of hysterectomy with double salpingo-oöphorectomy and transplantation of parts of one or both ovaries into the abdominal wall. In all cases the grafts took and in all cases there has been periodic enlargement and varying degrees of tenderness in the grafts. All cases have had ablation symptoms since operation, but these symptoms have been markedly lessened during the period that the grafts showed activity. These findings are contrary to those of Tuffier, who states that while the grafts increase in size monthly for two or three years after hysterectomy, it is without any benefit to the patient.

Second: Six cases of double salpingo-oöphorectomy without hysterectomy and with autografts from either one or both ovaries into the abdominal wall, and one case of double salpingo-oöphorectomy without hysterectomy with autotransplants into wall of uterus. The justification for leaving the uterus and transplanting the ovaries is: the suppression of pain which follows retained ovaries with damaged blood supply and extensive denudation of the surface of the ovary, permitting adhesions and cystic degeneration and, most important of all, the preservation of menstruation, because that function is absolutely necessary along with ovulation to ensure the patient freedom from the distressing trophic, congestive and nervous symptoms which follow suppression of menstruation.

Surgical Technique: The technique of autografting is simple indeed and adds no extra risk to the operation. In all cases the ovaries were completely removed and the uterine end of the tube resected by a V-shaped incision into the cornua of the uterus. The ovaries were then wrapped in gauze and placed in a vessel containing normal salt solution at about 100° F. The operation and peritoneal toilet were then completed and in some cases a pocket was made, by blunt dissection, between the peritoneum and the under surface of the rectus muscle, on either one or both sides of the incision, according to the number of grafts to be used. The ovaries were then carefully inspected and areas of cystic degeneration were culled out. The remaining ovary, when possible, was cut into disks 2x2x½ cm. and from one to three of these disks were transplanted into the already prepared pockets. No sutures were used to hold the grafts in place. On removing the grafts from the saline solution, one is at first apt to be rather startled at the pale, lusterless and shriveled appearance of the grafts, but this apparently does not interfere in any way with the success of the grafts. The abdominal wall was closed in the usual manner.

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

In other cases the grafts were inserted into a bed prepared on top of the anterior sheath of the rectus muscle, and in the subcutaneous fat, three or four cm. to either side of the incision.

I have never used grafts of the whole ovary and believe that better results will be obtained from multiple or seedling grafts, because a much larger surface is obtained which insures a better blood supply.

In one case the grafts were embedded into the cornua of the uterus after removal of the tubes. No matter where the grafts are embedded, the results seem equally good, provided the graft is asceptic, the field has an adequate blood supply, and the site chosen permits the graft to enlarge periodically without compression and consequent pain. I believe that the suggestion of Whitehouse, that the ovarian tissue be left in contact with the body fluids within the peritoneal cavity until required for grafting, to be a good one and in future I will place the grafts in the pouch of Douglas while completing the pelvic work and removing them just prior to closing the abdomen.

Average age was 30½ years, youngest 20 years and the oldest 41 years.

Summary of Cases: Immediate results of operation were uniformily good. Patients who had been grafted show no symptoms or complications different from other patients subject to pelvic operation.

Ultimate Results: As the time elapsed since the first operation is only 18 months, results for the first year and a half only can be given.

First—Cases with hysterectomy. All showed ablation symptoms varying from slight to moderately severe. All cases showed activity of grafts as indicated by periodic enlargement and tenderness of the grafts and amelioration of the ablation symptoms at this time. In none of the cases in which hysterectomy was done have the patients been entirely free from the symptoms of artificial menopause. Ablation symptoms appeared at the following times after operation: Three weeks, six weeks and four weeks, respectively.

The symptoms of menopause can be classified as slight in two cases and moderately severe in one case. In none of the cases are the symptoms constant and all show a tempering of these symptoms by the presence of the ovarian grafts.

Second—Cases without hysterectomy. 1. Time after operation of appearance of menstruation:

Case 1. Menstruation 4½ months, scanty at first, now moderate and regular, no pain.

Case 3. Menstruation 6 months, regular, 1½-day flow.

Case 4. Menstruation at 9 weeks after operation, scanty at first, now regular, 7 days, no dysmenorrhoea.

Case 5. Unable to trace patient.

Case 7. Menstruation at 5 weeks after operation, scanty at first, now heavy and regular, no dysmenorrhoea. On March 7, 1921, patient had her regular normal five-day flow. On March 23, 1921, she began to flow moderately again, but without pain. This continued for 10 days, when she was sent to San Francisco Hospital and curetted by Dr. Gibbons. Pelvic examination negative except for slightly enlarged uterus. Microscopic examination of curettings showed normal menstruating endometrium. Wassermann taken at time of first operation was doubtful, but is XXX at present, which probably accounts for the metrorrhagia.

Case 8. Menstruation at 3 months after operation, scanty, one day, no pain.

Case 10. Menstruation at 5 months. Scanty at first, now moderate flow, no pain.

2. Effect on ablation symptoms: Case 1. Severe until menstruation. Now only occasionally and very slight. Case 4. Slight flushing and nervousness until menstruation. Now only occasionally and slight. Thinks she is not more nervous than before operation. Case 7. No symptoms of artificial menopause. Case 8. Moderate flushing and nervousness until menstruation. Now only very slight symptoms, which are getting milder all the time. Case 10. Moderate symptoms for four months after operation. Now free for as long as two months at a time. Symptoms only occasional and slight.

CONCLUSIONS

1. Autografting of ovaries is a perfectly safe and rational procedure and is indicated, except in cases of malignancy or ovaries grossly infected in all patients requiring removal of the ovaries, with or without hysterectomy.

2. Ovaries requiring removal are: (a) Badly traumatized ovaries with much raw surface on capsule; (b) ovaries showing considerable cystic degeneration; (c) ovaries having a impaired blood supply.

3. Cystic degeneration of ovaries is no barrier to autotransplantation and ovaries removed in conditions of pyosalpinx can be transplanted, provided the ovaries themselves are not grossly infected.

4 Autotransplantations certainly lessens and delays ablation symptoms followig castration and in some cases affords complete freedom from symptoms of artificial menopause. Autotransplantation lets patient down easy.

5. That the autografts functionate is shown by periodic increase in size and tenderness of grafts with amelioration of ablation symptoms, and when the uterus remains, by menstruation.

6. When the ovaries are found suitable for transplantation, when possible the uterus should be allowed to remain, myomectomy done in fibroids, and as the body of the uterus adjacent to the tubes and the cervix are the two areas of persistent infection in inflammatory disease, the fundus should be resected and the cervix treated by deep cauterization or a Sturmdorf tracheloplasty, or amputated when this condition is present.

7. It is an established fact that a small portion of an ovary successfully engrafted anywhere furnishes to the subject of the graft the secretion or influence which preserves her sexuality, and prevents atrophy of the genital organs and other changes in the individual that are coincident with complete castration.

8. After ovarian transplantation certain cases show marked increase in sexual stimulation.

9. Reasonably healthy and undamaged ovaries should be left in situ with or without the uterus and autotransplantations should be used to carry on the physiological functions of the ovary only in those cases where, for reasons given above, both ovaries must be removed.

In studying the literature in regard to ovarian transplantations, one is impressed with the amount of experimental work which has been done along these lines, both in this country and in Europe. Although the findings of many of these investigators have been widely divergent, they all agree that the autotransplant is the method most promising of success, and that homografts and heterografts are successful in a much less degree. Also, the results after ovarian transplantation are de-

cidedly more brilliant in animal experimentation than when done in the human subject. Franklin Martin of Chicago in 1915 gave an excellent summary of the work done by various investigators in ovarian transplantation.

To quote the conclusions of various experimentors—Benthin thinks that the effects of ovarian transplantation are good, but that the experimental results are more successful than the therapeutic. Transplantations of small bits of ovary, while it gives good results, does not guarantee their permanency. Homotransplantation should be undertaken only in very young individuals, and in homotransplantations it is very important that the organs should be transplanted immediately after removal from the donor.

Stocker reports two cases in which he did an autotransplantation of part of an ovary. In one patient, age 28, a pan hysterectomy was done for a gonorrheal condition with extensive adhesions. One of the ovaries was cut out of the excised mass and sliced into disks only two or three mm. thick. An implanted disk of this kind grows into place very rapidly, as blood vessels soon grow through it. The bed into which it is implanted must be rich in blood vessels and must protect the graft from injury from without. Stocker implanted the graft in a fold of peritoneum and wound healed by primary union. An epinephrin test was made on the fifth day and there was no specific response as there is when the inhibiting influnce of the ovaries is entirely withdrawn. The patient never had any symptoms of artificial menopause and was restored to health after five years of semi-invalidism. Three years later an intestinal tumor necessitated a laparotomy. The disk of ovarian tissue was found to be about the size as when implanted and very vascular. In his second case the tube and ovary had been removed on one side for ruptured tubal pregnancy and two years later on the other side for the same condition. At the second operation a disk of ovary was transplanted into a fold in the peritoneum and menstruation continued regularly and patient's condition was excellent.

Norton agrees with Tuffier that cystic degeneration of the ovary is no bar to transplantation and he has grafted ovaries that were almost entirely cystic, cutting out the medium sized and larger cysts and implanting the residue. Some of these ovaries seemed hopelessly diseased and had been causing much pain over a long period of time. In these cases the patients were free from pain and menstruated regularly. He considers the operation one of the most satisfactory advances in modern surgery and recommends it in diseases of the ovaries. It should always be done instead of double oöphorectomy in idiots, defectives and criminals. Except for the fact that it does not allow pregnancy, it fulfills all the requirements of an ideal operation. It can be easily and quickly done. The functions of the ovary, both as to internal secretion and menstruation, are maintained and at the same time the ovary is placed in a clean, healthy bed completely protected from subsequent attacks of gonorrhoeal infection. With a new and diminished blood supply sclerosis and cystic degeneration are prevented or retarded. A small portion of the ovary retained within the abdomen seems to retain the power of the organ as a whole.

Lydston gives a summary of his previous work on sex gland implantation. He believes that the sex gland harmone is the most powerful cell stimulant, nutrient, and regenerator known to medical science and that sex gland transplantation preserves harmone production for a long time. He believes that certain physiologic and therapeutic advantages are permanent. In his cases the implanted tissue has never disappeared in less than twelve to eighteen months. Microscopic sections of the implanted gland show regeneration of circulation and the interstitial connective tissue which probably produces the so-called internal secretion.

Blair Bell found that if ovaries be excised and transplanted into the muscle of the uterus or abdominal wall, atrophy of the genital ducts will not occur. He found that the follicles first become cystic and then degenerate; that is to say, they ripen; but if completely buried cannot expell the contents and therefore become cystic and retrogress. He also noted that in the rabbit, if only the central portion of the ovary, which contains no follicles, be implanted, the interstitial cells of which the graft is composed, can maintain the integrity of the uterus alone. It is possible that ovarian transplantation in general and of the interstitial cells in particular, are capable of keeping normal the uterus, mammæ and other endocrine organs and the general metabolism, in the female. He concludes that it is not the ovaries alone which influence the female characteristics and genital functions, except in regard to the production of ova. The ovaries are only a part of the system to which most, if not all, of the other endocritic organs belong and in which these other organs figure with as great importance as the ovaries themselves.

In twenty-three cases of hysterectomy with autotransplantation of ovaries into the abdominal wall, done by Graves, he found that the ablation symptoms were almost identical with those in completely constrated women. He has had better results in treating ablation symptoms with ovarian extract and his results were better with extract of the whole ovary than when corpus luteum was used alone. He thinks that there is certainly an ovarian secretaion that is not produced in the corpus luteum, for profound effects are produced by removal of the ovaries before puberty when there are no corpus lutea. He does not know whether this early secretion originates in the follicles or the highly differentiated connective tissue of the ovarian stroma. The cause of vaso-motor disturbances following removal of the ovaries, Graves thinks to be due to the influence of some other organ of internal secretion, which has been rendered abnormally active by the loss of the balancing power exerted by the ovarian secretion. It is conceivable that the thyroid is made overactive by the removal of the ovaries and that the ablation symptoms are manifestations of hyperthyroidism.

Tuffier affirms that symptoms of artificial meno-

pause are due almost exclusively to the suppression of the menstrual function. Modern research has demonstrated the close connection and reciprocal action of the various glands with an internal secretion and their reciprocal changes when one functionally drops out. Therefore, special efforts should be made to preserve the balance between the various ductless glands. He transplants the ovaries into the subperitoneal tissue no matter how sclerocystic the ovaries are, provided they are aseptic.

He found that from three to five months later the grafts showed phenomena of congestion and about one week later menstruation began. In the interval between menstruation the grafts were scarcely palpable. In a report of 19 of 44 cases all but one menstruated in from three to seven months. During the period of latency all had symptoms of menopause which cleared up with restoration of menstruation. In autografts when the uterus was removed there was monthly ovulation, but the symptoms of menopause persisted. He conserves the uterus wherever possible when autografting ovaries, or does a partial hysterectomy, leaving enough of the body of the uterus to carry on the menstrual function. He regards these conservative measures especially indicated in cases of excessive thyroid function or when the symptoms of menopause are liable to be unusually severe and protracted with hyperthyroidism. Tuffier, in a paper presented at the London meeting of the Clinical Congress of Surgeons of North America in 1915, again insists that the beneficial effects of ovarian transplantation are due to the resulting menstruation and that ovulation without menstruation (as when uterus is removed) is without value.

He states: "My purpose in addressing you on this subject is to lay before you my experience in grafting of ovaries in the hope that menstruation might be preserved after operations for salpingitis and fibroids of the uterus."

CASE REPORTS

(1) Mrs. G. Age 33. **Operation:** September 3, 1919. Dilatation and curetage, deep cauterization of cervix, bilateral salpingo-oöphorectomy. Autografts left ovary into pockets between peritoneum and under surface rectus muscle on either side of incision. **Pathology:** Intraligamentous cyst right ovary size of small orange. Left ovary size of walnut and cystic. Both tubes closed, adherent and hydrosalpinx present.

Examination: September 29, 1920. Grafts not palpable. Patient has noticed slight tenderness of wound before menstrual periods. Patient had quite severe ablation symptoms until menstruation appeared January 12, 1920, when she had a profuse flow for one day. Since that time she has had only occasional flushing and at times she is free for as long as one month. Flows regularly every month from two to three days and has no dysmenorrhoea. In May flowed only one day and about that time flushing and nervousness were more severe than at any time since operation. That was the only time since menstruation began that ablation symptoms have been at all severe or that menstruation was diminished.

Vaginal Examination: Uterus normal size and position, freely movable, no tenderness, no pelvic masses. Patient states that since her operation sexual desire has been considerably increased and has remained so for more than one year.

(2) Mrs. C. B. Age 27. **Operation:** October 19, 1919. Hysterectomy, supravaginal, bilateral salpingo-oöphorectomy, separation of extensive intestinal and omental adhesions. Autotransplantation of ovarian grafts. **Pathology:** Both tubes buried in adhesions from previous pelvic peritonitis. Right tube closed, thickened, convoluted and adherent to right ovary and posterior surface of broad ligament. Left tube adherent to sigmoid and posterior surface of uterus, omental adhesions to uterus and adnexa. Ovaries enlarged, cystic and chronically inflammed.

Bilateral transplantation of ovarian grafts in pocket made between posterior surface of rectus muscle and peritoneum. Wound healed, primary union.

April 2, 1920. Ovarian grafts definitely palpable. Patient has thin abdominal wall. Patient states grafts vary in size, at times become enlarged and tender, remaining so for several months. During this time she feels much more energetic and has only slight flushing and some nervousness. Two months previously grafts were hardly palpable and patient had quite severe flushing, was extremely nervous and easily tired.

September 28, 1920. Grafts about same size as when examined last. Patient states that grafts enlarge and become tender at irregular intervals, during which time she feels better and is much less nervous. She now looks forward to those intervals of remission from flushing and nervousness and can tell when they are coming by the condition of the grafts.

(3) Miss C. J. Age 35. **Operation:** December 17, 1919. Partial hysterectomy, leaving lower third body of uterus. Bilateral salpingo-oöphorectomy, ovarian transplants from left ovary in abdominal wall. **Pathology:** Multiple submucous and intramural fibroids of upper half of uterus. Small dermoid cyst right ovary. Cystic degeneration of left ovary. Three sections from left ovary transplanted into abdominal subcutaneous tissue. Two pieces on right, one of left side.

Examination: April 20, 1920. Grafts feel larger than at any time since operation, slightly tender. For last two months patient has had flushes and dizzy spells. Have been less since grafts have enlarged. Feels as though she were going to menstruate.

June 20, 1920. Menstruated for one day. Moderate flow, very few flushes for past two months. Feels fine. Much less nervous. Grafts enlarged in May and again one week before flow commenced.

July, 1920. No menstruation but felt as though she would. Feels fine.

September 18, 1920. Flowed 1½ days. No pain. No flushes or nervous symptoms.

(4) Mrs. N. B. Age 38. **Operation:** January 15, 1920. Excision cyst left Bartholin's gland. Double salpingo-oöphorectomy. Resection fundus uterus. Freeing of adhesions, appendectomy, autotransplant of ovary into abdominal wall. **Pathology:** Bilateral tubo-ovarian masses and fundus adherent to omentum and sigmoid. Ovaries enlarged, cystic degeneration marked. Tubes distended, fimbriated ends sealed, hydrosalpinx. Left tube and ovary densely adherent in cul-de-sac. Much raw surface on fundus due to adhesions. Resection below attachment of round ligament. Reimplantation of round ligament.

Autotransplant size end of index finger from right ovary. Transplant into pocket between peritoneum and under surface left rectus muscle.

January 28, 1920. Wound healed primary union. Examination October 12, 1920: First menstruation nine weeks after operation. Scanty flow, no pain. Three days' duration. About two weeks before menstruation began she had moderate hot flushes and some dizziness which disappeared at onset of period. Has had regular monthly periods since operation with the exception of the August period, which was missed entirely. During this

time the ablation symptoms were somewhat more severe than at any time since operation.

As a rule she menstruates seven days, scanty first two days, moderate the other five days. No pain. Abdominal wall slightly sensitive during menstruation. At present has only occasional flushing and very slight. Thinks that she is not more nervous than before operation.

Vaginal Examination: Shows small uterus, somewhat adherent, not painful. No masses or tenderness in right and left pelvic regions. Graft in abdominal wall not palpable. Patient also stated that while in hospital she was troubled with nightly amorous dreams and she is now more passionate than she has been for years.

(5) Mrs. D. C. Age 20. Admitted S. F. H. August 7, 1919. Diagnosis: Bilateral salpingitis, chronic. Cervicitis, chronic. Discharged improved. Re-admitted October 8, 1919. Diagnosis: Bilateral salpingitis, chronic. Urethitis, acute. Erosion of cevix. Re-admitted December 5, 1919. Diagnosis: Salpingo - oöphoritis bilateral, subacute. Endocervicitis. Erosion of cervix. **Operation:** January 20, 1920. Curetage, cauterization of cervix, double salpingo - oöphorectomy, appendectomy, ovarian transplant into left cornua of uterus. Transplant from left ovary, 2x1x½ cm. **Pathology:** Both tubes and ovaries surrounded by light adhesions and bound down to posterior surface of broad ligament and sigmoid. Both tubes thickened, friable and fimbriated ends sealed. Ovaries enlarged, moderately cystic, size of large walnuts and after being freed showed large areas of raw surface, and it was considered advisable to remove them to prevent adhesions and further cystic degeneration. Uterus normal size and position, body firm, very few raw areas, which were closed. Decided to leave uterus and section of left ovary 2 cm. by 1 cm. transplanted in left cornua of uterus.

Unable to trace patient, so cannot give results.

(6) Mrs. G. L. Age 20. **Operation:** March 20, 1920. Deep cauterization of cervix. Double salpingo-oöphorectomy. Supra-vaginal hysterectomy. Freeing of adhesions, autotransplants. **Pathology:** Dense adhesions of omentum and sigmoid to double tubo-ovarian masses and fundus and posterior surface of uterus. Both tubes and ovaries adherent to posterior surface of uterus. Double pyosalpinx. Ovaries size of large walnuts, cystic and seat of inflammatory disease. Uterus larger and softer than normal. Uterus too badly involved by adhesions and metritis to leave. One section 2x1 cm. taken from each ovary and transplanted into subcutaneous fat on either side of incision.

April 1, 1920. Wound healed, primary union.

June 15. Severe flushes since three weeks after operation. Says she is more nervous. Grafts palpable but smaller than at operation.

August 10, 1920. Grafts larger than previously, moderately tender, began enlarging about one week ago. No flushes or nervousness for past ten days. Feels fine.

October 2, 1920. Grafts seem to enlarge and become tender about once a month. During this time the patient feels much better than during the intervals when grafts are small. Has much less flushing and nervousness but is never entirely quite free from these symptoms.

(7) Mrs. E. S. Age 30. **Operation:** June 17, 1920. Curetage, anterior colporrhaphy, perineorrhaphy, double salpingo-oöphorectomy, appendectomy, freeing of adhesions. Autotransplantations both ovaries into abdominal wall. **Pathology:** Both ovaries and tubes adherent in cul-de-sac by firm adhesions. Lumen of tubes closed. Both ovaries equally cystic. Corpus luteum cysts. Appendix adherent to right tubo-ovarian mass. Uterus normal size and position, not adherent. Apparently healthy and not removed. Autotransplants from both ovaries 2x2x1 cm. One transplant on either side of abdominal wound in subcutaneous tissue.

June 20, 1920. Slight separation at upper end and middle section of wound. No serum or purulent discharge. Closed with adhesive plaster.

July 6, 1920. Wound closed. Grafts palpable. No tenderness.

October 1, 1920. No flushing, palpitation or nervous phenomena since operation. First menstruation July 26, scanty, lasted for four days, used one pad a day. Grafts not tender. Second menstruation, August 18, menstruated for five days, good flow. Stopped for one day, then menstruated slightly for two days, soreness in either side of wound.

September 19, 1920. Flowed five days, heavy flow, no discomfort. Noticed a peculiar feeling in region of grafts for three days after menstruation had stopped. Patient states that periods are now more regular and that she had less discomfort than at any time since she can remember. Previously periods were very irregular, amenorrhea varying from three to nine months. Patient volunteered that she had feared loss of sexual desire after the operation, but such has not been the case. Is now the same weight as when in the best of health.

Pelvic Examination: Uterus normal size and position, not tender, movable. Pelvis free, no tenderness. Grafts palpable, not tender.

(8) Mrs. J. T. Age 41. **Operation:** July 22, 1920. Dilatation, curetage, double salpingo-oöphorectomy, appendectomy. **Pathology:** Both tubes enlarged, ends sealed, tubes distended with clear fluid. Left ovary size plum, marked cystic degeneration, densely adherent to posterior surface left broad ligament and pelvic wall. Right ovary adherent, normal size, cystic degeneration moderate. Uterus normal size and position, very few adhesions to uterus, hence not removed. Appendix retrocecal, adherent, removed.

Right ovary placed in normal saline solution, temperature 100°. Three sections of right ovary 2x½ cm. placed in pockets made in subcutaneous tissue 3 cm. to right and left of incision. Two transplants made on left side, one on right side.

August 2, 1920. Wound healed, primary union. Grafts palpable, not tender.

August 28, 1920. Grafts larger than previously, slightly tender. Has had few slight flushes, slightly more nervous. Is regular time for menstruation. Thinks that there is slight thin white discharge from vagina.

September 6, 1920. Grafts smaller than last week, not tender. Less nervous, no flushes. Feels fine, gained seven pounds in weight.

October 7, 1920. Grafts somewhat enlarged and sensitive about the end of the month. Patient notices a periodicity in the change in the grafts. States that they enlarged once a month and about the time that she used to menstruate before the operation. Four days after grafts enlarged this last time she had a slight flow for one day only. No pain or pelvic discomfort. One month previous to this time she felt as though she was going to menstruate but had only a thin, white vaginal discharge. States that the "hot spells," nervousness and slight dizziness that she noticed after the operation are much less.

(9) Mrs. C. B. L. Age 34. **Operation:** August 3, 1920. Dilatation and curetage. Supravaginal hysterectomy, bilateral salpingo-oöphorectomy, appendectomy. **Pathology:** Uterus retroverted and bound down to rectum by dense adhesions to tubes and ovaries bound down by adhesions to cul-de-sac. Uterus larger and softer than normal. Bilateral pyosalpinx and cystic degeneration of ovaries. Ovaries badly lacerated during removal. Autotransplants of piece of each ovary 2x2x1 cm. into subcutaneous fat.

Convalescence normal. Wound healed, primary union.

October 9, 1920. Grafts palpable, not tender. Three weeks after operation had flushes of heat, not severe. Patient somewhat more nervous since operation. Has noticed no change in size of grafts. Flushes remain about same and do not inconvenience patient. Has been working hard and thinks some of nervousness due to that.

(10) Mrs. C. B. Age 27. **Operation:** August 18, 1920. Curetage, cauterization of cervix double salpingo-oophorectomy. Denudation of sigmoid repaired by omental grafts. Appendectomy. Subcutaneous ovarian transplants, two in left and one in right side of incision. **Pathology:** Sigmoid adherent to left tubo-ovarian mass size of an apple, peritoneal coat of sigmoid torn in several places during separation. Left tubo-ovarian abscess. Right pyosalpinx, right ovary adherent to tube and pelvic wall and appendix. Ovary badly traumatized and surface denuded. Fundus of uterus resected down to attachment of round ligaments. Right ovary removed because of damage to blood supply and extensive denudation of surface. Such an ovary would have become painful, adherent and cystic. Three grafts 2x2x1 cm. transplanted into subcutaneous tissue.

October 12, 1920. Moderate ablation symptoms began five weeks after operation. No menstruation to date. Grafts palpable, no change in size, not tender.

March 26, 1921. Wound became sensitive in region of grafts about end of December. Again became sensitive in second week of January and five days later had slight flow for one day. Since January flows regularly for three days, moderate amount and has no pain. Moderate flushing was present for four months after operation. Now free for as long as two months at a time and is only occasional and slight.

Pelvic Examination: Uterus normal size, slightly pulled to left, not tender. Pelvis is negative, no palpable enlargement of grafts, but slight tenderness of wound.

OVARIAN AUTOTRANSPLANTATION WITHOUT HYSTERECTOMY

No.	First Menstruation Post Operation	Ablation Symptoms	Condition of Grafts
1.	4½ months after operation. Now regular. No pain.	Severe up to menstruation. Now decreased and mild.	Grafts not palpable, but slight tenderness of wound before and during menstruation. Uterus normal size and position, freely movable, no tenderness or pelvic masses. Increased sexual desire.
3.	6 months after operation. Now regular, no pain. 1½ days.	Moderate flushes for first 7 months. Now entirely free.	Grafts palpable. Slightly tender. Enlarge one week before menstruation.
4.	9 weeks. Scanty at first. Now regular. 7 days. No pain.	Moderate flushes and nervousness for 3 months. Now only occasional and slight.	Uterus small, somewhat adherent. No pelvic masses or tenderness. Sexually stronger than for years.
5.	Unable to trace patient.		
7.	5 weeks, scanty at first. Now regular, 5 days' heavy flow, no pain.	No ablation symptoms since operation.	Grafts not palpable. Has peculiar feeling in region of grafts during menstruation. Uterus normal size and position, movable, no masses or tenderness.
8.	3 months scanty, 1 day. No pain.	Moderate symptoms after operation. Less now.	Monthly enlargement and tenderness of grafts.
10.	5 months, scanty at first. Now 3 days, moderate flow. No Pain.	Moderate symptoms for 4 months after operation. Now free for as long as 2 months at a time. Symptoms only occasional and slight.	Uterus normal size, slightly pulled to left. Not tender, pelvis negative. No palpable enlargement, but slight tenderness of wound.

OVARIAN AUTOTRANSPLANTATION WITH HYSTERECTOMY

No.	Ablation Symptoms	Enlargement and Tenderness of Grafts
2.	Began 6 weeks after operation. When grafts are small she has severe flushing and nervousness. When grafts are enlarged she has slight symptoms and is much more energetic and feels fine.	Grafts palpable. Enlarge at irregular intervals. Grafts slightly tender.
6.	Moderate flushing and nervousness began 3 weeks after operation. Ablation symptoms very much tempered by enlargement of grafts, but never entirely free.	Enlargement and tenderness of grafts monthly.
9.	Flushing began between 3 and 4 weeks after operation. Now only slight and do not inconvenience patient.	Grafts palpable, but do not change in size.

(120 Flood Building)

CHRONIC TUBERCULOSIS IN EARLY INFANCY*

By RACHEL L. ASH, M. D., San Francisco, Cal.

Tuberculosis occurs at all ages and under all social conditions. Its unsuspected frequency in adult life became known with the publication of the post-mortem statistics of Naegeli[1] in 1900 and Burkhardt[2] in 1906. More recently the tuberculin reaction, the X-ray and careful clinical study have made available the statistics of childhood and more especially those of infancy. Tuberculosis of infancy generally runs a rapid course to a fatal termination and the younger the infant the shorter the duration of the disease.

Sometime ago a tuberculous infant came under observation at the University of California Hospital whose disease ran so chronic a course that the correct diagnosis was not made until a few months before death. As this case presents valuable material for study it will first be reported briefly and then its most important aspects will be discussed in relation to the tuberculosis of early infancy.

C. N. (U. C. H. No. 17062) aet 6 months, was brought to the hospital April 9, 1918, for difficulty in breathing. Here she remained until her death, November 16, 1919, at the age of two years and one month. The mother, who died of pulmonary tuberculosis when the infant was four months old, had nursed her for the first six weeks of her life; then the child was removed from the home environment. At six months her gain over her birth weight was four pounds only. A questionable history of syphilis was obtained from the father, who, on examination, however, showed no signs nor stigmata of lues; his Wassermann was negative.

The most distressing feature of this pale, poorly nourished, irritable little baby was dyspnoea; the expiration was accompanied by a sharp, apparently painful, little cry or cough. The markedly emphysematous chest displayed an unusual prominence of the upper sternum. Movement was slight at the bases, especially at the right. The skin was mottled with a fine papular rash over the scalp, neck and back. A general glandular adenopathy was present, the glands being aggregated into small masses in the cervical and inguinal regions. Percussion of the chest elicited sub-manubrial dullness, interscapular dullness, and slight dullness over the lower right lung posteriorly. Large snoring and small bubbling and crepitant rales were heard generally over the pulmonary area. D'Espine was positive to D₆. The heart and the abdomen showed nothing unusual. The temperature ranged from 36.5° to 39°, the respirations occasionally reached 55°. The skin and intra-dermal tuberculin tests and the Wassermann reactions were negative. Repeated blood counts and examinations of the urine developed nothing of importance. The diagnosis of enlarged thymus, enlarged root glands and tuberculosis of the lungs was borne out by the X-ray findings. The respiratory difficulty was thought at this time to be due to hypertrophy of the thymus. No definite opinion was given as to the character of the rash.

For some months the child's general condition remained the same apparently; the pulmonary process developed very slowly but gradually reached the other lung. Transitory attacks of pneumonia seemed not to hasten the course of the disease. When the child had been in the hospital six months a painful swelling appeared about the left elbow joint. From this time on the involvement of the osseous system became the dominant feature. There followed in succession the disease of the right radius, the right, the left tibia, metatarsals, some of the metacarpals, both ankle joints, an otitis media, the nasal bones and finally the right mastoid.

The radiological diagnosis was persistently syphilis of each long bone as it was submitted, while the diagnosis of the lung plates oscillated between syphilis and tuberculosis. The Wassermann and tuberculin tests remained negative, and anti-luetic treatment was without result.

Eventually one of the ankle joints became fluctuant; it was curetted and the pathologic and the bacteriologic reports were tuberculosis. The Von Pirquet became positive when the child was two years old, and about the time that it became necessary to operate for a staphylococcus aureus mastoid infection, secondary to the long-standing otitis media. A low-grade staphylococcus septicemia followed and the patient died suddenly one month after the operation.

AUTOPSY DIAGNOSIS (DR. G. Y. RUSK)

Chronic pulmonary tuberculosis with cavity formation in left upper and right middle and lower lobes, with a diffuse distribution of conglomerate tubercles throughout the remainder of the lung. Bilateral chronic adhesive pleurisy. Bilateral cervical adenitis. Acute and chronic tuberculous ulcers of ileum. Caseous mediastinal and mesenteric lymph nodes. Isolated conglomerate tubercle of the left kidney. Tuberculous osteomyelitis of right tibia and fibula. Tuberculosis of the tarsal bones of right foot with sinus formation. Tuberculous necrosis of lower end of humerus and upper end of radius and ulna with involvement of the joint. Marked emaciation.

A more detailed description of the lungs and bones follows.

Left Lung—The pleural surface is covered with fibrinous adhesive tags. On palpation the upper lobe feels perfectly solid and nodular solid areas can be felt in the lower lobe. On section there are found several cavities in the upper lobe. The largest one measures 2 cm. in diameter. These cavities are surrounded by *thick indurated white walls*. The lower lobe contains mutiple conglomerate tubercles, some of which are caseous. The intervening lung tissue shows marked hypostatic congestion. Some areas are very suggestive of broncho-pneumonia.

Right Lung—The pleural surface is covered with fibrous tags of adhesions. Solid and nodular masses can be palpated in the upper lobe. On section the upper lobe shows several conglomerate tubercles; the intervening lung tissue is rather

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

emphysematous. The middle lobe contains a cavity 1.5 cm. in diameter, the wall of this cavity is ragged and is surrounded by a *wide zone of fibrosis*. The lower lobe contains several cavities, the largest one measures 2 cm. in diameter. These cavities with *their nodular fibrous walls* occupy practically the entire lower lobe.

Upper Extremities—The left elbow is fixed in a position of semi-flexion exposing the joint. The lower end of the humerus is necrotic and caseous; the upper end of the radius and ulna also shows necrosis of the bone. The joint is involved with fibrous ankylosis and tuberculous granulation tissue covers the articular surface. The soft tissues around the joints are indurated and edematous. There is no sinus formation.

Lower Extremities—The entire tibia and fibula of the right side were removed. The periosteal surface of the tibia is slightly roughened. On section the marrow of the tibia is firm and caseous in appearance. The lower end of the marrow canal in this region is surrounded by a very thin shell of bone. The bony shaft is rather thin throughout the extent of the tibia but there are no points of necrosis.

The fibula is somewhat distorted in shape and surface is irregular. The marrow at a point about the center of the bone appears caseous. Over the dorsum of the foot 4 cm. below ankle joint there is an opening surrounded by indurated granulation tissue.

On exposing the tarsal bones they appear soft and osteoporotic but no definite necrosis can be made out.

The brain was removed. There was a moderate increase in the amount of cerebrospinal fluid. The brain was apparently normal.

SOURCE OF INFECTION

Tuberculosis of the earliest weeks of life is either congenital or acquired. By congenital tuberculosis is meant a direct transference of tubercle bacilli from the mother to the child in utero, either by the circulating blood—the placental route, or by the aspiration or deglutition of tuberculous amniotic fluid. Von Reuss[3] collected 26 indisputable cases of congenital tuberculosis from the literature; the children were either born prematurely or lived a few weeks, and the primary foci of infection were found in the lymph nodes about the portal vein, the liver and spleen. Acquired tuberculosis is a post-natal invasion through the usual external portals of entry; the duration of life is usually longer. The case above was undoubtedly acquired tuberculosis, as shown by early signs within the chest, the chronicity of the infection and the history of direct contact with maternal pulmonary tuberculosis.

THE COURSE OF THE INFECTION

If we accept the pathological and clinical evidence that the lungs presented the oldest lesions, the course of the infection can be satisfactorily followed. Very early in life, tuberculous material, aspirated by the infant, lodged in some alveolus—the primary lung focus (Ghon's[4] primäre Lungenherd). There may have been several such early foci during the six weeks of maternal contact. Soon the regional and later the peri-bronchial and peri-tracheal glands became involved. When the child came under observation, the glandular hyperplasia had already become massive in a valiant but futile attempt to localize the process. Many areas of consolidation were already present, especially in the right lung, the sequel of a ruptured caseous gland or of a new infection from an extraneous source. The disease of the bones was of a much later date, due probably to haematogenous invasion from distant foci. Still later gastro-intestinal lesions appeared. The pulmonary disease can not be classified with the usual tuberculosis of these organs in infancy. The postmortem report reads: "The wall of the cavity is surrounded by a wide wall of fibrosis. These cavities are surrounded by thick indurated white walls." Pulmonary tuberculosis at this period of life runs its course quickly. In all of Ghon's 27 cases with cavity formation in the first two years of life, an early dissemination of miliary tubercles occurred. Delicate attempts at healing were observed in only three cases. Geipel[5] thus describes the cavities of early infancy: "An encapsulating tissue reaction does not develop in the periphery, at least not noticeably. A caseous pneumonic zone surrounds the cavities which later may coalesce." It would seem that this child had been so vaccinated "by a first infection by way of the lungs" (Opie[6]) or had become so allergic (Von Pirquet[7]) that a second infection assumed a chronic character.

CLINICAL OBSERVATIONS

Only the clinically important features will here be discussed. The expiratory dyspnœa and stridor and the accompanying cough were so remarkably pathognomonic that had it not been for the enlarged thymus an immediate diagnosis of compression due to tuberculous peri-tracheal and peri-bronchial glands would have been made. This respiratory difficulty disappeared toward the end of the first year. The skin condition was probably tuberculosis, but was not so diagnosed. It is said that only 17 per cent of all tuberculides are diagnosed correctly. Figures show that they occur in about 20 per cent of all cases of infantile tuberculosis. The lungs were always suggestive of tuberculosis, although no cavities could be demonstrated and the constancy of the percultatory and auscultatory phenomena were puzzling. The greatest diversity of opinion ranged about the X-rays of the bones. From the radiographer's standpoint these were undoubtedly syphilis, as shown by location of the primary foci, the periosteal thickening, the bone proliferation accompanying bone destruction, and the absence of sinus formation. The presence of tuberculosis need not exclude lues; but here the postmortem reports did exclude it. Since this case was studied, three other cases of bone tuberculosis with a radiographic diagnosis of syphilis have come under observation, in somewhat older children, however. Two died of meningitis tuberculosa, and the third, a patient of Dr. Langley Porter, developed skin tuberculides confirmed by pathologic section.

The tuberculin reaction was also unusual. Why it appeared late or why it appeared at all it is impossible to say. According to Dunn and Cohen,[8]

who studied 374 cases with 138 necropsies, the positive Von Pirquet has a great diagnostic value, "but the presence of a negative Von Pirquet in no way rules out the diagnosis in a child under two years of age."

DURATION AND PROGNOSIS

The duration of tuberculosis acquired during the first year of life is very short, but few infants reach the fifteenth month. Dunn [8] and Fischberg,[9] however, believe that if the condition remains primary—that is, with the Von Pirquet, the sign of D'Espine and the roentgenogram—any one or all of these as the only signs of tuberculosis—calcification and cicatrization may occur. As evidence they have autopsies of infants who have died of intercurrent diseases. Schlossmann [10] holds that in tubreculoscis of infancy there is no trend toward calcification. "Indeed there is not a positive instance where a tendency toward limitation of the disease was observed." Geipel [5] believes that the mortality is 100 per cent. It would seem then, that the duration of the disease depends on the infant's native defense, the number of primary foci, and the virulence of the infecting organism. And as, in the first months of life there is rarely any attempt toward the latent inactive state of later life, the prognosis is bad.

The above case is reported because in the opinion of the many clinicians who observed its progress, it was an unusual example of the adult type of tuberculosis occurring in infancy.

NOTICES

The University of California Medical School has received notification that Dr. C. v. Pirquet has been obliged to forego his western trip and that his lecture engagements are therefore cancelled.

Important—

CONVENTION PROGRAM will be closed and go to press the first week in February.

NEPHRECTOMY IN HUNCHBACKS—WITH REPORT OF TWO CASES

By CHAS. D. LOCKWOOD, M. D., Pasadena

Surgeons who have preformed nephrectomy on the hunchbacked will, I am sure, testify to the extreme difficulty attending this operation in patients suffering with this deformity. It has been my duty to operate two such cases and the difficulties encountered in technique, as well as the unusually interesting features characterizing both cases, seemed sufficient justification for this paper.

Not only is the ordinary technique of lumbar nephrectomy quite impossible in these cases, but there are grave difficulties accompanying the abdominal route. In persons suffering with kyphosis the lower ribs overlap the crest of the ileum and the intercostal spaces are so narrowed that no room is left for adequate exposure of the kidney. The abdominal route, which presents the only feasible approach, is also greatly complicated by the deformity. The antero posterior diameter of the abdominal cavity is greatly deepened and there is a corresponding shortening of the longitudinal diameter. The kidney is carried well up into the concavity opposite the kyphosis and this renders it quite inaccessible.

The great shortening of the longitudinal diameter of the abdominal wall renders the ordinary rectus incision inadequate. If the incision is carried farther out, the overhanging ribs and the crest of the ileum so encroach upon the available space as to render such an incision useless. These difficulties are best met by a combined outer rectus incision and a transverse incision following the lower border of the ribs as far out as possible. The overhanging ribs are then lifted upward by broad powerful retractors. The retroperitoneum is now slit, the ureter ligated and the kidney dislocated toward the medium line. The renal vessels are next clamped and divided. Especial difficulty is encountered in ligating the vessels, inasmuch as this step in the operation, as well as the others, is done almost entirely by touch. If drainage is indicated it is best secured by means of a stab wound retroperitoneally between the ribs.

CASE REPORTS

Case I.—C. A. St. A. Age 52. Occupation, barber. Family history, good; both parents lived to be over seventy-five years of age. Habits good. No venereal infection. At age of thirty developed Pot's disease of the spine. He was treated by Dr. Gillette of St. Paul, and his spine lesion healed, leaving a marked kyphosis.

His chief complaint was frequent and painful urination. Once or twice he had noticed a little blood in his urine. He was conscious of his left side, especially if he caught cold. It was heavy and painful at times.

Examination: Anemic-looking, hunchbacked. Chest negative except for deformity. Abdomen negative. Per rectum, hard slightly movable insensitive prostate. Number fifteen Franch catheter passed without difficulty. Two ounces of cloudy urine withdrawn. Circulation fair. Blood pressure, 140. Cystoscopic examination: Two attempts were made to catheterize the ureters, but owing to great deformity and sensitiveness of the bladder, they were unsuccessful. A good view, however, was obtained of both ureteral orifices. The left orifice was oedematous and ulcerated; the right, normal except for slight relaxation and pouting. Left nephrectomy was determined upon. The

urine contained many tubercule bacilli. Operation: A left rectus incision was made, and this was joined by a transverse one along the lower border of the ribs. The kidney was small, densely adherent to its capsule and very inaccessible. Considerable difficulty was encountered in securing the pedicle, and bleeding was quite free. The patient left the table in good condition.

Post-operative course: Acute nephritis developed on the third or fourth day, with high temperature. The patient eliminated fifteen to thirty ounces of urine daily. The blood showed nitrogen retention. He was placed on a carefully measured diet, consisting entirely of carbohydrates. He gradually improved, wound healed and did not subsequently break down, although there was wound infection. Two months after operation, the patient suddenly died one night. No autopsy was allowed. The kidney when removed showed little gross trouble, but there were one or two suspicious areas. A glass slide drawn over these areas and stained, showed tubercle bacilli in abundance.

Case II.—Mr. G. P. Age 79. Retired manufacturer. First seen November 21, 1919. Family history negative. Habits good. Venereal history negative.

Present complaint: One month prior to my examination he had an attack of hematuria. This recurred and he was passing blood freely from the urethra. At times it was bright red, and at times mixed with urine. He arose several times at night to urinate. He suffered no pain. He was very nervous and much afraid of surgery.

Physical examination: Vigorous-looking old man of Danish descent. Chest, barrel-shaped as a result of marked kyphosis. This was congenital in origin, and not tubercular. Abdomen, retracted and shortened, with eleventh and twelfth ribs overlapping the ilium. Per rectum, large, soft, movable prostate.

Cystoscopic examination: November 24, 1919, patient was so frightened and nervous that a satisfactory examination was impossible. There was free hemorrhage, which seemed to come from an intravesical lobe of the prostate. The ureters could not be found, owing to their situation behind the greatly enlarged lateral lobes and the bloody field. There were two ounces of residual urine. The hemorrhage was thought to come from the prostate gland, and prostatectomy was advised. The bleeding stopped after a few days' bladder drainage with an inlying catheter. Patient refused operation, and returned home.

Hemorrhage soon recurred and two months later, January 23, 1920, a supra-public prostatectomy was performed. A moderately large prostate with large intravesical lobes was removed. The bladder seemed normal to palpation and inspection. Patient stood operation well, but suffered considerable post-operative shock, owing to his anemic condition. There was no hemorrhage following operation until the end of the sixth week. When the wound was closed and patient was about to leave the hospital, he began to pass bloody urine similar to that passed before his prostate was removed.

Cystoscopic examination revealed a villous growth near the right meatus, which was thought to be the source of hemorrhage and which had been overlooked at operation. The supra-pubic wound was reopened and villous tumor cauterized. All bleeding stopped. Wound healed, and patient again passed his urine normally and returned home. Within a few weeks, bleeding recurred and continued at intervals for six months. After three unsuccessful attempts by Dr. Ferrier, my associate, and myself to catheterize the ureters, Dr. Ferrier succeeded in securing a good view of both ureters. Clots of blood were protruding from the left ureter, the right spurted clear urine. Pthalein appeared on the right side in three minutes, and the thirty-minute percentage was 18 per cent. Four per cent dye was excreted from the left side.

Left pyelogram (described by Dr. Ferrier): 10 cc. of 20 per cent sodium bromide injected without spasm. Normal kidney position. Pelvis moderately enlarged with a smooth outline. Projecting into the pelvis from the renal parenchyma is a round, smooth filling defect, 2.5 in diameter. No distortion or retraction of the calyces.

A diagnosis of tumor projecting into the kidney pelvis was made, probably a papiloma. Filling defect due to blood clot was excluded because of the low comparative function, the fact that the shadow was continuous with the renal papillae and was not observed at the pelvic outlet, while the pelvis was definitely enlarged.

The patient had become almost exsanguinated and his hemoglobin ran down to 30 per cent. He was transfused six or seven times at short intervals with great improvement.

Finally on June 12, 1920, his left kidney was removed through a left rectus incision, by the technique described above. While closing the wound, he was again transfused. He made a prompt and complete recovery and is now in good health.

The tumor proved to be an adeno-carcinoma of the cortex of the kidney and a papilloma of the upper calyx which projected into the kidney pelvis.

ETIOLOGY OF GOUT

By W. F. McNUTT, SR., M. D., San Francisco

The etiology of few diseases has been more discussed than has gout. Very few writers have frankly admitted the fact that the cause is unknown. Sydenham said, "No very limited theory and no one particular hypothesis can be found applicable to explain the whole nature of gout." Trousseau wisely did not attempt, as most writers did and do, to define and explain the cause of gout. He said, "It is dominated by a specific cause, which we know only by its effects and which we term the gouty diathesis." Osler states that "Alcohol is the most potent factor in the disease (gout). There is probably defective oxivation of the foodstuff, combined with imperfect elimination of the waste products of the body." But frankly states, "The nature of gout is unknown."

Most writers who proceed to explain their particular theory of gout would, no doubt, subscribe to Shakespeare's wisdom when he makes Hamlet say, "There are more things in heaven and earth, Horatio, than are dreamt of in your philosophy." Only a few years ago, it might be called medical heresy to doubt that uric acid in the blood was not the cause of gout. I can well remember when Chalmers Watson apologetically hinted that uric acid might not be the sole cause of gout. He said, "It would, I think, be well if much less attention were centered on the excretion of uric acid alone, as the all-important factor of the disease"—gout. Uric acid in the blood has been abandoned as the cause of gout. It would, no doubt, be called medical heresy at present to doubt that a local foci of infection is the cause of gout. The foci of infection may be at the

Note—Members of the medical profession undoubtedly will derive inspiration from this article by a member of our profession who has been in active practice for sixty years, and who is still actively interested in the welfare of the sick.—Editor.

root of a tooth, or in the tonsils, or any other place.

We do know that we have hereditary and so-called acquired gout. Acquired gout is the development of gout, by food, habits, etc., only when there is a gouty diathesis. We know that age, occupation, clothing, diet habits, etc., are potent factors that make for gout. Those of us who have practiced medicine for many years, know that many persons overeat, drink freely, live an irregular and dissolute life, often not a sound tooth in their mouth, and no gout because there was no gouty diathesis. My own experience and belief is, that it is not red or dark meat, or duck or turkey protein food, or strawberries, etc., or the quality, but the quantity of food, drink, etc., that makes for gout. Those who eat and drink sparingly, live a careful, well regulated life, may often avoid hereditary gout and will surely avoid acquired gout.

When the etiology of a disease is unknown, it behooves the physician to be wary in prescribing or proscribing certain articles of food. He must be guided by clinical experience. And here, again, the physician should be particularly on his guard who depends upon clinical experience. The influence of the mind on the body, especially the sick body, is such that the physician is often honestly deceived in ascribable cures to his remedies, and draws erroneous conclusions as to the cause of the disease. For instance, before we knew anything of the etiology of phthisis, how many theories of its etiology and cures were advocated and believed. It would be appalling, if we could only know the number of stomachs that have been injured by bicarbonate of soda and the prolonged use of alkaline mineral water to neutralize the uric acid in the blood of gouty people. Some physicians learn by years of experience that to be conservatively progressive is wisdom.

An old Scotch physician listened very attentively to a young physician's enthusiastic account of a discovery of a new remedy with which he had cured three patients, thought to be incurable. The young physician was very anxious for his senior to adopt the new remedy. The old physician said, "I'll jest bide-a-wee tie you cure more patients." The etiology of gout will be discovered some time. It may be that the time will come when gout will only remain as a memory—as a disease that was and is not. Who knows?

Gout would seem to be a disease of many relations, judging from the term in use. We speak of rheumatic gout, gouty arthritis, gouty phlebitis, gouty critis, gouty nephritis, gouty bronchitis, gouty asthma, etc. May I not say, while the etiology of gout is unknown, it behooves us to rely on empirical remedies, established by clinical experience, combined with the treatment of the patient. Is there any relation of gout to pernicious anemia? Has every case of pernicious anemia a gouty diathesis?

GENERAL SESSION AND SECTION OFFICERS FOR THE 1922 MEETING OF THE STATE SOCIETY

The list of the officers of the general sessions and the various sections of the State Society is published below, so that members desiring to contribute papers may have the names and addresses of the proper officers of the section in which they are interested. Members desiring to present papers should communicate without delay with the chairman and secretary of the appropriate section, because the program is getting well under way and will be closed and go to press the first week in February.

The Secretary of the State Society, as chairman of the General Program Committee, invites correspondence and suggestions regarding any phase of the 1922 program.

GENERAL SESSIONS

Chairman, Dr. John H. Graves, President of the Society, 977 Valencia Street, San Francisco.
Secretary, Dr. W. E. Musgrave, Chairman of the Program Committee, 912 Butler Building, San Francisco.

SECTION ON TECHNICAL SPECIALTIES

Chairman, Dr. Ray Lyman Wilbur, President Stanford University.
Secretary, Dr. Charles T. Sturgeon, Merritt Building, Los Angeles.

SECTION ON MEDICAL ECONOMICS, EDUCATION AND PUBLIC HEALTH
(League for the Conservation of Public Health)

Chairman, Dr. Dudley Smith (President League for the Conservation of Public Health), Thomson Building, Oakland.
Secretary, Dr. W. T. McArthur (Secretary League for the Conservation of Public Health), Security Building, Los Angeles.

SECTION ON INDUSTRIAL MEDICINE AND SURGERY

Chairman, Dr. E. W. Cleary, 177 Post Street, San Francisco.
Secretary, Dr. Packard Thurber, 906 Black Building, Los Angeles.

SECTION ON RADIOLOGY
(Roentgenology and Radium Therapy)

Chairman, Dr. Albert Soiland, 527 West Seventh Street, Los Angeles.
Secretary, Dr. H. E. Ruggles, Butler Building, San Francisco.

SECTION ON PATHOLOGY AND BACTERIOLOGY

Chairman, Dr. William Ophuls, Stanford University Medical School, San Francisco.
Secretary, Dr. Roy W. Hammack, Brockman Building, Los Angeles.

SECTION ON GENERAL MEDICINE

Chairman, Dr. Joseph M. King, Brockman Building, Los Angeles.
Secretary, Dr. E. S. Kilgore, 391 Sutter Street, San Francisco.

SECTION ON PEDIATRICS

Chairman, Dr. William Palmer Lucas, University Hospital, San Francisco.
Secretary, Dr. Hugh K. Berkley, Brockman Building, Los Angeles.

SECTION ON NEUROPSYCHIATRY

Chairman, Dr. Walter F. Schaller, 909 Hyde Street, San Francisco.
Secretary, Dr. W. B. Kern, Brockman Building, Los Angeles.

SECTION ON GENERAL SURGERY

Chairman, Dr. Charles D. Lockwood, 295 Markham Place, Pasadena.
Secretary, Dr. Edmund Butler, Butler Building, San Francisco.

SECTION ON EYE, EAR, NOSE AND THROAT

Chairman, Dr. Frank A. Burton, Watts Building, San Diego.
Secretary, Dr. Harvard McNaught, Butler Building, San Francisco.

SECTION ON UROLOGY

Chairman, Dr. George W. Hartman, 999 Sutter Street, San Francisco.
Secretary, Dr. Louis Clive Jacobs, 462 Flood Building, San Francisco.

SECTION ON ORTHOPEDIC SURGERY

Chairman, Dr. W. W. Richardson, Brockman Building, Los Angeles.
Secretary, Dr. G. J. McChesney, Flood Building, San Francisco.

SECTION ON ANESTHESIOLOGY

Chairman, Dr. Mary E. Botsford, 807 Francisco Street, San Francisco.
Secretary, Dr. Eleanor Seymour, 308 Consolidated Realty Building, Los Angeles.

SECTION ON GYNECOLOGY AND OBSTETRICS

Chairman, Dr. Harry M. Voorhees, Brockman Building, Los Angeles.
Secretary, Dr. L. A. Emge, Stanford University Hospital, San Francisco.

Pharmacy and Chemistry

Edited by FELIX LENGFELD, Ph. D.

Help the propaganda for reform by prescribing official preparations. The committees of the U. S. P. and N. F. are chosen from the very best therapeutists, pharmacologists, pharmacognosists and pharmacists. The formulae are carefully worked out and the products tested in scientifically equipped laboratories under the very best conditions. Is it not plausible to assume that these preparations are, at least, as good as those evolved with far inferior facilities by the mercenary nostrum maker who claims all the law will allow?

Patent Medicines in England.—We continually hear from hyphenated and semi-hyphenated Americans how much better things are done abroad than in this country. It is refreshing, therefore, to learn that some things are not so well done. England seems to be at least fifteen years behind us in the matter of regulating patent medicines. Apparently any nostrum may be foisted upon the unsuspecting public and any claim made, no matter how preposterous or dangerous.

Pil Mixed Treatment (Chichester), sold in the form of pills containing 1/20 grain mercuric iodid and 5 grains potassium iodid, has been extensively advertised as a standard routine treatment for syphilis, but has been refused admission to the N. N. R. because an examination made in 1907 showed that the claims were unwarranted, exaggerated and misleading.

"If heeded by those who read the advertising it will result in much harm to the public and the profession. For this reason the present report of the Council is published as a protest against any advertising propaganda advocating the routine treatment of a disease which requires that each case be studied carefully so that prompt and efficient measures may be applied to the various manifestations of the disease." (Jour. A. M. A., Oct. 22, 1921, p. 1355.)

The paragraph quoted should be put into permanent form and a copy sent to every physician, for it applies not alone to this preparation but to many others on the market. Every patient certainly has a right to ask that the physician consider his case by itself and prescribe for his case and his case alone, by using such remedies and such quantities as seem indicated and only using a proprietary preparation when it just happens to fit the individual case.

Endocrinology and Pseudo-Endocrinology.—R. G. Hoskins, Professor of Physiology, Ohio State University College of Medicine, pleads for a greater degree of discrimination on the part of physicians in evaluating not only proper data, but also the various agencies either seeking support in or exploiting this field. The latter aspect of the situation deserves special emphasis. Those who purpose acting as purveyors to the medical profession must accept the status of purveyors. The physicians or laboratory investigator of the medical sciences shall not exploit for commercial gain the result of his studies. At the present time a commercial campaign is being carried on by a "laboratory" purporting to specialize in endocrine products. The mail of physicians is flooded with a series of postcards, each card recommending and suggesting the use of the proprietary product of this self-styled laboratory for conditions ranging from eczema to epilepsy, and from obesity to tuberculosis. This free postcard advice is reinforced by reference to "monographs" and a trade journal in which scientific medicine is systematically belittled as unpractical. This advertising campaign is ostensibly under the supervision of the enterprising Mr. Hyde, the merchant of the firm. Mr. Hyde is a profound admirer of the eminent Dr. Jekyll, the medical director. (Jour. A. M. A., Nov. 5, 1921, p. 1499.)

STATE SOCIETY

Ladies who accompany their husbands to the convention of the Medical Society of the State of California in Yosemite National Park next May 15-18, will find many things of interest to occupy their time while the delegates are busy with the scientific program.

Yosemite Valley, where the convention will be held, is the center of life in Yosemite National Park, and the sunny verandas of Sentinel Hotel and Yosemite Lodge are ideal for rest and quiet recreation. Every evening there is an entertainment of high merit at Yosemite Lodge, followed by a dance.

Those who love horseback riding can obtain good horses for use on the beautiful trails of the valley. The finest trail is that which winds between the great boulders and trees of the east end of the valley, emerging at Mirror Lake. In the west end of the valley, the trail generally follows the tortuous course of the Merced River.

Guides can be obtained for numerous scenic one-day trips by horseback outside the valley. Most famous of all these is the trip to Glacier Point by way of Vernal and Nevada Falls, a distance of eleven miles, return being made over the four-mile trail by way of Union Point. Another trip of intense interest takes riders up the opposite or north wall of the valley to Yosemite Point at the brink of Yosemite Falls. This affords magnificent views of the entire 2565 feet of Yosemite Falls. Eagle Peak, tallest of the cliffs known as "Three Brothers," can be visited on the same trip.

Few thrills can equal the ascent of Half Dome, which usually can be made about the time the convention will meet, dependent on how rapidly the snow has melted at the 9,000 foot elevation. A ride of nine miles leads to the foot of the "Elephant Back," the great hump to the left of Half Dome as viewed from Yosemite Valley. It is a short walk over this to the foot of the Dome, which looms up more formidably than the dome of the Capitol in Washington. A little way up, however, and all nervousness vanishes. Steel cables on either side afford reassuring grips. Those who want added security can wear leather belts with clasps which fit the cables, to be found in a box at the beginning of the ascent. As steps are provided on the steepest slope, and the "plates" of the granite are cracked at intervals, thereby affording secure resting places, most persons think the belts unessential and only imposing burdensome weight. Rubber sole shoes and gloves should be worn on the climb.

At the top of Half Dome is one of the grandest views in the world. The most notable feature of the picture, perhaps, is the intimate glimpse into Tenaya Canyon, the granite walls of which are so steep and smooth that less than a dozen men ever have achieved its passage.

Persons unaccustomed to horses need feel no fear at mounting one of the Yosemite animals, for they are trained and gentle. However, there are motor trips of great beauty for those who prefer to travel by automobile. The finest of these is the trip to the Mariposa Grove of Big Trees, oldest and largest of all living things, California's most distinctive possessions, for they can be seen nowhere else in the world outside this State. The trip from Yosemite Valley is one of great interest, as the road goes by way of Artist and Inspiration Points, makes a circuit of the entire Mariposa Grove, including the famous tunnel tree Wawona and the American Legion Tree dedicated to the Unknown Dead in the World War, and allows ample time to see everything.

Another fine motor trip is the tour of Yosemite Valley, following the road which traverses the valley on both sides of the Merced River, affording close views of the cliffs and waterfalls.

Those who drive to the valley in their own automobiles should not fail to take the splendid fifteen-mile ride between Yosemite and El Portal, terminus of the railroad. The road is like a boulevard, and follows the turbulent Merced River up its narrow canyon, through the "Gates of the Valley"—one of the most scenic rides in America. It is interesting to note that the paved, all year highway now being constructed between Mariposa and El Portal will follow this route into the park.

For those who like to hike there are walks innumerable, long or short, concerning which information will be given gladly at Yosemite Lodge, Sentinel Hotel or National Park Service headquarters. There is plenty to do in Yosemite—something to suit every taste!

One more thing—bring your camera. Few places can provide such wonderful opportunities for pictures.

GLACIER POINT, YOSEMITE VALLEY

COUNTY SOCIETIES

Alameda County Medical Association (as reported by Dr. Pauline S. Nusbaumer, secretary)—The Society met November 21, 1921, in the Oakland Health Center with sixty members present. Dr. J. Craig Neil in his paper, "Disturbances and Treament of Defects of the Vaginal Outlet," stated that the pelvic fascia is the true supporting structure of the pelvic viscera. Any disturbance of this fascia may result in various degrees of prolapse. Cystocele is really a hernia and usually causes the most troublesome symptoms. It may exist with or without a prolapse of the uterus, and should be dealt with independently.

During the child-bearing period, the fascia should be overlapped as in the treatment of hernia in other parts of the body, and the uterus suspended through an abdominal incision. After the child-bearing period, the best results are obtained by a vaginal pan-hysterectomy with a suspension of the vaginal vault by suturing the broad ligaments and the utero-sacral ligaments together, and an overlapping of the fascia of the anterior vaginal wall to support the bladder.

That the fascia about the rectum is not so well defined, but is available and should be utilized in the radical repair of rectocele.

Dr. J. F. McMath in his paper on "Dental Diagnosis," stated that the dentist is best qualified to render a diagnosis of dental diseases of the oral cavity. But that it is not within the scope of the dentist to advise for or against the removal of teeth when they are only suspected of being the foci of an infection, in such cases the dentist and physician should consult before advice is given.

He also stated that interpretation by radiologist should in no case be given to the patient, but should be considered as only an aid to the dentist.

The doctor believes that the physician should try to familiarize himself with the general problems of the dentist.

Dr. W. H. Strietmann in his paper, "Some Observations in Regard to the Achylia Associated With Pernicious Anemia," has never seen a case of pernicious anemia without achylia. Secondary anemias of any grade were usually accompanied by a diminished gastric function. The doctor reported one case, in which there was a typical picture of pernicious anemia, and which, after four years, has had no remission, and the blood count, on the day of the reading of this paper, was normal. A secondary case, in which the blood findings were those of a secondary anemia, during the course of eight months went into a pernicious type, ending fatally.

A number of other cases of varying degrees were reported, in all of which the treatment of the achylia was the only measure employed—all of which showed marked improvement.

These papers provoked full and interesting discussions.

Dr. William H. Irwin of the Oakland Emergency Hospital staff and Miss Lucile Pallady were married December 4.

The Baby Hospital of Oakland has just completed its campaign for help, and have received $20,000 for the support of its charitable work for babies.

M. J. Holt was convicted in the court of Superior Judge George Samuels for practicing chiropractics without a license. According to newspaper accounts, Holt has been engaged in his business in San Leandro and had taken over the work of J. E. Shah-Za-De, a "Persian chiropractor," who is now in the Alameda County jail. Holt was sentenced to fifty days in jail, declining to pay the $100 fine, which would have obtained his release. According to the newspapers, Holt was paroled by the Alameda County Parole Board, consisting of District Attorney Decoto, Sheriff Frank Barnett and Chief of Police J. T. Drew of Oakland.

According to the Oakland Tribune, Alfred Bach, proprietor of a newly opened rest-cure sanitorium, was arrested for violation of the State Medical Act, section 17, making it a high misdemeanor to practice medicine or advertise as a doctor without a license from the State. Permission for Bach to operate his sanitorium was granted by the Alameda County Council after a heated argument.

Sarah I. Shuey

On November 22, 1921, the Alameda County Medical Association was called upon to mourn the loss of one of its honored members in the death of Dr. Sarah I. Shuey.

Dr. Shuey was, perhaps, the most widely known woman both medically and philanthropically in the East Bay cities. She graduated with the first class in medicine in the University of California in 1876.

Dr. Shuey was the only woman to have held the presidency of the Alameda County Medical Association, and was also president of a former Board of Health of the city of Oakland.

When the campaigns for certified milk and a probation officer were launched in this city, Dr. Shuey was among their staunch supporters, giving substantial financial aid to the latter.

At the time of her death she was a member of the California State Medical Society, the A. M. A., the Merritt Hospital staff, and attending physician for girls in the Alameda County Detention Home.

In recognition of Dr. Sarah I. Shuey's splendid work in medicine, a movement is well under way to establish a scholarship for women in medicine at the University of California by public subscription, and will have the support of Dr. Shuey's many friends.

Placer County (as reported by Dr. R. A. Peers, secretary)—The annual meeting of the Placer County Medical Society was held in Auburn, Saturday evening, December 3, in the Masonic Temple. Dr. E. E. Ostrom, President of the society, presided.

The following officers were elected for the ensuing year:

President, Dr. C. J. Durand, Colfax; vice-president, Dr. H. N. Miner, Blue Canyon; secretary-treasurer, Dr. R. A. Peers, Colfax.

In addition, in conformity with the suggestion of the officers of the State society, Dr. E. E. Ostrom of Loomis, was elected as assistant secretary. Dr. E. E. Ostrom was elected as delegate to the 1922 State meeting at Yosemite. Dr. F. E. McCullough of Lincoln, was elected as alternate.

The literary program of the evening consisted of an address on Cardiac Irregularities, by Dr. Leroy H. Briggs, Assistant Clinical Professor of University of California Medical School, and a paper on Equilibrium in Vertigo, by Dr. Frederick C. Lewitt, Instructor in Surgery, at the University of California Medical School. The subjects presented were admirably handled, and evoked much interest and discussion.

Sacramento Society for Medical Improvement (as reported by Dr. Geo. Joyce Hall, secretary)—At the regular monthly meeting for November Dr. E. C. Turner discussed "Uterine Displacements and Causes." He gave a classification of displacements, including retroflection and prolapse; description of uterine ligaments; causes of displacements and demonstrated by use of the lantern, the seven displacements, depending upon the ligaments involved. He then took up flexions, lateral displacements and inversions. Dr. C. B. Jones discussed the paper.

"The Indications for Operation in Uterine Displacements" was the subject of Dr. G. N. Drysdale's paper. He divided the displacements into five classes and outlined the indications for operating these patients. Dr. Drysdale's paper was discussed by Drs. Rulison, Lindsay, Pitts and Hall.

Dr. J. W. James presented a paper upon the "Result of Operations in Uterine Displacements," which was discussed by Drs. Pitts, Thomas, C. A. Foster, Drysdale, Yates, Turner.

Dr. W. W. Cress, Sacramento, Dr. Smith, McMullin, Folsom, Dr. Christian, Galt, Dr. Stoltz, Sacramento, were elected members of the society.

The applications of Drs. Clattenburg and Azevedo were read for the usual course.

A committee of three was appointed by the Chair to take up the question of properly considering and wording a change in the present constitution so that the secretary be elected from the floor.

San Diego County Medical Society (reported by Dr. Robert Pollock)—The papers read before the San Diego County Medical Society at recent meetings comprise the following:

October 25—"Observations on One Thousand Cases of Fractures," with outline of modern treatment of the various types of fractures, by M. C. Harding, M. D.; "The Legislative Situation as it Concerns the Medical Profession and the Public Health of California," by Walter V. Brem, M. D., of Los Angeles.

November 8—"Fractures of the Skull," by E. H. Crabtree, M. D.; "The Clinical Value of Basal Metabolism," by R. J. Pickard, M. D.; "Secondary Radical Mastoid Operation," with report and presentation of cases, by C. W. Brown, M. D.; "Renal Diabetes," with report of case, by S. A. Durr, M. D.

November 22—"Indications for Cesarean Section," by T. F. Wier, M. D.; "Mastoiditis," by F. A. Burton, M. D.; "Myelogenous Leukemia," case report by M. M. Doria, M. D.

Sister Mary Michael, Mother Superior of St. Joseph's Hospital, recently celebrated her golden jubilee, representing fifty years of faithful service as a nun. The physicians of the staff recognized the occasion by presenting a substantial memorial to the hospital, and at a dinner tendered by the sisterhood to the staff, Dr. T. O. Burger, on behalf of the latter, delivered an address of appreciation of the faithful services and self-sacrificing devotion to the sick on the part of Mother Mary Michael and the members of the sisterhood to which she belongs.

The position of laboratory technician at the county hospital has been filled by the appointment of Mr. Maxwell, and Dr. Moser has been appointed to the position of house physician; he began his services November 1. He is a graduate of Rush Medical College.

The annual election of both the medical society and medical library association are conducted on the same day, December 13, polls being open all day.

San Francisco County Medical Society (as reported by Dr. LeRoy H. Briggs, secretary)—The society held four regular meetings and one special meeting during the month of November.

The special meeting was to hear an address by Dr. Wm. R. P. Emerson of Boston, on "Nutrition of School Children." The various programs show that an unusual group of papers was presented, but abstracts on only one of these papers has been presented to the editor.

Dr. S. L. Haas discussed the subject of "Fractures in Transplanted Bone," at the meeting of November 15. Dr. Haas stated that in studying the healing of fractures in transplanted bone, one must take into consideration two processes; namely, the healing of a fracture and the fate of bone after transplantation. Each one of these processes consist of an intricate system of regenerative changes, and when there is a demand for both to functionate at the same time, the question naturally arises as to whether there will be sufficient energy for the repair of a fracture in a transplanted bone, in addition to that required for the regeneration of the transplant itself.

In order to determine this question, an entire metacarpal or metatarsal bone was removed from a dog's foot, fractured in the center, and then reimplanted in the normal position or transplanted to the muscles of the back.

In seventeen observations there were only three complete failures of union, or lack of evidence of proliferation at the end of the fragments. Firm union occurred in five of the reimplanted bones and in five of the bones transplanted to muscle. The period of observation extended from 33 to 116 days.

Conclusions—1. Transplanted bone possesses sufficient inherent reparative powers to form a union of a fracture in a transplant, without the aid of any extraneous osseous elements. This is especially emphasized in the case of union of fractured bones imbedded in muscle.

2. A fracture will unite in a bone in which there has been a complete destruction of its blood supply. From this fact it would appear that disturbances in blood supply to one fragment of a fractured bone cannot be considered as a definite cause for non-union.

Sonoma County Medical Association (as reported by Dr. N. Juell, secretary)—The society met on December 8, with twelve members and one visitor present and twenty-five members absent.

Dr. Karl L. Schaupp read a paper on "Obstetrics," and led a discussion of the subject during the evening.

As this was the annual meeting of the society, the following officers were elected: President, Lafayette J. Wilson, Sebastopol; vice-president, Henry S. Rogers, Petaluma; secretary, N. Juell, Santa Rosa; treasurer, R. M. Bonar, Santa Rosa; censors, J. W. Cline, F. O. Pryor and J. Temple, Santa Rosa; delegate, W. C. Shipley, Cloverdale; alternate delegate, J. H. Shaw, Santa Rosa.

The Sonoma County newspapers are very properly agitating the need of a hospital for Santa Rosa. One paper states that, as a matter of fact, a hospital is as much a community affair as a church, a school or a courthouse. It ought always to belong to the community and be controlled by it. True, it is a workshop for the medical profession, but so is a school for teachers, a courthouse for lawyers and churches for preachers. It is strictly a public institution, a people's affair,

operated for the people's benefit, and should never be made a place for personal aggrandizement by any part of the medical or surgical profession.

Southern California Medical Association (as reported by Dr. Michael Creamer)—The sixty-fifth regular semi-annual meeting of the Southern California Medical Association was held in Los Angeles, Friday and Saturday, November 4th and 5th. Members were in attendance from all of the counties in the southern portion of the State.

Friday morning was devoted to clinics at the various hospitals, Saturday morning and the afternoon sessions being devoted to a scientific program given by our local men and members. Many excellent and unusual papers were given, followed by interesting discussion.

Dr. Alonzo Englebert Taylor, Director Food Research Institute, Stanford University, spoke on "The Practitioner's Conception of the Dietetics. Dr. Herbert McLean Evans, Professor of Anatomy, University of California, Berkeley, and Charles A. Kofoid, Professor of Zoology of the same University, gave the Saturday evening program. Dr. Evans' subject was "Interrelation between Menstruation and Ovulation." Dr. Kofoid spoke on "Protozoan Infections of the Human Digestive Tract." The evening sessions were much enjoyed by the members of the profession and such of the laity as were interested in these subjects. A vote of thanks was given by the society to these men for the excellence of their presentation.

The following officers were elected for the ensuing year:

Dr. William Duffield, Los Angeles, president; Dr. Robert Pollock, San Diego, first vice-president; Dr. Herbert A. Johnston, Anaheim, second vice-president; Dr. Egerton Crispin, Los Angeles, secretary-treasurer.

The spring meeting will be held in San Diego, April, 1922.

A joint meeting of the society with the Western Branch of the National Urological Society and Urological Section, was held on November 17, at Normal Hill Center. The following program was given:

Vesical Neck Obstructions and Their Relief. Wilbur Parker, M. D.

A Modification of the Differential Functional Test with Phenolsulphonepthalein. Anders Peterson, M. D.

Some Experiences in the Pathology and Treatment of Impotence and the Sexual Neuroses in the Male. H. A. Rosenkranz, M. D.

Intermittent Albumen, Its Etiology and Treatment. Lantern Slides. Alexander H. Peacock, M. D.

Merced County Medical Society (as reported by Dr. Brett Davis, secretary)—The December meeting was held on the 8th with Drs. Fountain, Davis, Fuller, Mudd, Parker and Kohl present. Much of the time of the evening was taken up in a discussion of the fee schedule. Dr. C. W. Kohl presented a paper on "Lobelia, Its Characteristics and Uses in Medicine."

This being the annual meeting there was an election of officers, and the present officers were re-elected to serve during 1922.

During the fall there have been twelve cases of diphtheria with seven known carriers, and six cases of scarlet fever.

Criminal Abortion

Recent inquiries of and correspondence with the office of the State Secretary appear to indicate the advisability of reviewing briefly the situation regarding criminal abortion. Penal Code, Section 275, reads as follows:

"Every woman who solicits of any person any medicine, drug, or substance whatever and takes the same, or who submits to any operation, or to the use of any means whatever, with intent thereby to procure a miscarriage, unless the same is necessary to preserve her life, is punishable by imprisonment in the state prison not less than one nor more than five years."

It is inspiring to read the Hippocratic oath which has been morally binding upon every physician of the world for more than 2000 years. The Principles of Medical Ethics, under which every ethical physician operates, also is quite specific and definite as to the proper attitude of the individual physician or organizations of physicians on this important question.

Honest boards of managers of hospitals, with the full support and co-operation of physicians' organizations, as well as hospital organizations, are safeguarding honesty and making these criminal procedures more and more difficult in an ever increasing number of hospitals.

Recently the State Board of Medical Examiners issued a statement on this subject that ought to be interesting and instructive to physicians. It is as follows:

"The commission of an abortion is a felony, and under the criminal statutes, all felonies are directly under the investigation and prosecution of local district attorneys.

The Medical Practice Act provides that the license of the individual may be revoked for the procuring or aiding or abetting or attempting or agreeing or offering to procure a criminal abortion. The legal technicalities involved in the determination of what constitutes 'proper evidence' under the criminal code makes it a most difficult problem for the Board of Medical Examiners to handle.

It is necessary to make the following showing:

1. A woman to testify that the alleged abortion was either attempted or committed on her.

2. It must be proven by substantiated evidence that said woman was pregnant at the time she visited the alleged abortionist.

3. It must be proven by corroboration of a third party that the alleged abortionist actually performed the abortion.

4. If a dying statement is taken of the individual alleged to be dying as a result of a criminal abortion, the code requires that a statement must be taken by a representative of the district attorney's office; the statement must open with the expression on the part of the testatrix that she is about to die or that she knows she is going to die, for without such a statement the courts will not admit in evidence a dying statement.

5. The penal code further provides that the individual who approaches another soliciting that an abortion be performed, is compounding a felony; i. e., is equally guilty with the individual who is alleged to have committed the abortion."

CORRESPONDENCE

We are in receipt of the following letter and article from Dr. Philip King Brown, President of the California Tuberculosis Association:

Editor of the State Journal of Medicine, Butler Building, San Francisco.

Dear Doctor:

The enclosed circular, if published in our Journal, will enable doctors to handle some of the worthy cases of tuberculosis among school teachers who might not otherwise be able to afford sanatorium care. I would appreciate it very much if the Journal would publish this notice.

Very truly yours,

PHILIP KING BROWN.

Fresno, Calif., November 10, 1921.

Dear Teacher:

Some years ago the late Mr. Bancroft E. Beeman of Los Angeles left a bequest to the California Tuberculosis Association, the fund to be used for whatever need seemed greatest to the Executive Committee. The fund has not been touched for the reason that we wished to use it where it would do the greatest good.

For some years past there has come to the Association's notice from time to time, teachers who were suffering with pulmonary tuberculosis. In some instances the inquiry has come for advice and information, but in many other instances it has been an appeal for help. Realizing the very poor remuneration paid to teachers, coupled with the fact that frequently they have obligations to meet that makes it impossible for them to stop work when their chances for recovery are good, many of them have been obliged to teach until they have become advanced cases. For this reason the Executive Committee has decided to use the Beeman bequest for a building for teachers at the Barlow Sanatorium in Los Angeles. Dr. Barlow is one of the foremost tuberculosis specialists in the United States, and it is for this reason that his institution was chosen. The above picture is a facsimile of the building. There will be private sleeping porches and dressing-rooms.

Until an endowment can be secured for the beds the building will be supported from the proceeds of the Christmas Seal sale. We hope that the teachers in the State who may need care will feel that this building is dedicated to them for their recovery from tuberculosis.

Very sincerely,

THE CALIFORNIA TUBERCULOSIS ASSOCIATION.

Taxing the Physician

"In ancient times a barbarous people presented a peculiar way of getting rid of their sins, by the priest laying hands on a goat, which was sent into the wilderness—the scapegoat. This didn't hurt the goat or do the people any good, except those who were Christian Scientist in embryo. Since that far-off time various peoples, institutions, societies and persons have been made scapegoats. At the present time there is one society specially under ban, though it has not taken to the woods.

The medical profession is the goat, but it cannot escape. There are men and women in this profession who violate laws and bring opprobrium upon all its members; there are statute laws against such offenses enacted for the public good, which should be enforced by the public legal machinery, but in this regard the medical profession is an exception to all rules; its members must bear a special tax of two dollars per capita for the purpose of enforcing State laws, which in all other cases are enforced at public expense. Members of the profession are taxed on their possessions as high as anybody. Why should they have to pay for the prosecution of violators of the law any more than other professions? Are lawyers taxed a special sum to prosecute offenders in their ranks?

There are wicked, vicious and careless men who are willing to make money for themselves by encouraging the use of narcotic drugs and furnishing such things to the unfortunate victims of an acquired appetite—such are criminals—but very few of them are recognized members of the medical profession. The Harrison law, in many respects, is one of the wisest, but why should it penalize every honest doctor and tax him three dollars a year for the privilege of relieving the suffering of his fellow creatures?

The Prohibitory law is a public blessing, but why should it impose such burdens upon physicians who use alcohol only in a proper way? Why should it give such opportunities for selfish immoral men to make money out of the victims of the drink habit? Can anything be more supremely absurd than to give a doctor the privilege of writing one hundred prescriptions in a month and making it criminal if he writes one more? Who can tell how many of his patients will need some form of alcoholic medicine next month? Think of the tyranny of a law which will not allow a druggist to use a little alcohol in a prescription required to effect solution, because the writer, though a regular physician, has not applied for that contemptible permit to write one hundred prescriptions for a pint of booze. Who wants such a permit except the man who is willing to use it in pandering to the degradation of his fellows? Honorable physicians have to avail themselves of this permit, but I dare say every one despises such a law.

Why is the profession so tame and submissive? The unfair and ridiculous laws to which we are subjected would provoke a revolution if applied to any other class or profession."

F. E. COREY, M. D.

BOOK REVIEW

The Evolution of Disease. By Prof. J. Danysz, Chef de Service, Institut Pasteur, Paris. Translated by Francis M. Rackemann, M. D., Philadelphia and New York: Lea & Febiger. 1921.

On the basis of the reactions of the arsenobenzenes with blood serum, an elaborate theory of the "evolution" of disease is built. A critical consideration of the book will be aided by the knowledge that the basic experiments have been repeated by other observers with results, which, to put it mildly, modify any interpretation of the original facts in the case.

Nevertheless, as the author feels that there is a "complete identity of the reactions between serum and arsenobenzene on the one hand, and between serum and the biologic antigens on the other," he proceeds to develop analogies in every field of immunity.

The reader will appreciate his ingenuity, but is apt to feel that "in order to explain these things there has been created a complicated and barbarous terminology which has, incidentally, the great inconvenience of giving grand illusions with a precision which does not exist." J. O.

California Association of Medical Social Workers

(Reported by Miss Edna J. Shirpsey, secretary)

The Association held a meeting in the rooms of the San Francisco County Medical Society October 21, and another meeting on November 18. The former meeting was addressed by Mrs. John Collier on "Health Habits of Children," and the latter meeting by Dr. William R. P. Emerson on "Nutrition." Miss Margarite Wales, chief social worker of the Stanford University Medical School and Hospital, discussed the aims and purposes of the organization of medical social workers.

The speaker emphasized the importance of developing the medical aspects of social work. The great advantage of co-ordinating the work of medical social workers and the early organization of these workers with the medical profession was emphasized. Medical progress in the prevention and cure of disease must go forward as team work under the leadership of the medical profession, if it is to fulfill its function of securing the greatest good to the greatest number from the services of physicians and to protect the members of the medical profession against wasted effort and misuse of their services.

"It is especially important for medical social workers to get together, not only to work out the problems that belong so definitely to their particular province, but some opportunity must be offered for them to hear the opinions of their co-workers in the medical profession."

"For some years social work in general has had a distinct place in the college curriculum." Medical social work is much more recent, and such a course is, at present, offered in only one medical school in this country.

At the business meeting of the association, Dr. Ray Lyman Wilbur of Stanford University Hospital and Dr. W. E. Musgrave were voted honorary members of the California Association of Medical Social Workers.

Dr. Edna L. Barney, Edna F. McInerney, Marion Maxwell, Ottilie Haas, Dr. Jessica Peixotto, Rose Steinhart, Lucy Ward Stebbins, Olive McGinnis, Regina P. Horton, Sophie Mersing, Katherine Wynne, Margaret Surmoundt were elected to membership.

DEATHS

Woolley, Frederick Marion. Died in St. Helena, Calif., November 15, 1921. Was a graduate of the College of Osteopathic Phy. and Surg., Los Angeles, Calif., 1917. Licensed in California 1920.

Smith, George Sidney. Died in Half Moon Bay, Calif., November 21, 1921. Was a graduate of University of California 1879. Licensed in California 1880.

ORIGINAL ARTICLES

THE OPERATIVE TREATMENT OF STRABISMUS *

By WALTER S. FRANKLIN, M. D., F. A. C. S., and WARREN D. HORNER, B. S., M. D., San Francisco.

In this paper we present a resumé of forty-eight consecutive cases of muscle deviation which were treated surgically. The tables give exact details of results and other data. It is our firm conviction that no one method or procedure is superior universally, and that the end-result is more a matter of the finer details and proper following out of accepted published operations. For example, our results have been unsatisfactory with the Briggs clamp. A colleague uses this method exclusively and claims to find it satisfactory. By analogy we feel that we must have missed one or more of the finer but essential details in the published reports of the operation and its application. This point explains the multitudinous procedures and operative methods for the same condition. The author of a method obtains certain results. It is published and followed correctly, that is, presumably, but the results differ and other methods are conjured to obtain more satisfactory cures.

The Reese resection has proven thoroughly reliable in our hands, but it is essential to follow the details of the operation minutely. Occasionally a new interne or a change in surgical nurses has resulted in some modification in technic, for example, forgetting to properly wax the sutures—the annoyance and possible failure cannot be exaggerated.

We wish to emphasize the cultivation of one operative method and its application to all cases in which it applies. In this manner our judgment of quantity, so essential in muscle deviation cases, is sharpened and the operation will be done under like conditions. The majority of our cases were operated upon under general anæsthesia. It is difficult to estimate the amount of shortening required, due to the changed conditions and relaxation from the anæsthetic, but one acquires a sense of proportion after a few cases. In our experience the nervous shock to the patient under a local anæsthetic is greater than the possible nausea following a general anæsthetic. The surgeon has more freedom and is under less tension while operating upon the patient under narcosis.

The Reese resection was performed twenty-two times. The results were universally good with the exception of a few cases in which further operative measures were necessary. We have found that the suture, its strength and proper waxing, are the pivotal points of this operation.

An advancement was not done in any case. The scleral puncture has never appealed to us. The uncertainty of depth and having noted two cases of perforation in the practice of colleagues, have determined us against this procedure. We do not doubt that others may obtain satisfactory corrections by some form of advancement, but it is not our choice.

The clamp was utilized in nine cases. According to its author, a snip is made below the muscle, which we supplemented with a counter-puncture above. By this modification, the entire muscle, capsule and conjunctiva were included in the tucking. The cases were done under local anesthesia. We are free to admit that the results were uniformly bad with the exception of one case of esophoria, which is the only phoria one included in this series. The clamp changes its position after a few days, the upper end slipping downward, and in all cases careful attention was given to proper tightening, so much so that the forceps were always removed with difficulty. All cases were greatly undercorrected. Following the first poor results, special attention was given to the muscle-loop pulled through, and its fastening.

The Todd tucking was employed eleven times, and here we noted far better results in the later cases. The difficulty in placing the suture with the muscle under tension from the tucker, is greatly simplified by using a small curved mounted aneurysm needle. This latter modification can be recommended.

A few cases presented rather unusual features. In one the Reese resection was done, following a long period of radium therapy, for double-sided tubercular keratitis. The eyes had been quiescent and considered cured for over a month before the operation. The reaction on the operated eye was violent. It consisted in puffiness of the lids and marked chemosis, exophthalmus and symptoms of strangulation. We feared an orbital phlegmon, but the cellulitis cleared, with no bad sequellæ.

A young boy with congenital paralysis of the left external rectus received a moderate result by a transplantation of the outer half of both vertical recti muscles.

A young girl was scheduled for a resection. After performing the tenotomy, the eye became so free and limp in its motions that nothing further other than a restraining suture was attempted.

* From the Department of Ophthalmology, University of California.

This case presented but little improvement for her convergent strabismus, and required reoperation.

An adult, a marine, was operated upon for a convergent strabismus. At various times he had free and typically projectile vomiting sufficient to bathe the cut surfaces of both eyes and the surgeons with stomach contents. Copious lavage was resorted to, and fortunately no infection followed.

A young boy acquired a partial retinal detachment, following a small perforation of the sclera while snipping a buttonhole in the tendon for a partial tenotomy.

No attempt has been made to describe the operative technic employed, as we lay no claim to originality. The cases were operated upon according to the accepted methods, and we changed to the different operations to prove our first-stated contention, that it is the operator and not the particular method chosen which gives results. We cannot too strongly emphasize the cultivation of one operative procedure varying same only when forced to by its nonadaptability.

This is especially true for those of us who have not an abundant material at our disposal and who operate rather infrequently.

One cannot be too cautious in predicting the end-result from one operation, and the patient should be warned as to the possibility of a repetition.

We no longer assume any arbitrary age limit in determining when to operate. Every case must be decided individually. It may be stated here that orthopedic methods were consistently resorted to where indicated, and in general the surgical intervention was considered as the final means of obtaining a straight eye.

Age of Patients in Ten-Year Periods

First ten years	12
Ten to twenty years	10
Twenty to thirty years	21
Thirty to forty years	4
Over forty years	1

UROLOGICAL DIAGNOSIS*

By GEORGE F. FARMAN, M. D., Santa Barbara, Calif.
From the Santa Barbara Clinic

The diagnosis of diseases of the kidney is becoming more and more a matter of scientific accuracy. In a large measure this is due to the perfection of cystoscopic technique, radiology, pyelography, blood and urine analysis, and renal functional estimation. Opinions as to the proper treatment are frequently at variance, but the fact remains that our estimate of kidney pathology may be made quite accurately in by far the great majority of cases.

In spite of these facts, there still exists a widespread laxity among members of the medical profession in regard to the diagnosis of genito-urinary conditions. This is mainly due to three factors:

1. The common practice of empirical treatment in the genito-urinary tract.
2. A lack of knowledge of the pathology of diseases of the kidney.
3. The necessity for special examination in the diagnosis of kidney conditions.

The common practice of empirical treatment in lesions of the genito-urinary tract should be discontinued. Too often we prescribe for symptoms of urinary disease, without sufficient study to determine the true cause of the condition. Fortunately many symptoms disappear temporarily under empirical treatment, but the pathological process may remain to further damage the kidney, and allied organs.

Roughly, we separate cases of urinary disease into two great groups, Nephritis, and Cystitis. In treating nephritis we outline a diet and in treating cystitis we often prescribe a drug, while the important causes of both diseases remain unrecognized and untreated. Cases of supposed simple nephritis we may later discover are cases of renal tuberculosis, renal calculi or infected hydronephrosis, and likewise supposed simple cases of cystitis we later discover are cases of bladder stone, bladder tumor, prostatitis, or disease of the upper urinary tract.

A correct understanding of the pathology, as well as the chronic nature of diseases of the kidney is necessary before correct diagnosis can be made and adequate treatment administered. Years may elapse between the onset of kidney lesions and their culmination into frank disease entities. Careful questioning of the patients usually illicits a history of previous urinary distress or discomfort along urinary tract.

Acute urinary diseases of the inflammatory or obstructive type usually are manifestations of underlying more serious conditions. Typical of this are the cases of acute pyelitis manifested by the symptom complex—pain in the back, frequency, burning, and pyuria. Acute pyelitis occurs more often in those type of kidneys favoring infection of the real pelvis due to abnormal mobility, congenital or acquired anatomical defect. Acute kidney colic is caused by obstruction to the urine outflow in some part of the urinary tract. The obstructing process may be within the lumen of the urinary tract, common examples of which are pelvic and ureteral calculi; within the wall of the tract iself such as inflammatory or traumatic stricture or without the lumen, the most common example being the pregnant uterus. Repeated acute attacks of inflammation or obstruction lead to dilatation and distortion of the urinary tract, favor infection, urinary stasis, stone formation and destruction of kidney tissue. Kidney cells once destroyed are not replaced, but their function compensated for by hypertrophy and hyperactivity of the remaining normal tissue.

The kidney is not a readily accessible organ, which no doubt accounts for delay and failure in diagnosis of kidney lesions. We are want to make a pass at kidney palpation, do a hasty urinalysis, and send the patient on his way with a prescription for one of the many urinary drugs. If we are to recognize kidney lesions at their incident, we must put our patients through a routine of careful history taking and physical examination; through routine radiography of the entire urinary tract, through detailed blood and urinary analysis, and through the usual urological procedures.

Cystoscopy offers a safe, rapid, objective means of examination invaluable in the accurate localization of lesion of the genito-urinary tract; and every case presenting symptoms should have the benefit of such examination unless contra indicated.

* Read before the Santa Barbara County Medical Society, May 23, 1921.

The urologist stands in mid-position between the internist and the surgeon and insures the better surgical treatment of medical patients and the better treatment of surgical patients.

The physician is inclined to delay and the surgeon to pass up urological study. There is need for the closer correlation of the medical and surgical viewpoint in urinary diseases.

Illustrative of the above statements we cite the following case:

CASE REPORT

Mrs. B. O. Complains of recurrent attacks of right-sided colic and constant backache. Fourteen years ago during her first pregnancy she had considerable backache on the right side. Three years later she had a definite and rather typical attack of renal colic. There have been a number of similar attacks since that date, the last one eight days ago.

The patient is 34 years of age, the mother of two children, and aside from the renal colic has enjoyed good health. The right kidney is palpable as a tender mass opposite the umbilicus. No other physical findings of importance.

Cystoscopy shows mild generalized cystitis, marked congestion and cystic edema below right ureteral orifice. The right ureteral orifice appears larger and more retracted than normal.

The bladder urine contained 160 pus cells per c. mm.; the urine from the right kidney was very dark in color, ammoniacal, contained 22 pus cells per c. mm.; urine from left kidney clear, and contained 20 pus cells per c. mm. All three specimens were culturally negative and negative for tubercle bacilli.

The phthalein test showed an output of 10 per cent on the right side and 40 per cent on the left.

Plain X-rays made with shadowgraph ureteral catheters insitu, showed a calcified circular shadow, the size of a hazelnut at the end of the right ureteral catheter.

Pyelogyram of the right renal pelvis, using 24 cc. of a 10 per cent solution of thorium nitrate for the opaque medium, shows the right kidney in a low position about midway between the twelfth rib and the iliac crest. There is large hydronephrosis of the renal pelvis; destruction of the minor calices with clubbing of the ends, and the formation of individual rounded areas.

From the above data a diagnosis of nephrolithiasis and hydronephrosis was made. Plates made two days later continued to show the presence of the calcified shadow in the right kidney area.

Right nephrectomy was performed February 25. The patient left the hospital twelve days after the operation following an uneventful convalescence.

Pathology: The kidney measures 11:25 cm.x 5.3x5.0 cm. and weighs 187 gm. There is a navy bean-sized, brown, mulberry-like, hard calculus lodged in a minor calyx of the lower pelvis. The renal pelvis is divided into three compartments, the pelvis proper, the upper major calyx, and the lower major calyx. The mucosa of the pelvis proper is thickened, edematous, and stained brown by old blood. The wall of the pelvis is tough, thickened and sclerotic. The upper major calyx forms one large single sac, connected to the pelvis proper by a narrow diverticulum-like opening. The mucosa of the upper calyx appears quite normal.

The lower major calyx is further subdivided into three or four minor calices, in one of which is lodged the calculus.

A large amount of fat and tough fascial striae enclose the kidney hilum and pedicle, showing evidence of peri-renal inflammation. Histological sections show chronic glomeurlo nephritis; parenchymatous degeneration of tubules; slight intertitial changes.

Chronicity of Kidney Disease.—The outstanding features in this case are first, the chronicity; second, the pathogenesis; and third, the method of cure.

This patient gave evidence of urinary disease for fourteen years. The principal symptom was a more or less constant backache and occasional attacks of renal colic. Too ofen these patients are classed as neurotics. An organic basis usually may be found for the neuroses accompanying such genito-urinary symptoms. In this patient the constant backache was due to the abnormal mobility of a chronically inflamed kidney.

The method of cure in this case may seem a bit radical. We are taught that simple pyelotomy, for stone in the renal pelvis, is the operation of choice. This is true of uncomplicated cases of pelvic stone, but where abnormal mobility or hydronephrosis exists total nephrectomy offers the greater percentage of permanent cure.

Compulsory Health Insurance, State Medicine, Venereal and other free clinics, and many other social uplift schemes requiring the energy and thought of the members of the medical profession are but stepping stones to socialistic medicine, which not only puts individual incentive and practice out of commission but will place the whole public under the rule of inefficiency. Perhaps we hear someone say, "Well, what is to be done?" to which we answer, in the words of the Illinois Medical Journal, "quit giving approval to these various cross-eyed medical uplift schemes advocated by erstwhile reformers and public welfare peddlers who usually see in their schemes some avenue for profit." Some of our medical men who have acquired wealth and social position seem to think that it is quite the proper thing to approve of these various uplift schemes in order to bask in the sunshine of the mighty, forgetting that in the security of their own economical position they are tramping upon the toes of their less fortunate brethren. In reality this "dear public" and "love of humanity" stuff is greatly overworked. (Editorial Notes: The Journal of the Indiana State Medical Association, page 435.)

Medical Peonage in Michigan—Those interested in the developments of socialized medicine should read the press clippings and editorials in the lay and medical journals of Michigan and nearby States. The whole thing makes a sorry story of the harm a few unchained parlor socialists can do when they get control of the policies and practices of a great university. It is to the credit of the good name of Michigan physicians that, in order to carry on its present policies, the State University must import recruits.

TONSILLECTOMY

By LIEUTENANT JOHN W. GREEN,
Medical Corps, U. S. Navy, 814 Carolina Street, Vallejo, California.

The only excuse for further discussion of tonsillectomy, is the continued failure of a great many operators in carrying out a perfected technique which results in complete removal of the tonsil and its capsule, at the same time avoiding postoperative adhesions and contractions, and having a good cosmetic result in the throat. It is much satisfaction to the patient, a year or two after operation, to have it said, "That was a splendid operation," instead of, "In my opinion there are fragments of the tonsil remaining which must be removed." A good, thorough operation should be done much oftener than is accomplished at the present time. After some ten years of effort and constant thought, and for the benefit of those who have not a perfected technique as yet, I will endeavor to set down a few points which may be of material assistance in deciding when and how to operate successfully.

The indications for operation are, chronic tonsillitis, frequent recurring attacks, with or without joint pains, tachycardia, anemia and choreform movements; hypertrophy with difficulty in swallowing, breathing and speaking, chronic eustachian salpingitis, catarrhal otitis media and chronic throat cough.

It is considered necessary to estimate the speed of coagulation of the blood prior to operation, to rule out the various types of bleeder. I firmly believe that anything above six minutes may result in serious hemorrhage, and the patient should be so advised and treated with horse serum, calcium lactate and gelatin for a period of ten days before he comes to operation. It is also considered inadvisable to operate women at or near the time of menstruation. Do not operate during an attack of tonsillitis. The patient may have diphtheria or scarlet fever.

The choice of anesthesia for children is ether, given with a pump and suction machine. This simplifies the technique and saves time. A local anesthetic is preferable in adults. More careful work can be done by this method of anesthesia. You can see at all times just what you are doing. I prefer 1 per cent procaine or novocaine with the addition of three minims of 1-1000 solution of adrenalin chloride to the cc. of anesthetic. In extremely nervous adults a hypodermic injection of morphine and atropine, perhaps supplemented with painting the pharynx and faucial pillars with 10 per cent cocaine solution, and with a little reassurance by the operator, will dispel all their apprehension.

The patient should be prepared for the operation by having received a cathartic the night before and by not having taken food or fluids for six or seven hours. Wash the face with tincture of green soap and follow with 1-3000 bichloride solution. Cover the scalp and body with sterile towel and sheet. The pus basin used for collection of sputum should also be sterilized. The instruments should be properly boiled and the surgeon's hands should be scrubbed and gloves should be worn.

When using a local anesthetic, inject about ¾ cc. in each of three points on each side. Inject behind the anterior pillar, in the supratonsillar fossa, posterior to the anterior pillar at the lower pole of the tonsil and midway between these two points. The depth of the injection should not be over an inch and should not extend through the capsule into the gland. The joints of the syringe, as well as the piston, should be tight to insure proper infiltration of the tissues. By injecting the left side first and later the right side, one can operate immediately upon the left tonsil without pain. In this way no time is lost. It is not necessary to wait fifteen or twenty minutes for complete anesthesia.

The method of choice is dissection and enucleation. Some operators prefer a Sluder, Beck-Sluder or La Force tonsillectome; but I prefer dissection and snare, inasmuch as, with a large amount of scar tissue from former operations or abscesses, all operators are obliged to resort to the dissection method. Care should be taken not to injure the palato-glossus or the palato-pharyngeus muscles.

Start the incision at the junction of the capsule and mucous membrane along the anterior pillar and carry it down to the fossa triangularis, being careful to make it superficial. If the incision is deep, the capsule is opened and dissection becomes very difficult. Use a knife or scissors for the continuation of the dissection. Blunt instruments and force will produce pain. I prefer to use a Betcher tonsil scissors for this work. The instrument has a long handle and a blunt blade curved on the flat. Work close to the capsule, cutting or spreading with the blades in that direction. The scissors will follow the capsule very closely, leaving practically no muscle fibers on the capsule. Where scar tissue is present a much more extensive dissection is necessary than in the uncomplicated case, because the snare may strike the scar and ride over it, deeply in the muscles or pass through the capsule, leaving a part of both tonsil and capsule in the wound. Carry the dissection well down the posterior pillar on its anterior surface and be careful, in putting on the snare, not to include the uvula. Its removal is not serious from an anatomical standpoint, but from the cosmetic angle it is a most serious blunder.

In applying the snare, point the barrel toward the junction of the anterior pillar and the base of the tongue. Both tonsils can be enucleated by this method in from ten to twenty minutes, depending on the conditions. This includes the time spent in infiltrating the tissues. All bleeding points should be caught and ligated with No. 0 plain catgut on a small full-curved needle. Catch the bleeder with a tapering-pointed hemostat. Pass the needle through the muscle just below the point of the hemostat, pass the long ends of the ligature over the hemostat and tie a square knot. Such a ligature will not become untied or slip off.

The use of styptics is not desirable on account of sloughing and secondary hemorrhage. The most common bleeding encountered is in the supratonsillar fossa and is usually venous from the plexus of veins surrounding the gland. Branches of the posterior tonsillar artery, superior tonsillar artery and the anterior tonsillar artery are some-

times cut. There is very little danger of injury to the carotid. Rents in the pillars should be repaired immediately. Be sure to have the incision line (line of the anterior pillar) straight and clean and uniform on the two sides. The height of the incision should be alike on the two sides to have the best cosmetic result.

If you would avoid serious hemorrhage at all times, keep close to the capsule with your dissection. This will also avoid mutilation of the pillars with serious fatiguing adhesions and contractions of the pillars. Undue speed in operating results in hemorrhage and unsatisfactory results. Take your time. The primary incision is the most important and avoid passing through the capsule at this time. When the operation is finished, inspect both the tonsillar fossæ and the tonsils to see that no capsule or gland remains. This will insure favorable criticism when the throat is inspected by the next man who may be called upon to examine the case. It is most embarrassing to have it said that your work must have been that of an amateur.

Following the operation, the patient should be put to bed, without food or drink for at least twelve hours. He should be advised to keep as quiet as he can and not to attempt to clear the throat. An ice collar should be placed about the neck. The following day liquid may be given, and the following day, soft diet. The patient should gargle his throat frequently after the first day until complete healing takes place. As a rule the wounds will heal completely in from ten to fourteen days, in the absence of complications or constitutional disease. In case of mutilation of the pillars, healing will be very slow. In some cases the cervical glands will become infected, but rarely suppurate, and they do not, as a rule, require removal. In such cases, tonics, good food and fresh air will usually effect a cure. About the third day inspection often shows what appears to be a very bad looking wound, due to swelling in the plica triangularis, which is many times covered by follicles of lymphoid tissue. At the time of operation it is well to inspect this area and remove the lymphoid tissue, if necessary. Lung abscess occasionally occurs with local as well as general anesthesia. I know of no way to prevent this accident other than the most scrupulously clean operating. As a rule the voice is improved in strength and quality, and rarely suffers fatigue as the result of a well planned and carefully carried out technique.

In closing, a word should be said with regard to dealing with hemorrhage. Primary hemorrhage will rarely occur if the bleeding vessels are ligated with an anchored suture as described. Provided it cannot be controlled by the above method, a sponge may be sewn between the pillars, but should not be allowed to remain for more than thirty-six hours, for fear of sloughing and infection. Various sorts of tonsil clamps have been devised for control of severe hemorrhage, but they are painful when applied, and also produce sloughing when allowed to remain long in place. The usual treatment for severe hemorrhage has to be resorted to in rare cases—e. g., bandaging of the extremities, raising the foot of the bed, hypodermoclysis, Murphy drip and blood transfusion after typing. Morphine in full doses will relieve the extreme anxiety of the patient. Intravenous injection of iron cacodylate will serve well as a blood builder and tonic following hemorrhage, and assures the patient that you are doing something to speed up his convalescence and recovery.

INADEQUATE PERSONALITY WITH SPECIAL REFERENCE TO ITS INFLUENCE ON BOTH DIAGNOSIS AND TREATMENT

By ROSS MOORE, M. D., Los Angeles.

Someone said or wrote, "There is nothing so real as the imagination." He meant the same thing the other sage did, who said, "Nothing ever exists except first in the imagination."

This paper does not deal with things of the imagination but does seek to make real a phase of diagnosis and therapeutics that is considered by many busy practitioners so unreal as to be almost imaginary. We are at a sort of turning point in the practice of the healing art. The profession is gradually realizing that the man whose eye is glued to the eyepiece of the microscope is not in the position of most usefulness to a suffering humanity.

It is a worthwhile task for the Neuropsychiatrist to help the profession in its efforts to practice good healing. This can best be done by insistence on that idea so well expressed in the last line of an old poem:

" 'Tis not the body but the man is ill."

This means the study of personality in its relationship to disease.

My thesis is this: Symptoms and symptom complexes may be due not only to organic and functional causes, but also to what might be called temperamental causes. Surgeons naturally tend to believe in the organic basis of most symptoms. Frequently before and occasionally after operation they admit that seemingly organic symptoms may have had a functional basis. Physicians more readily agree that functional causes may be responsible for symptoms and symptom complexes that look decidedly organic. The daily experience of Neuropsychiatrists leads them to add "Temperament" to these other two sources of symptoms, thus completing an etiological trio in my opinion capable of including all disease manifestations. In psychiatry this etiological temperament is spoken of as "psychopathic personality." A more inclusive term to designate what I have in mind is, "inadequate personality." The word "inadequate" almost exactly expresses my concept of this personality. It is an etiological rather than pathological personality. It includes all types of personality likely to give rise to symptoms, but should not be applied to the feeble-minded.

If I succeed in elucidating my thesis by proving that temperament should be equally considered as a cause of disease alongside of the functional and organic causes, then a corollary appears; viz. that,

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

whatever symptomatology is actually due to the inadequate temperament must be considered as being permanent.

Temperament is just as inborn and fixed as the color of one's eyes or the length of one's nose. Symptoms due to temperament should not be called symptoms, but characteristics.

This paper is written to call attention to some of the types of inadequate personality, so that the therapy of general practice may be directed away from an effort to cure characteristics. These characteristics are to be brought to the attention of the patient in their true form so that he may adjust himself to considering them as permanent handicaps, and therefore not be irritated by their presence but rather learn to ignore them in his program through life.

Speaking generally, the personality of an individual may be inadequate in four ways: (1) physical, (2) neural, (3) moral, (4) emotional. A given individual may exhibit one or a combination of these types.

The psysical type of the inadequate exhibits in his physical makeup an unbalance so extensive as to make him unfit to cope with physical emergencies. He may be small and slight of build or tall and very slender. He frequently has abnormally small hands and feet, as if nature realized the sorry joke she was perpetrating when she allowed the individual to be born, and tried thus to mark him a parasite and not a worker. This physical type has been quite well recognized for a long time. He is, therefore, less misunderstood by his hurrying fellow humans, and his busy physicians. Physical inadequacy is found associated with neural and emotional inadequacy very frequently. Probably less frequent with moral.

The neural inadequate turned up frequently in the work of the neuropsychiatrist in the army both in this country and France. I personally came to the conclusion that he was the one particular type of the inadequate whom I felt must be kept from front line service. He is usually bright, smart and active both mentally and physically, but with little reserve. He is parallel in his neural makeup to the person whose mind or intellect is characterized by the term "shallow." Superficial observation would not lead to the detection of his actual inadequacy, because he learns to camouflage it by a show of transient vigor, much as the shallow intellect can cover itself by a temporary show of brilliancy.

The moral inadequate is the individual who stopped his human or civilized development at the period in life when it is said that a child is inherently cruel. He has modified his outlook on life only as much as is necessary to keep him from getting into uncomfortable situations. He cannot sense what is meant by altruism. He is a curious combination of thoughtless impulsiveness with carelessness of consequences.

The emotional inadequate is very difficult to describe. He is not necessarily emotionally unstable and may even appear emotionally barren. His type merges quite insensibly into that of the repressed individual—the unfortunate who has had emotional sterility thrust upon him. Indeed it is quite to be expected that the emotional inadequate will come of repressed parentage and, therefore, will be both temperamentally and developmentally inadequate. The experiences of life will have more influence on this person than on any of the other types of inadequacy. Whereas the neural inadequate will usually react very quickly to his surroundings, the emotional type may do the same or apparently not react at all. Nevertheless, his emotional reaction to his experiences and his suroundings is going on deep within him and inexorably produces a pathological personality later on because of that immobility which is inborn.

I have suggested these four types for purposes of description. They seldom exist in pure form. Whether they are pure or all mixed together in a given case is quite immaterial, providing it is recognized that they actually do exist. Inherent or inborn inadequacy being established, it remains for the therapist to manage his patient, his patient's friends, and the general surroundings and conditions so that these characteristics of inadequacy are adjusted for rather than an attempt made to remove them. The above presentation is totally incomplete and is designed simply to be suggestive.

CASE REPORT

A case in point. Unmarried girl, twenty-two. Physically small. Small unused hands. Father, a quiet, reserved successful business man, who knows how to work, but not how to play. Mother physically inadequate and repressed. Patient developed cardiac lesion at twelve years of age. Has been an invalid ever since. Dabbled a little in art, and has read widely in field of romance. Has very good taste, uses good English, and is very pretty and attractive. Considers herself a hopeless invalid and, therefore, has no outlook on the future. Romances about life and marriage, but does not look upon any young man as attainable in the way of a husband for herself.

Here is a combination of physical, emotional and neural inadequacy, with the added handicap of maternal repression and insistence on the fact of invalidism.

It was determined that the cardiac condition was negligible. It remained to determine how much of the residual symptomatology was temperamental and permanent, and how much was due to maternal inadequacy and the inevitable introspection of the shut-in. Some months of therapeutic effort sufficed to clear up most of the symptomatology due to these latter causes. The result was that the patient began to fearlessly ask questions about life and sex, and self; began to think and act for herself; began to make a place for herself in society; began to attract the young men—in short, is approaching a condition that should be considered normal for her. She had gone along for several years having medicine given her for her heart, being curetted, being sanitariumed, and being invalided, because an effort was being made to correct the whole clinical picture.

If this concept of inadequacy had been in the minds of her physicians, they would have made this differentiation between removable and irremovable symptoms; would have cleared up the former,

and helped the patient to adjust her life so that the latter would be the least possible handicap.

CONCLUSIONS

1. There is such a thing as inadequate personality.

2. It is congenital and irrecoverable.

3. It manifests itself in the physical, neural, moral, and emotional parts of human nature.

4. It gives rise to symptoms which may simulate closely those of organic or functional disease and which may be mistaken for evidence of the latter.

5. It is usually associated with acquired illness.

6. When it is so associated all therapeutic effort aimed at relieving symptoms caused by it will end in disaster.

7. When its presence is recognized and taken into therapeutic consideration much improvement can be brought about in the patient.

8. Its presence will be determined by careful consideration of the history of the patient rather than by examination.

9. The history necessary for diagnosis does not relate to previous illnesses sustained, but to the reaction of the patient to his environment and all data capable of giving a true estimate of that intangible thing called personality.

THE SPECIALIST AND HIS OBLIGATION TO THE PROFESSION *

* Chairman's address before Urological Section.

By GEORGE G. REINLE, M. D., Oakland

As members of the medical profession we hold an unusual position in the social structure and we have an obligation to render our best service to the public. We stand in the generally accepted position of mentors and advisors in matters pertaining to health. Less generally recognized, however, and of much the same character, is the obligation of the specialist to the balance of the medical profession. As the public has conferred upon the whole profession certain privileges and exemptions which must be repaid by a special regard, so has the profession permitted the specialist certain exemptions and is, in return, entitled to even greater considerations.

I should like at this time to call your attention to some of those things about which you have all thought, and upon which you all entertain well-developed ideas, which, unfortunately, you either keep to yourselves or express only in private. I have reference to those obligations which the specialist owes to the profession, and, conversely, what the specialist should expect from the profession in general.

Specialists are prone to be critical in their views, and intemperate in the expression of their opinions, concerning the character of the work accomplished by men doing both general medicine and general surgery. Not infrequently we hear complaint that cases which drift to the specialist have been treated overlong and inappropriately by those unprepared to render the proper service. This fault applies to specialists in every line. The oculist inveighs against the neglected case of tracoma which has lapsed into hopelessness, and he also has other things to which he takes exception, more or less privately, or to lay friends. The aurist bewails the palliative treatment of running ears, which come to him as acute mastoiditis. The urologist finds fault with infected kidneys, tubercular and otherwise, which have been treated by useless bladder irrigations, urotropin and probably vaccines. The urologist also has numerous other faults to find with the management of patients whom he feels should have been treated differently or correctly diagnosed at an earlier date.

These fault-findings are not entirely just. If the patients whom a specialist should have seen, either in consultation or directly, are not brought to his attention at the preferred time, the fault lies with the specialist himself, and should feel rather acutely that he has been remiss in one of the principal debts he owes to the profession. The specialist has neglected to convey to his colleagues the cardinal indications for consultation. It may be argued that the indications are well known, that text books point out where specialized skill or knowledge should be made available. This plea is insufficient. One needs but to recall the fact that the volume of medical literature is very great, that the important is so closely interwoven with the relatively less important that not infrequently only the specialist himself can say what is vital and what is not.

What is needed is that the specialist be a propagandist—a special pleader—not for himself, nor his profession, but for humanity. Most of the writings of medical men are addressed to the group doing the same type of work as themselves. What is needed is that the specialist address himself to the profession, writing and speaking, not about the unusual, but about such commonplaces as stone in the bladder, stone in the kidney and tubercular kidney. His literature, addressed to the profession at large, should be instructive, warning of the dangers possibly lying back of a frequency of urination, of certain microscopic urinary findings, and so forth.

These articles should indulge in plain speaking. No harm can be done, and good will result from articles couched in terms of humanity, rather than in the somewhat less startling terms of science.

There are many reasons why men in general practice treat patients which in their very nature require special skill, and most of these reasons are not selfish. Consider that nearly every individual or family has an acquaintance with some medical man. The patient presents himself with frequency, because of pyurea or some other urological symptom. The matter may not be looked upon by the patient as being of particular importance. The physician, untrained in the significance of the symptoms, and through years of experience having reached the conclusion that the majority of human ailments are transitory anyway, hopes for a passing of the trouble, resorts to some innoxious palliative treatment. The patient who does not realize the difference between the significant and the trivial may insist upon con-

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

tinued treatment by the physician of his choice. The matter *may* be of practically no importance, and again it may be of the gravest importance. That the differentiation is not made is solely the fault of the specialist. The specialist should have impressed upon the profession at large the high lights of his specialty, as, for example, a manufacturer of automobiles impresses upon the general public the selling points of his machine.

Another obligation the specialist owes to the profession is to unmistakably convey the idea that the referred patient is at all times the patient of the medical man referring the case. At no time nor under any circumstances is the patient the specialist's patient, except for the condition pertaining to his specialty, and then only by the positively expressed wishes of the colleague who referred the case. If a case is sent to a specialist for examination, professional courtesy and even common decency demand that the patient, after an examination, be referred back to the original physician. Let it be the referring physician's right to suggest to the patient that he avail himself of the specialist's further services.

If a specialist is treating a patient and a member of his family consults the specialist, the patient should be directed to consult the physician through whom the specialist made his contact with the individual or family. That the specialist may consider someone else more competent, does not alter this conclusion. All specialists realize this and the majority adhere to our established ethics upon the point. However, I fear we have not made our stand in this matter absolutely clear and unmistakable to the profession at large.

We have dwelt somewhat upon our obligations, but, as in all affairs of life, these obligations are more or less reciprocal. What are the obligations of the internist and the surgeon to the specialist? To the specialist the general practitioner owes nothing except courtesy, but his duty to the public should oblige him to seek the specialist's assistance in those cases which in his heart he feels are not receiving from him the best that may be had.

The physician and the surgeon owe it to the patient and to themselves to take advantage of counsel with the urologist in every case of doubt. Suprarenal abscess, for example, may not uncommonly be diagnosed only after pyelograms. Diagnosis of ureteral calculi, renal calculi and even vesical calculi cannot be made with certainly without a urological examination. Kidney infections with colon bacilli, any of the cocci or bacillus tuberculosis, require and are entitled to receive a complete urological examination.

Your attention is invited to the interesting figures so ably presented by Dr. Cecil, regarding various kidney conditions erroneously diagnosed as something else. Out of a series of three hundred cases investigated, Cecil reported thirteen cases who went to operation for appendectomies, gall-bladder drainage and other abdominal conditions suspected but not demonstrated. He reports eight cases the diagnosis of which was erroneous but which did not go to operation; these mostly suspected appendicitis. A competent urological examination would have prevented these unfortunate mistakes.

From the surgeon's standpoint it is humiliating, and from the patient's point of view it is discouraging to be operated upon for a trouble not found to exist. It is such things that make patients doubt and distrust the profession. The surgeon has no right to damage the reputation of himself and his fellows by neglecting to avail himself of timely counsel. To the end that he may have no excuse that he does not know when this counsel should be sought, it is for the urologist to impress upon the whole profession the indisputable fact that pyurea, hematuria, and pains, whether of the presumably renal type or abdominal or gastric, should be, so nearly as is humanly possible, accounted for before resorting to surgery.

To the physician we must protest that vaccines alone are not an infallible cure for kidney infections, nor are they, unsupported by ureteral catheterization and lavage of kidney pelvis and ureter, ever to be depended upon as a sole therapeutic means. To the physician, also, we must protest emphatically that ureteral catheterization is *not* the cause of kidney infections, and that the physician who counsels against it with no better argument than this, reflects scant credit upon himself as not being conversant with the best of modern opinion supported by the results of research.

In closing, I repeat that the urologist and every other specialist as well has done much less than his duty to his profession and to the public when he fails to keep before the minds of his colleagues the things about which they must not waver.

BOSTON MEDICAL

A REPORT OF THE WORK OF THE RADIUM DEPARTMENT OF THE UNIVERSITY OF CALIFORNIA HOSPITAL, BETWEEN APRIL, 1920, AND APRIL, 1921.

By LAURENCE R. TAUSSIG, M. D., San Francisco,
Director of the Radium Laboratory of
the University of California

The purpose of this report is to place before the members of the medical profession a brief account of the policies and activities of the radium department during the year following the installation of a radium emanation plant at the University of California Hospital. In the early part of 1920 an order was placed by the University for an amount of radium sufficient to bring the total supply up to about 650 milligrams. At the same time a plant for the purification and tubing of the emanation was ordered. This plant was put in operation with a little over 600 milligrams of radium element in solution early in April and has been operating steadily ever since except for a few shutdowns to remedy minor breakages.

When the emanation plant was installed it was thought by a number of medical men that the supply of emanation would be practically unlimited and that it would make radioactive applicators available to anyone desiring them. This, of course, is not true. The amount of emanation on hand at any one time cannot exceed in activity the amount of radium in solution, and for a number of reasons, this maximum is never reached. It would be unwise to diminish the total amount available by the outright sale of any of the tubes. The Radium Committee decided that it should be applied only under the supervision of a member of the radium staff, in order, insofar as possible, to insure the best results. Clinic and ward patients, treated at hospitals affiliated with the University, are charged according to their circumstances. This charge is set by the social service department after appropriate investigation. Many of these patients receive treatment gratis. Private patients, either in the University Hospitals, or in other hospitals, are treated only in consultation with a member of the radium staff and are charged a definite fee according to the amount of emanation used. Private cases which are sent from medical men out of town are treated according to the indications as determined by any further examination deemed advisable and are referred back to the physicians sending them with suggestions for the after treatment as well as an account of the findings and methods of treatment employed. It is the policy of the department to answer inquiries from members of the profession as to the suitability of specific cases for radium therapy as definitely as possible. It is hoped that physicians, whether they possess radium of their own or not, will not hesitate to inquire about points in technique. Furthermore, visitors are always welcome to inspect any part of the work which interests them.

It is not the purpose of this report to go into the technique of the application of radium. In the future, as data accumulates and definite conclusions can be reached in the light of carefully kept records, papers will be published, detailing technique and results in specific groups of cases. At present the number of cases treated during the year will be given, with a general statement of the results obtained in each group. Insufficient time has elapsed to attempt to classify the end results because the majority of these cases are of malignancy.

Basal Celled Epithelioma—91 cases. The results in this type of malignancy continue to be eminently satisfactory. Radium therapy is especially satisfactory in the more difficult cases, particularly in those located at the canthi or on the lids of the eyes. The very extensive and long standing cases of this variety of epithelioma can also usually be improved if not cured.

Squamous Celled Epithelioma (of the glabrous skin)—20 cases. The primary lesion can usually be healed at least temporarily if not too extensive or if it has not been previously treated. Metastases in these cases are frequent and the end result in a given case is therefore in doubt for some time after finishing radium treatment.

Carcinoma of the Lip—15 cases. These cases have only recently been submitted to radium therapy. So far the results have been very encouraging. Radium should be combined with surgery and X-ray in many of them in preventing and in treating cervical metastases.

Carcinoma of the Mouth (exclusive of carcinoma of the tongue)—25 cases. When the lesion is not too extensive, a marked improvement can be obtained in some of these cases. The technique of treating mouth cases is changing and with the availability of the emanation the results have been improved.

Carcinoma of the Tongue—17 cases. Most of these were advanced cases. In the earlier cases the healing of the tongue lesion is the rule and even in late cases judicious therapy often effected considerable palliation. The main problem is the handling of metastases.

Carcinoma of the Oesophagus—5 cases. Improvement can be obtained in nearly all of these cases by the combination of the X-ray and radium therapy. This improvement consists in temporary relief of dysphagia, pain and cough with gain in weight and strength.

Carcinoma of the Cervix—38 cases. Radium is of benefit in all but very extensive cases and recurrences. Post-operative radium therapy has been abandoned.

Lymphosarcoma—7 cases. Radium in these cases is superior to X-ray only when the tonsils are involved or the growth is of limited extent. Temporary relief is usual, though recurrences generally occur.

Sarcoma—16 cases. Rapidly growing sarcomata react quickly to radium therapy, but recurrence follows a brief period of quiescence in most of them.

Keloid—4 cases. All but long standing cases can be greatly benefited.

Keratosis of the Lip—8 cases. These are potential carcinomata and should be treated as very superficial malignancy. Radium has proven very satisfactory.

Lupus Erythematosus—10 cases. In the chronic discoid type of this disease radium is often of considerable benefit.

Lupus Vulgaris—5 cases. No other form of therapy surpasses radium in treating even extensive and long standing cases of this disease.

Vascular Nevus—19 cases. In the raised type a good cosmetic result is the rule, but in the flat port wine stain type a slight paling is all that can be hoped for.

Verrucæ—5 cases. In certain regions radium is the treatment of choice. This applies particularly to those near the finger nail and to verruca plantaris between the toes.

Grave's Disease—11 cases. The result is earlier and more marked than in any other form of therapy. Whether the effect is permanent or not cannot yet be stated. Radium is not suitable in treating toxic adenomas.

Incipient Cataracts—60 cases. A large percentage of these have been given improved vision. Radium is useless in mature cataracts.

Miscellaneous—56 cases. This includes the cases which do not fall into any of the above groups, and in which the treatment with radium has been more or less experimental.

Thus 420 cases of various types have been treated during the year and though many of them are of the most hopeless in the realm of medicine, the results have been encouraging. New fields are being opened to radiotherapy by changing methods and improvements in technique are leading to better results. The use of the emanation instead of radium element has proven eminently satisfactory. The advantages far outweigh the few disadvantages and make the use of emanation preferable.

Hotels as Doctors of Nutrition—Press dispatches are making much of the entrance of hotels, cafeterias, restaurants and similar places into the practice of medicine. The "scientific diet service" is now a feature of a number of prominent hotels. All one is required to do is to look down the special menu, pick out his own diagnosis and, presto, the proper diet for that disease is available! Some of the Eastern cities also now have "healtheterias," devoting themselves exclusively to the "scientific feeding of the undernourished" and those suffering from chronic diseases. Many of them are paying particular attention to the undernutrition of children as a specialty. Some of them advertise their expert medical advice in electric-light signs at night.

With the statistics by "food specialists" showing that the majority of our people, and particularly of our children, are undernourished and suffering from various grades of starvation, these scientific (?) nutrition institutes ought to do a flourishing business during the ephemeral existence of this particular and exceedingly foolish fad.

STRICTURE OF THE URETHRA IN WOMEN *

By WILLIAM E. STEVENS, M. D., San Francisco.
From the Urological Department of the Women's Clinic, Stanford University Medical Department, and the San Francisco Polyclinic.

Stricture of the urethra in women is a condition which is very often overlooked, although it may be responsible for marked functional and organic disturbances in the genito-urinary tract of this sex. While the kidneys, ureters and bladder are usually carefully investigated in the presence of symptoms referable to the genito-urinary tract, examination of the urethra is frequently omitted, and consequently pathological lesions of this important organ are neglected.

This is probably due to the generally accepted idea that strictures of the female urethra are very uncommon. While this is true so far as the lumen of the canal is concerned, strictures at the meatus on the other hand are frequently encountered.

Dilatation of the urethra has long been an empirical treatment for urinary disturbances and every urologist has noticed the marked symptomatic improvement that sometimes follows the single introduction of a cystoscope or ureteral catheter. Impressed by the frequency with which this occurred, I decided to examine the urethra more thoroughly, and consequently, in addition to endoscopy, have made it a practice to calibrate this organ in all women, as well as in men, who complain of urinary symptoms. Including strictures of the meatus, which are much more numerous than those in the lumen of the canal, the results were most interesting, the number far exceeding expectations.

In reviewing the literature, I found that many years ago, Skene, in his interesting book on "Diseases of the Bladder and Urethra in Women" said, "the form of stricture that will most often come under your consideration will be a contraction of the meatus urinarius, produced in many cases by too liberal use of caustics in the treatment of abnormal growths at the lower end of the urethra, or from vulvitis." The vulvitis to which he refers was probably gonorrheal in origin for, as we now know, the urethra is involved in almost all cases of this infection.

A few years later at the forty-first annual meeting of the American Medical Association, Van de Warker, in calling attention to strictures of the urethra in women said, "the form of stricture I have most frequently met with, and one that produces the most acute symptoms, is the annular stricture of the meatus." With the exception of the latter's paper in 1890, I have been able to find but one important contribution to this subject, that of Maurice Vilfroys in 1914, since it was first mentioned by Lisfranc about one hundred years ago.

Heinrichsdorff recently reported a case in which death occurred, following catheterization of the bladder in a woman sixty-five years of age who had complained of involuntary dribbling of urine

---

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

and difficult urination for one year. Necropsy revealed that the urethra in its proximal third was so constricted that only small sounds could be passed. The wall of the neck of the bladder was hard and much thickened. The bladder itself was extremely large, the wall was stiff, and in places a centimeter thick. In some places the bladder wall was thin and protruded outward. Both ureters were thick as a finger, tortuous and filled with a purulent fluid. The kidneys were enlarged and very soft, studded with small abscesses, very little normal tissue remaining. The condition was thus due to stenosis of the upper urethra, which had entailed retention and stagnation of urine and dilatation of the superior urinary passages, followed by their infection and a suppurative process throughout the kidneys.

Herman, of London, following the examination of fifty-five women without urinary symptoms, concluded that the normal size of the female urethra is F 29, a little less than ten millimeters. Van de Warker expressed the opinion that a urethra from F 23 to F 28 should be considered normal. Examination of 114 patients at the Stanford Women's Clinic disclosed the fact that only 18 or about 16 per cent had never suffered from symptoms referable to the urinary tract. Following urethral calibration in these eighteen cases, I found the average size of their urethra to be F 26 or a little less than nine millimeters. My opinion is that a urethra below this size is usually abnormal, and the response to treatment has justified this conclusion. In the series of pathological cases upon which my observations have been based, the average size of the stricture was F 22. The smallest would not admit a filiform.

The youngest patient was three, and the oldest sixty-nine years of age, the average being forty-four years.

My patients have been divided into three classes, prostitutes confined in a special ward at the San Francisco County Hospital, clinic patients seen at the Stanford Women's Clinic, Mount Zion Hospital Clinic and San Francisco Polyclinic and private patients. As practically all of the first class had at some time suffered from gonorrhea, the significance of this infection as a factor in the etiology of strictures could be determined. In fact, the meatal strictures occurring in prostitutes exceeded that found in clinic patients by eleven per cent, and in private patients by twenty per cent. It is, therefore, apparent that Neisser infection is the most important etiological factor in strictures occurring at or just within the meatus. Other causes of obstruction at this location are congenital malformation, contraction following the traumatism resulting from childbirth, ulceration, caustic applications and operative procedures. I have not been able to satisfy myself that focal infections, as suggested by Hunner, have any bearing upon the etiology of this condition. Strictures of the lumen of the canal, which are usually due to traumatism associated with childbirth, are as infrequent in prostitutes as in other classes of patients. This is to be expected, as the female urethra, with the exception of its few ducts and glands, is, like the membranous portion of the male urethra, lined with squamous epithelium, and consequently resistant to all forms of infection.

COMPLICATIONS

Hunner found urethral stricture in eighty-five per cent of his patients suffering from stricture of the ureter. From the fact that most of our cases cleared up under local treatment of the urethra, the conclusion is drawn that the majority of urethral strictures on the other hand, are not complicated by stricture of the ureter. A note should be made, however, of the fact that two of our youngest patients, girls eight years of age, suffered from both ureteral and urethral strictures.

The most frequent complications are urethritis and trigonitis, and one or both of these conditions were present in eighty-three per cent of the cases in this series. The fact has long been recognized that stricture or obstruction from any cause predisposes to infection higher up in the urinary tract. Pus was found in eighty-five per cent of the catheterized specimens of bladder urine in these cases.

SYMPTOMS

As the female bladder is especially sensitive to reflex influences, marked subjective symptoms are often produced by comparatively slight obstructions. It must be remembered, however, that these symptoms may be partly due to the accompanying urethritis or trigonitis.

Frequent urination is the most common symptom of which these patients complain. It was seldom absent, occurring in over eighty-five per cent of our clinic and private cases. Subjective symptomatology was not taken into consideration in the patients confined in the detention ward of the San Francisco Hospital, as many of these deny disability, hoping to be released as soon as possible.

Next to frequent urination, these patients most often complain of pain, which is referred to the urethral or bladder regions. This symptom occurred in sixty-four per cent of our cases. Burning or smarting was present in twenty-six per cent, urgency in five per cent, and difficulty, constant desire to urinate, partial incontinence, dribbling and retention of urine, were each present in two and a half per cent of our patients. Residual urine is seldom found except in the presence of very tight strictures.

DIAGNOSIS

The diagnosis of stricture is best made by means of the olive-tipped bougie. A urethrotome, or sound, is much less reliable, as strictures of the female urethra usually yield readily to slight pressure, and consequently higher readings result from use of the latter instruments.

TREATMENT

The majority of urethral strictures should be treated by means of gradual dilatation, absorption of the constricting exudate being best promoted by this procedure. In the presence of scar tissue, however, meatotomy, internal urethrotomy or external urethrotomy with resection of

this scar tissue is often indicated. Using the French scale of measurement, a straight sound of the same size as the stricture is introduced. The sounds are increased two numbers at each treatment until an F 30 passes without difficulty. Following the withdrawal of the sound a few cc. of one to three per cent silver nitrate solution are injected into the bladder and urethra. At first treatments are given twice a week, but the interval is gradually lengthened to once a month and then may be discontinued. Preceding dilatation the use of a local anæsthetic such as a ten per cent cocaine solution on a cotton-tipped applicator is sometimes advisable in nervous women.

The symptoms improve, as a rule, after two and disappear after five dilatations, recurrence being very unusual if treatment is not too abruptly discontinued.

The following brief case histories, two of stricture at the urethral meati, and the other of both the lumen of the canal and the meatus are typical of many which have come under my observation.

Case I.—Married woman, age fifty-two, housewife, nullipara, complains of frequent urination, that the urine escapes slowly and that dribbling is usually present. The symptoms began three months ago and are gradually increasing in severity. She denies Neisser infection and gives no history of previous genito-urinary symptoms. A catheterized specimen of bladder urine contains an occasional pus cell. The olive-tipped bougie encounters a stricture, F 20 in size, at the external urethral meatus. Following two treatments which consisted of dilatation with straight urethral sounds, followed by the instillation of one per cent silver nitrate solution the symptoms had markedly improved. The symptoms disappeared after the third treatment.

Case II.—Married woman, forty-five years of age, housewife, the mother of nine children, complains of burning in the urethra, worse at the beginning of urination, and nocturia. Her past history and family history are of no significance.

The present illness began shortly after her first confinement twenty-one years ago with burning, stabbing pain worse at the beginning of urination. She has had attacks of difficult urination, at which times the urine escaped drop by drop. The symptoms have been worse since her eighth confinement nine years ago. Ten months ago she suffered from retention of urine for three days. She was taken to the hospital, where a growth was removed from the meatus and the urethra dilated with sounds at intervals for one month. All symptoms except the burning sensation disappeared and she did not come to the clinic for further treatment as requested. Three days ago micturation again became difficult, the urine escaping in drops. She states that some relief was obtained in a few hours by the application of hot compresses to the vulva.

Examination disclosed a stricture just inside the meatus through which an F 12 glass catheter could be introduced with difficulty, and another stricture of slightly larger caliber in the posterior third of the urethra. Scar tissue resulting from childbirth was responsible for both strictures. Residual urine amounting to 60 cc. was present. Because of the nature of the obstruction, the small caliber of the strictures and the pain caused by instrumentation, meatotomy and internal urethrotomy were deemed advisable. All symptoms disappeared following these operations.

Case III.—Female child, three years of age, complains of frequent urination and pain in the region of the bladder of one month's duration.

A number five ureteral catheter was passed with difficulty because of a stricture at the external urethral meatus. The catheterized specimen of bladder urine contained a few pus cells. Culture showed non-hemolytic streptococci. The symptoms improved after the second and disappeared after the fourth dilatation of the urethra.

CONCLUSIONS

Stricture of the female urethra is relatively common, and consequently calibration of this organ should be a part of the urological examination of every woman and child complaining of symptoms referable to the genito-urinary tract.

Strictures of the female urethra respond readily to proper treatment, and their early detection will prevent pathological lesions of the upper urinary tract secondary to this condition.

(210 Post St.)

PRE-ATAXIC GASTRIC CRISES OF TABES *

By CLYDE FISHBAUGH, A. M., M. D., Los Angeles, Cal.

Because of the frequent mistakes in diagnoses and numerous unnecessary operations on patients with pre-ataxic gastric crises, it seems opportune to present this subject at this time. Neurologists are alive to the frequency of this condition and, doubtlessly, fail to recognize very few cases, but physicians and surgeons have all found early stomach crises an easy pitfall.

Nuzum,[1] in a review of one thousand patients at the Cook County Hospital, Chicago, noted that visceral crises of tabes was observed in 22 per cent of the cases. Of the 22 per cent, 19 per cent were of the gastric type, 2 per cent renal, and 1 per cent intestinal. Erb[2] found visceral crises ten times in 400 cases, and Fournier,[3] fifteen times in 210 cases.

In reports of these large groups of cases, the pre-ataxic have not been differentiated from the ataxic form. It is the purpose of this communication to consider only that form of gastric crises noted in pre-ataxic patients. The diagnosis is easy in ataxic patients, as other features of tabes are in evidence. The frequency of incorrect diagnosis of gastric crises in all stages of tabes is emphasized by Nuzum,[1] who observed that 87 per cent of the 220 patients had been operated upon unnecessarily. Of this number, eighteen were operated upon for gastric ulcer, sixteen for gall stones or cholecystitis, seventeen for appendicitis, eleven for prostatitis, six for renal colic, five for post-operative adhesions, one each for cauda equina, meningocele, ectopic gestation, peritonitis, and nine operations were exploratory.

The following cases illustrate the great diversity of symptoms, findings and diagnoses encountered in the study of this manifestation of spinal syphilis.

Case No. 1.—An actor, 38 years old, complaining of stomach trouble. About fifteen years ago the patient began to have very severe, dull, heavy pain in the abdomen. Pain would come on during

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

on right after a meal, and was not accompanied by nausea or vomiting. The attacks would last from one-half to one hour and then gradually wear away. There has never been any special soreness in his abdomen. Occasionally he would be completely free of symptoms two or three years. All of a sudden the trouble would return and the attacks would continue daily for three, four or five years. The last series of attacks started two years ago. Pain frequent after dinner; rare after breakfast or luncheon. Pain has been so severe at times that he has required an opiate for relief. He has never awakened in the night with pain. Recently has vomited food eaten a short time before, but vomitus contained no blood.

Complains of slight dryness in his nose, and at times a slight hacking cough. The appetite has been poor for five or six years. Bowels usually constipated. Has been married thirteen years. Wife in good health; no pregnancies. There is history of a chancre seventeen years ago, followed two or three months later by a rash and ulcers in his mouth. Following the rash the skin pealed off the palms and the soles. He was treated with mercury and iodide for about one year. His weight was 154 in 1900, and is now 127 pounds.

Physical Examination.—Rather poorly nourished man; pupils slightly irregular, react slowly to light, but actively to accommodation. The palpable lymphatics are small and shotty. No abnormalities found in special examination or laboratory tests of the heart, lungs, abdomen, rectum, tonsory system, urine, blood, feces or reflexes.

The Wassermann reaction was negative from the blood, but very strongly positive from the spinal fluid.

Case II.—Moving picture actor, age 38, weighing 252 pounds, complains of pain in the pit of the stomach and vomiting. About fifteen years ago he had severe gripping pain in the pit of his stomach, which came on suddenly and was continuous for two weeks. There was no nausea or vomiting. There was soreness on pressure. Since that time the patient has had repeated attacks of similar nature lasting ten to fourteen days. There have been intervals of several months' freedom between attacks on numerous occasions. He had been free from attacks for two years until three days ago, when he had an exceedingly severe pain, not relieved by food. He has vomited green, sour chyme many times daily since the onset. Black stools have not been noticed, and sodium bicarbonate causes him to belch, but does not relieve the pain. He has awakened at night with the pain. Bowels are regular.

The patient has been married for eight years. Wife is living and well, and has not been pregnant.

Physical Examination.—The pupils are slightly irregular in outline, but reacted sluggishly to light and actively to accommodation. There is a rather marked tenderness three or four inches above the umbilicus in the median line. The knee kicks are rather sluggish. Rhomberg negative. No abnormalities are found by physical examination or laboratory tests of the sensory system, gastro intestinal, or urine. Wassermann reaction of blood showed a single plus and the spinal fluid gave a four plus.

Case III.—Mechanic, age 34, complains of pain in the abdomen, nausea and vomiting. The patient was perfectly well and strong until six years ago, when after having a bowel movement, was taken with very severe pain in the upper part of his abdomen, followed by nausea and vomiting. A physician was called, who stated that he was having an attack of gall stones. The following day operation was performed, but no gall stones found. Shortly after his return from the hospital he had another attack similar to the one above described. The patient has always associated these attacks with overeating or too much laxative. The attacks last for a day or two and are followed by a few days of rest. Another physician diagnosed his condition as chronic appendicitis. The appendix was removed, but the attacks continued to occur as frequently as previously. Some years later a surgeon performed an exploratory coelectomy, but found nothing wrong. Since the last operation, has had attacks at varying intervals, from a few days to a few weeks. For the last two weeks the attacks have been of daily occurrence, usually coming in the after part of the day, so severe that morphine was necessary for relief. The pain starts in the pit of the stomach, and is soon followed by violent vomiting which continues until relieved by an opiate. At times he has vomited black blood, but has never had black stools. Following the first operation, the patient was given some medicine by mouth for the pain. After taking it a short time he noted that his pupils were dilated, one of which never contracted to normal. The left has remained somewhat larger than the right.

The patient has been married for three months. He had gonorrhoea fifteen years ago which was cured in a week's time. He gives a negative history of syphylis.

Physical Examination.—Fairly well nourished man, about twenty pounds under weight. The pupils are irregular in size and shape. Both react slightly to light and promptly to accommodation; eyegrounds were negative. There is slight tenderness in the epigastrium, otherwise the abdomen is negative. Rhomberg sign is negative; patient reflex positive on re-enforcement; urine, negative; blood, negative; stool, normal; Rehfuss test breakfast, normal; X-ray examination said to be normal; and sensory examination normal; Wassermann test, blood one plus. Spinal fluid four plus.

Case IV.—Man, age 42, complains of pain in the stomach and vomiting. Four years ago patient suffered from exceedingly severe pain in the pit of the stomach, shooting upwards to the shoulder. The pain did not radiate to the back. At the onset, vomited bile with each attack of pain. The first attack lasted one month or so. He felt good for two or three months and then had another attack. The pain came without any apparent warning and left rather suddenly. Vomiting was followed by slight, temporary relief. Food did not relieve the pain. While being observed in a hospital, he vomited blood repeatedly and on October 22, 1916, gastro enterostomy was performed for a mistaken diagnosis of ulcer of the stomach. Soon after leaving the hospital he had another attack. One year later the patient consulted another surgeon, who removed the gall bladder and later the appendix with no apparent benefit. The patient returned to work and would work a month or so and then be compelled to stop for a few weeks because of an attack. The last attack started three weeks ago. He has very severe pain in the abdomen, chest and across the shoulder blade. Anything he eats is vomited in ten or fifteen minutes, bitter and yellow. He has soreness in his abdomen. The pain is a sharp, gnawing pain, never stopping. Massage of the stomach gives no relief. Baking soda affords some relief. Bowels have always been regular.

The patient has a wife and four children, all living and well. Syphilis and gonorrhoea are denied, and the wife has had no miscarriages.

Physical Examination.—The patient is fourteen pounds under weight. The pupils are slightly irregular and react sluggishly to light, but actively to distance. There is slight tenderness over the entire abdomen, more marked in the epigastrium. The knee kicks are obtained on re-enforcement; Rhomberg reflex, normal; sensory examination, negative; blood count, normal; and urine, normal. The Ewald test breakfast shows free hydrochloric acid 16 and a total acidity of 28 per cent; no occult blood, but bile positive. The X-ray exami-

nation, by a very competent roentgenologist, reveals no stomach abnormality. The Wassermann test from blood one plus; from spinal fluid four plus.

SUMMARY

These patients presented many similar features, which were helpful in diagnosis.

1. Weakly positive Wassermann in blood, but strongly positive in the spinal fluid.
2. Irregular pupils.
3. Reaction of pupils to light sluggish, reaction to accommodation normal.
4. Normal or sluggish knee kicks. Rhomberg and sensory examinations negative.
5. Sudden onset and sudden relief from attacks, without apparent cause.
6. Violent pains without food or alkali relief.
7. Severe vomiting during paroxysms with occasional hematemesis.
8. Absence of fever during attacks.
9. Normal urine, blood, test breakfast, and gastro-intestinal X-ray examinations.

Gastric crises are often the first symptoms of locomotor ataxia and may remain so for years. Two of these cases had had definite stomach crises for fifteen years, one for six years and the other for four years, and none had shown ataxic signs.

Charco, in his classic description of tabes in 1868, recognized the diagnostic pitfalls of this manifestation of syphylis when he said, "but of all the visceral symptoms, one which is most remarkable and the least known, if I mistake not, is that which I have proposed to designate by the name of gastric crises."

In conclusion it should be emphasized, that until the symptoms of gastric crises is kept constantly in mind, and until the Wassermann test becomes routine in chronic abdominal complaints, spinal syphylis will continue to be mistaken for real abdominal pathology.

GASTROENTEROPTOSIS.*

By HENRY L. HAYES, P. A. Surgeon (R),
Gastroenterologist, U. S. P. H. S. Hospital No. 21,
Palo Alto, California.

DEFINITION—Gastroptosis, which in its strict and narrow conception indicates ptosis of the stomach, was first described by Glenard, and we are indebted to him for the introduction of the term to medical nomenclature. The condition of ptosis of the stomach alone, however, occurs so infrequently and is so commonly associated with ptosis of the other abdominal organs that the more comprehensive term of Gastroenteroptosis has superseded the more restricted term. Prolapse of the kidneys, intestines, colon, spleen, liver, etc., are indicated by the terms nephroptosis, enteroptosis, coloptosis, splenoptosis, hepatoptosis, etc., but, like prolapse of the stomach, they occur singly so infrequently that it seems wiser to discard this cumbersome and unnecessary multiplication of terms and adopt the all-embracing term of Gastroenteroptosis.

ETIOLOGY—Prolapse of the abdominal organs is frequently met with in patients who consult the physician for some gastric disturbance and who attribute their symptoms to some organic or functional disease of the stomach. The diagnosis made by the patient is frequently "dyspepsia," "gastritis" or "gastric ulcer," and it is only when such patients are subjected to more careful observation and study that the true condition is revealed.

Etiologically two different forms of gastroenteroptosis are found, the first being acquired and the second inherited. The first type is found as a result of mechanical causes, chief of which are improper dress in women, traumatism and frequent child-bearing followed by improper post-partum care. One of the most frequent and potent causes is lowering of the intra-abdominal pressure from the emptying of the uterus, the removal of large abdominal tumors or cysts and the draining of ascitic fluid. To these factors in the lowering of the intra-abdominal pressure may be added loss of weight, and particularly loss of omental fat, which frequently follows wasting disease, and by which the natural fat cushion which bolsters up the viscera and aids in maintaining the intra-abdominal pressure is lost.

The inherited or constitutional form of gastroenteroptosis has been especially brought to the attention of the medical profession by the researches of Stiller. According to this investigator 90 per cent of the cases of prolapse of the abdominal organs owe their abnormality to a distinct form of physical conformation which he designates as the "habitus enteroptoticus." Patients exhibiting the "habitus enteroptoticus" and suffering from the weakness and malpositions of the abdominal organs which accompany it are apt to develop into neurasthenics.

The attitude of the patient is probably the first thing that will attract the attention of the physician in those showing the characteristic "habitus enteroptoticus." Such patients do not stand erect, but slump down in a characteristic attitude, —stooped shoulders, retraction of the epigastrium

* Read before the San Bernardino County Medical Society at Arrowhead Springs, California, April 5, 1921.

and protuberance of the hypogastrium, forming the so-called "pot belly." Such patients will usually exhibit a general lack of muscle tone; they are weak and have long, narrow chests with a rather acute costal angle. Frequently, also, they will show a floating tenth rib (Stiller's sign). This is the type of patients in whom we are accustomed to look for floating or prolapsed kidney, and the finding of this stigmata, combined with a low-hanging stomach, is almost pathognomonic of gastroenteroptosis.

Associated with prolapse of the stomach and intestines we almost always find gastric and intestinal atony, defective or irregular gastric secretion and nervous dyspepsia. These three disorders may differ in degree and in their relative severity; at one time the symptoms of the prolapse will predominate; at another time the gastric secretion will be at fault; and again the outstanding symptom will be the nervous dyspepsia.

Pathology—By the term gastroptosis we do not imply a prolapse of the entire stomach. Owing to the attachment of the stomach at the cardia it is impossible for the entire organ to descend. What is meant by the term is a prolapse of the pyloric end of the stomach which implies a stretching, or downward drag, of the organ, forming the so-called "water trap" stomach. The causes leading to this descent of the stomach and intestine is probably a stretching or relaxation of the mesentery and ligaments due to deficient muscle tone which is inherent in the "habitus enteroptoticus" and also to the disturbance of the equilibrium of the intra-abdominal pressure due to the loss of mesenteric fat, the emptying of a gravid uterus or the draining of ascitic fluid.

In any marked ptosis of the stomach the duodenum, in whole or in part, is dragged down with it, and the entire large intestine is pushed down by the descending stomach. The mesentery stretches easily to meet this condition. Only at the hepatic and splenic flexures of the colon do the mesenteric supports rigidly hold the organ in place, and as a consequence a sharp angulation of the gut occurs at both of these points. Not infrequently, however, a downward displacement of the liver will occur in connection with the ptosis of the other abdominal organs, and in such cases marked angulation of the colon at the hepatic flexure will not be found. The hepatic flexure is normally somewhat obtuse, and the angulation at this point caused by prolapse of the colon is rarely marked. The splenic flexure, on the other hand, is normally acute, and when accentuated by prolapse of the transverse portion of the colon may produce a condition approximating stenosis. This produces a mechanical obstruction to the passage of the intestinal contents, and, in connection with the atonic condition of the stomach and intestines inherent in the "habitus enteroptoticus," leads to an obstinate obstipation, which is characteristic of gastroenteroptosis. Because of the festoon-like position of the transverse colon the contents of the colon have to be propelled "up hill," so to speak, to encounter the obstruction offered by the sharp angulation of the splenic flexure, and the atonic musculature of the bowel is unequal to the task of propelling the fecal contents past the obstruction.

The transverse colon is the portion of the intestine most frequent, and most markedly, involved in prolapse of the stomach, though the entire gut is usually pushed downward by the weight of the superimposed organs and the weakening of the mesenteric supports. Any material degree of gastroptosis will produce coloptosis and enteroptosis. In women it is not unusual to find prolapse of the uterus and ovaries associated with prolapse of the stomach and intestines, since the same causes operate in one case as in the other.

Incidence, Age and Sex—Kemp, in his work on Diseases of the Stomach, Intestines and Pancreas, quotes Meynert as having found in fifty girls, twelve years of age, 50 per cent with gastroptosis, while 80 per cent of all the women in his gynecologic clinic were said to present this condition. The percentage of cases occurring among male adults he places at five. Kemp says, further, that from a study of various statistics it may be estimated that from 20 to 25 per cent of women complaining of gastric disturbances will be found to have movable kidney and enteroptisis, and that unquestionably the percentage of cases of gastroptosis among all women, including those who complain of no symptoms whatever, will average at least 15 per cent in our city populations. The percentage of cases of enteroptisis and nephroptosis among males complaining of gastric symptoms Kemp places at about two or three. He finds the ratio of men to women to be as 1 to 8 or 10. Glenard finds a higher percentage in both men and women, and his figures for incidence in both sexes is 30 per cent and 70 per cent, respectively, for men and women, the ratio between the two being 3 to 7.

The age at which the syndrome is most frequently noted is between 18 and 40, though, as Meynert has stated, he has found the condition in 50 per cent of girls 12 years of age. Between 50 and 60 years of age the symptoms of the condition are more manifest than at an earlier age, as would naturally be expected in view of the decreased muscular tonus of the abdominal walls which accompanies advancing age.

Subjective Symptoms—The subjective symptoms of gastroenteroptosis are generally those of neurasthenia plus those of gastro-intestinal disturbance. At times there may be a total lack of symptoms and the condition is discovered by accident or in the course of an examination for some other condition. When symptoms exist they may be referable to the stomach, intestine, gall bladder, kidneys or appendix. The symptoms may vary in degree from slight discomfort to the severe type described by Glenard. The picture given by Kemp of the gastroenteroptotic patient is as follows: "Some patients have the symptom complex of hyperchlorhydria, while others complain of belching and discomfort immediately after meals. There is usually marked and obstinate constipation; rarely diarrhoea. At times intestinal catarrh or mucous colic is noted, and flatulence is often complained of. The patients may suffer from headache, are frequently nervous and hys-

teric, almost always neurasthenic, irritable and mentally depressed. There is often a feeling of weight or bearing down in the abdomen which is relieved by proper support. In women menstrual disorders are frequent and dysmenorrhoea is often present."

According to Aaron, patients with the "habitus enteroptoticus," which has developed into pronounced gastroenteroptosis, may not experience any troublesome symptoms whatever from their misplaced organs. The same may be said of those whose prolapsed abdominal organs are the result of purely mechanical processes, and many patients with gastro-enteroptosis have been relieved of their distressing symptoms without the correction of their anatomic displacements. From these facts it may be inferred that gastroenteroptosis alone, in many cases, is not responsible for the invalidism of the patients, but that the cause must be sought for in the triple symptom complex of gastroenteroptosis, atony of the gastro-intestinal tract and neurasthenia. As Aaron very tersely expresses it: "The constitutional neurasthenia of enteroptotics is responsible for a great many of the subjective symptoms ascribed to gastroenteroptosis itself. The displacement merely aggravates the neurasthenic effects, or perhaps in some instances initiates them by the continuous traction of the displaced viscera on the mesenteries, thus placing the abdominal sympathetic nervous system in a condition of continued reflex irritation."

The general weakened muscular tone of the patient suffering from gastroenteroptosis manifests itself especially in the gastro-intestinal tract, and as a result we have atony of the stomach and intestines. This condition, with the concomitant neurasthenia, induces such symptoms of nervous dyspepsia as pressure, fullness, nausea, belching, burning sensation in the stomach, hyperacidity, vague discomfort after eating and occasionally pain in the epigastric region. Accompanying these symptoms there may be a variety of nervous manifestations, such as lassitude, dull headache, inability to work or to concentrate, irritability, mental depression and general weakness. As a rule the appetite is poor, though occasionally it may be normal or, more rarely, voracious. A frequent symptom, especially in women, is backache, which, in their case, may be due to prolapse of the uterus or ovaries which so often accompany descent of the abdominal organs.

Objective Symptoms—Patients with the "habitus enteroptoticus" present a characteristic appearance. As a rule they are tall and thin, or of slight stature, with long arms, thin neck, narrow thorax with acute costal angle. They stand in a slouching position, with sloping shoulders, retraction of the epigastric region and a protuberant abdomen,—the so-called "pot belly." The bony structure is slight, the muscles weak, there is a marked diminution of adipose tissue and there is a predisposition to lordosis and flat-foot. Stiller gives as one of the stigmata of the "habitus enteroptoticus" a floating tenth rib. These patients often suffer from anaemia, look pale and give the impression of being ill.

The X-ray affords very valuable aid in the diagnosis of gastroenteroptosis. The ptosed stomach is seen to be elongated, of the fish-hook or water-trap form, with the upper border below the level of the umbilicus. An abnormally low position of the greater curvature of the stomach cannot be taken as evidence of ptosis, as this occurs in dilatation of the stomach as well as in ptosis of that organ. To constitute prolapse of the stomach there must be a descent of the lesser curvature as well as of the greater. Associated with the characteristic elongated form and low-hanging position of the stomach the X-ray will also frequently show a sluggish motility and inefficient peristaltic waves. The gastric atony thus shown by X-ray examination need not necessarily result in gastric retention, as evidenced by the presence of barium in the stomach after six hours, for the gastric atony may be compensated for by a relaxed pylorus and the stomach may empty itself in normal time despite the deficient motility.

In order to demonstrate the co-existence of coloptosis or enteroptosis with the gastroptosis it is advisable to administer a barium enema and examine the patient in the standing position, or, if the enema is not feasible, almost equally good results may be obtained by an X-ray examination of the patient in the standing position twenty-four hours after the administration of the barium meal. The transverse colon will then usually be found to form a low-hanging loop, or festoon, between the hepatic and splenic flexures, the lower portion often lying on the floor of the pelvis.

Diagnosis—The diagnosis of gastroenteroptosis is made on the history of the case, the gastric symptoms, the existence of a neurasthenic state, the "habitus enteroptoticus" and the X-ray findings. This symptom complex presents a picture which cannot easily be mistaken, yet it is no uncommon thing to find these patients being treated for gastric ulcer, gastritis, neurasthenia or constipation, without considering the syndrome as a whole. The diagnosis may safely be made on two physical findings alone, viz: a ptosed or movable right kidney and prolapse of the lesser curvature of the stomach below the level of the umbilicus. These two symptoms, when found in conjunction, may be said to be pathognomonic of gastroenteroptosis, though an X-ray examination of the entire gastro-intestinal tract should be made for the purpose of confirmation. I do not consider a gastric analysis essential for the diagnosis of gastroenteroptosis, as the findings are too variable to be of value. The secretion may be normal, hyperacid or hypoacid, and this variation may be found in the same individual at successive examinations.

Prognosis—The prognosis for total and permanent replacement of the prolapsed organs is not good. If the condition has existed for some time the ligaments and mesenteries will have become stretched, and it is impossible to restore them to their normal condition. It is possible, in some instances, to lessen the degree of the prolapse, but total replacement cannot be looked for. As has already been stated, however, the distressing symptoms which mark this symptom complex cannot

be attributed to the prolapse of the stomach and intestines alone, but have their origin in the general state of the patient, and it is possible to so improve this that the symptoms will wholly disappear, or be greatly ameliorated, and the patient enabled to live out the remainder of his life in comparative comfort. As Aaron has so aptly said: "We cannot give these patients normal mesenteries, but we may give them normal function."

Prophylaxis—The early recognition of the "habitus enteroptoticus" in young subjects should be sought by noting their peculiar physique and tendency to gastric disorders. In such patients marked departure from the normal and the development of pronounced gastroenteroptosis may be prevented by early and judicious hygienic and dietetic treatment.

In the case of parturient women with a tendency to gastroenteroptosis, rest in bed for a suitable time after confinement should be insisted upon, together with proper bandaging and the strengthening of the abdominal muscles by exercise and massage. Remembering that one of the most potent causes of gastroenteroptosis in those predisposed to the condition is the sudden letting down of the intra-abdominal pressure the importance of these precautions will be apparent. By the application of these prophylactic measures the undue relaxation of the abdominal walls incident to childbirth may be obviated and the necessary intra-abdominal pressure preserved. The same precautions should be observed in tapping the abdomen in cases of ascites and the removal of large abdominal tumors.

Treatment—The treatment of gastroenteroptosis, after the condition has been fully established, resolves itself into medicinal, dietetic, hydro- and physio-therapeutic, suggestive and mechanical. All other methods should be tried before recourse is had to mechanical measures, which at best afford merely an artificial support, or "crutch," to the weakened abdominal walls. These are sometimes justified and necessary, however, when other curative measures have failed or appear hopeless, and consist of some form of abdominal bandage which will raise the prolapsed viscera to a more normal position, prevent their further descent and maintain the intra-abdominal pressure.

Medicinal treatment consists in the administration of drugs which will improve the muscular tone of the stomach and intestines, overcome the atony of these structures, relieve the marked obstipation, promote the appetite, aid in the assimilation of food, relieve the neurasthenic state, assure sufficient sleep and build up the general well-being of the patient.

Hydro-therapeutics and physio-therapeutics should be of such a nature as will stimulate the muscle tone of the patient rather than depress it. Such measures are the alternating hot and cold shower, the needle spray, the Scotch douche, the use of the high frequency electric current and massage. Cabinet baths and hot tub baths are debilitating and should be avoided.

Since in gastroenteroptosis there is always a loss of adipose tissue and especially of the intra-abdominal fat, one of the first aims of the physician in treating this condition should be to increase the weight of the patient. The dietetic treatment of these cases has for its object the restoration of the patient to his normal, or supra-normal, weight and the improvement of the general nutrition in order to overcome the neurasthenic state, to strengthen the muscles of the abdominal wall and bring about the re-establishment of the intra-abdominal pressure. The diet should be as nutritious as possible, should be easily assimilated and should contain a large amount of fat. Milk, cream and butter are among the most suitable articles of diet, though the menu must be governed entirely by the requirements of the individual case, and the motor and secretory powers of the stomach and intestines must be given due consideration in prescribing the diet. These patients are always underweight, and it may be necessary to place them upon a rest-and-fattening cure in order to bring them back to, or above, the normal weight. It has been found that neurasthenics and patients with gastroenteroptosis do better when the adipose tissue has been restored or brought above normal, and the hyper-alimentation treatment has the two-fold purpose of relieving the neurasthenic state and replacing the intra-abdominal pressure by the deposition of fat in the omentum. In connection with the rest-and-fattening cure it is advisable to elevate the foot of the bed or to place a pillow beneath the buttocks in order to favor the upward return of the viscera by gravitation. With the same object in view it is well, also, to have the patient assume the knee-chest position for brief periods several times a day.

Since the abdominal muscles play so important a part in the maintenance of the intra-abdominal pressure by which the abdominal organs are retained in position, and since these muscles are always flabby in the "habitus enteroptoticus," it is necessary to employ measures to restore their tone. One of the best means for the accomplishment of this end is systematic abdominal gymnastics, and patients should be instructed in these procedures and required to practice them religiously.

The gastroenteroptotic patient is often a neurasthenic and usually mentally depressed, and in order to obtain the best results he should be placed in cheerful surroundings, with normal cheerful companionship and mental and physical relaxation. Association with other invalids should be avoided, and the patient encouraged to indulge in mild out-door sports. New interests, new surroundings, perhaps new friends, when combined with proper rest, food, hygiene and exercise will go far to stabilize the nervous system, promote appetite and restore the normal muscle tone, and when these goals have been achieved the patient will be well on the road to recovery from the distressing subjective symptoms, if not from the pathological displacements, of gastroenteroptosis.

THE AMOEBA AS THE CAUSE OF THE SECOND GREAT TYPE OF CHRONIC ARTHRITIS

Preliminary Note

By LEONARD W. ELY, M. D.,
Associate Professor of Surgery, San Francisco,

ALFRED C. REED, M. D.,
Assistant Clinical Professor of Medicine, San Francisco,

And

HARRY A. WYCKOFF, M. D.,
Clinical Pathologist,
Stanford University Medical School, San Francisco.

By the second great type of arthritis we mean that form of arthritis hitherto described by the Germans as arthritis deformans, by the English as osteoarthritis, by Goldthwait as hypertrophic arthritis, by Nichols and Richardson as degenerative arthritis, and by other writers under various titles. This is the senile form of arthritis, the chronic rheumatism of the elderly. For want of a better name some writers have called it metabolic arthritis, a singularly unfortunate and quite meaningless term.

In previous papers[1] Ely has set forth the pathology at length, emphasizing the fact that the primary change is a necrosis in the bone marrow in the region of the joint, and that all subsequent changes in the bone and in the cartilage are the result of this necrosis. All efforts to find the cause of the necrosis have been in vain. Everything in the bone indicated that the changes are caused by some form of organism, which killed by shutting off the blood supply, but all attempts to find the organism have been fruitless. We had been searching for a bacterium, in spite of the fact that the pathological anatomy of this disease, both gross and histologic, was absolutely different from that of the arthritides caused by bacteria, e. g., the tubercle bacillus, the treponema pallidum, the diplostreptococcus, etc. Ely has repeatedly called attention to the presence of infection about the roots of the teeth in patients with this type of arthritis.

Some months ago the conception of the relationship of amœba to this problem was suggested by Doctor J. V. Barrow, of Los Angeles, who had been working with Professor C. A. Kofoid, and who had found the amœba histolytica (sive dysenteriæ) in the stools of one of Ely's patients. Since then we have pursued this line of investigation in the Stanford Medical School and are conducting the work as a joint research. A full report of our investigations will be published at a later date. Doctor J. A. Campbell of the Dental Department of the Stanford Clinic has rendered valued assistance.

Paraffin sections of the bone in the region of necrotic areas from this type of arthritis were cut 4 to 8 microns thick. Stained by the standard iron hæmatoxylin method, the sections showed organisms identified as endamœba histolytica. These organisms were abundant in the region of necrotic areas in the marrow, but not actually in the necrotic areas. They were especially abundant in the immediate vicinity of the capillaries. Photomicrographs will appear in a later communication. We appreciate that we are but on the threshold of the problem, and this progress note is published to stimulate criticism and promote further research. It is only proper to state that our findings lack unanimous confirmation.

We ask for material removed at operation upon patients with this type of arthritis. It should be placed immediately in Schaudinn's solution at a temperature of 50° C., and may be mailed to us in a sealed container.

[1] Ely, Leonard W. The Great Second Type of Chronic Arthritis—Further Studies. California State J. of Med., 1921, v. XIX, 415.

ON THE OCCURRENCE OF ENDAMOEBA DYSENTERIAE IN BONE LESIONS IN ARTHRITIS DEFORMANS

By CHARLES A. KOFOID, Ph. D., Sc. D.,

And

OLIVE SWEZY, Ph. D.

Contribution from the Zoological Laboratory, University of California, and the Division of Parasitology, Bureau of Communicable Diseases, California State Board of Health, Berkeley, California.

A portion of the head of a human femur removed by operation in a case of arthritis deformans, fixed in formalin, decalcified and sectioned by Dr. Leonard W. Ely and stained in iron hæmatoxylin and examined in the zoological laboratory at the University of California, reveals a pure infection of amœbæ about the characteristic lesions in the bone. No stained bacteria have been found in our examination. The amœbæ are somewhat localized about the centers of necrosis near the articular surface. They are more abundant around the capillaries in the peripheral zone around the lesions. The organisms interpreted by us as amœbæ are unlike known normal or pathological tissue cells. They have the characteristic nuclear structure or *Endamœba hysenteriæ* Councilman and Lafleur, found in tissues about amœbic ulcers in intestinal amœbiasis. Their nuclei are unlike those of *Endamœba gingivalis* found in gingival abscesses and in granulomas of extracted teeth. Their nuclei are unlike the characteristic nuclei of other known parasitic amœbæ of man, and unlike those of normal and pathological tissue cells as figured in standard treatises and found by us in available preparations of human bone and bone marrow. The stained amœbæ show many instances of characteristic amœboid pseudopodia. Their distribution is unlike that of any known tissue element.

In the interest of further investigation, it is desirable that stool examinations for amœbæ be made in cases of arthritis deformans. Stools for such examinations may be sent for three to six successive days in legal mailing cases only, or by prepaid express to the Division of Parasitology, State Hygienic Laboratory, Berkeley, California, for examination by the writers.

FALLACY OF THE USUAL TESTS FOR SWIMMING POOLS

By J. W. ROBINSON, M. D., Deputy Health Officer, Los Angeles County

Public health officials should realize their responsibilities in the proper sanitary control of swimming pools, because of their importance in the spread of communicable diseases, particularly in infections of the eye, ear, nose and throat. This is distinctly a medical and not an engineering problem. Engineers have done commendable work in building and supervising swimming pools, but without comprehensive knowledge of medicine, including bacteriology and sanitation, they have not appreciated the dangers of this form of infection. The tests usually applied to protect the public, while good, do not go far enough. Swimming pool infections of the eye, ear, nose and throat are not only dangerous, but difficult to prevent. Mucous or pus containing hemolytic streptococci, pneumococci or other infective organisms are separated from the swimmer by direct washing, coughing, sneezing, blowing the nose or expectorating, and floats upon the surface of the water. It is then easy for some of this infective material to get into the eye, ear, nose or throat of other bathers.

The usual methods of testing water fail to show this danger and lead to false security. I am convinced that many of the "colds caught" by the people while in the swimming pool are actually swimming pool infections. The literature contains many somewhat casual references to the dangers of swimming pools. Harrington & Richardson's "Practical Hygiene" merely mentions it. McNutt, in "Manual for Health Officers," says: "Swimming pools have been suspected of transmitting eye affections, typhoid and other diseases." Rosenau, in "Preventive Medicine and Hygiene," states that "The diseases contracted in swimming pools are inflammatory infection of the upper respiratory tract and conjunctiva and injury and inflammation of the ears."

In an excellent article by Simons (American Journal of Public Health, March, 1921), regulations prohibiting expectorating are provided, but the subject of infection is casually treated. The outlet for water mentioned in this article is not in a proper place, as I shall show later.

In their rules for sanitation and safety of swimming pools, adopted December 4, 1920 ("Special Bulletin No. 38"), the California State Board of Health have, to a considerable extent, recognized these dangers and have taken steps to correct them, but not nearly as fully as is desirable. Rule 3 states: "Facilities for adequately protecting the pool waters against unnecessary sputum contamination by bathers must be provided. In order to keep the surface of a swimming pool reasonably free from sputum and objectionable miscellaneous floating contamination, it is necessary to provide both convenient and proper places for expectoration by bathers, and means for frequently or continuously skimming off the surface water. The device used in practically all up-to-date swimming pools to meet this requirement is the combined overflow and expectoration gutter, extending completely around the pool." In Rule 2, they mention the desirability of having the water flow into and out of the pool at various levels. Rule 4 states: "All persons known to be or suspected of being afflicted with infectious diseases shall be excluded from the pool." This is very good, but who is going to determine whether or not bathers are infected? When they enter pools in large numbers, in a short time even a trained observer could not possibly locate cases of a communicable nature. So, for safety sake and practical results, one must consider that a certain percentage of all people who enter a swimming pool are carrying communicable infections, and adequate provisions must be made to protect the other bathers.

As in many other conditions, it is easier to point out an evil than to correct it. A practical solution can only result from intelligent discussion by a number of people looking at it from different angles. The California State Board of Health rules are in the right direction, but they are not specific enough. As a practicable contribution to this subject, I would suggest:

First—In order to prevent stagnation of waters in corners, except what is overcome by the movement of bathers, the location of supply and drainage pipes should be specifically stated by Boards of Health or of Engineering.

Second—In addition to rules concerning clearness and bacterial counts, there should be a rule stating the frequency with which water should be changed, on a basis of a certain number of cubic feet to each bather, or in ratio of the surface area per bather. There should be a constant flow of water from the surface into the overflow gutters, and this water should be supplied by as many intake pipes and removed by as many overflow pipes as is necessary to keep all parts of the surface of the water changed. To accomplish this satisfactorily, the flow of water should be across, and not lengthwise of the pool, in order that mucous floating on the surface would be there the minimum amount of time.

Third—Methods should be worked out of skimming the surface of the water to examine for pus or other infectuous material.

Fourth—A law should be enacted making it a misdemeanor for an infected person to enter a swimming pool.

Adrenalin—Up to 1900 the medical profession had to be content with extracts and other preparations of the suprarenal gland that contained, besides what was wanted, a good deal of inert and possibly irritating material.

One manufacturing house, at least, was engaged in making a discovery—the isolation of the active principle of the suprarenal gland, or, if it is not quite accurate to speak of it as "the active principle," the pressor or blood-pressure-raising principle of the gland. For it was known that such a principle was contained somewhere in the gland substance, from the observed effect of aqueous solutions of suprarenal extracts; and it was this principle in pure form that was wanted.

Adrenalin, the pressor principle sought, has been in use by the profession since 1901. The manufacturers of adrenalin carry an advertisement in this Journal.

A PROBLEM IN MEDICAL ECONOMICS

Modern business co-ordinates the facilities and resources necessary to produce a given result. This requires the harmonious blending and utilization of specialists in direct and collateral lines—organization. Similar policies prevail in some of the professions. It is not usual to see a successful attorney constituting a unit of service. Why? Simply because it is better business for the lawyer and better business for clients for several men, specialists in the various branches of the law, to associate themselves together. Progress along almost all lines, with improvement in service to the public and in net income to the workers, is the result of combinations of efforts into efficiency units of greater scope than may be found in one man.

To a large extent physicians are still trying to handle the great humanitarian service of the prevention and cure of disease on the basis of competition between individuals when, as a matter of fact, the discharge of our full duty requires a larger unit. No one man can be a competent unit for the discharge of all the duties of the physician. Not having the group organization of the business world and other professions, there is a strong tendency to act as brokers for the things we cannot do adequately.

The vices of *secret* fee-splitting, expensive institutions and many other familiar problems are perfectly natural outgrowths not of our faulty science, but of our faulty business methods. The one-man unit of service in medicine in this modern day sometimes means mediocre service to the patient, or brokerage connections that are expensive to the patient and time consuming for the physician. These basic facts explain to a large degree why our field of activity is being constantly narrowed, our work beyond individual effort made less effective, and the average income of physicians kept at a disgracefully low figure.

Governments and municipalities and non-medical voluntary societies have taken over most of the great field of preventive medicine; practically all large corporations have their own medical departments, run on business bases; insurance companies maintain medical departments and build and operate their own institutions; accidents and injuries are handled largely by the State, and so on through a long list, showing a constantly narrowing field for the individual independent medical man, while the big work of our profession in the prevention and cure of disease and the institutions necessary to our work are passing out from medical control to lay business management, and physicians are becoming more and more employes of the organizers of system or of politics.

It behooves the medical profession to give these matters more serious attention than they are now giving and to take the lead in solving what should be their own problems.

It is possible and desirable that competent physicians associate themselves together in groups in such a way that they can render better service, more economically, to sick people than they are now doing as individuals. This can be done and is being done by certain groups in such a way that there is no undue or unfair competition with the individual physician and in such a way as not to endanger the personal responsibilities and relations between the patient and any member of the group.

The first essential in any group formation is, that it have as executive a non-practicing member who has a practical economic training and at the same time has the true physician's ideals, altruism and love of service.

WILL "FOOD SPECIALISTS" SUPERSEDE PHYSICIANS

Before answering more definitely the inquiries that are being received from physicians over the State regarding nutrition and dietotherapy publicity, and in order that opinions of physicians may be available, the editor welcomes answers to the following questions:

Is nutrition and dietetics a medical or a non-medical subject?

Is dietetics, as it is being used in popular parlance, developing into another novel "system" of medicine? Why all the books and other publications by M. D.'s and other D.'s discussing the new (?) "science" of nutrition? Why the extensive independent organizations? Why the constantly expanding and extending courses by some schools? Why so much propaganda in so many private commercial, scientific, hospital, nursing and similar magazines? Why is it that most of these articles are thinly disguised criticisms of physicians and hospitals? Who is paying for the propaganda invading the movies, the fairies, the expenses of traveling lecturers and other circus food performers?

What is the meaning of the reports now coming into every medical center of the diabetics, chronic nephritics and other patients who are under the care of "food specialists" and food purveyors? Why do newspapers find it profitable to have "food specialists" pages? Why do department stores run dietetic departments? Why are so many mixtures of bran and chaff being advertised?

Is the public being prepared for the announcement of a new specialty of medicine to be conducted by non-medical persons? Has the time arrived when many persons are now being treated by these people without reference to a physician? Is it not about time that physicians gave this question some serious attention?

MINERAL WATERS

Among other classes of advertising, the California State Journal of Medicine carries the advertisements of a number of wholesome waters of one sort or another. Its columns are open to any ethical advertisement of an ethical product. The fact that an advertisement is carried in the Journal should be, and is, interpreted by every member of

the State Medical Society as an official endorsement.

There are a large number of so-called mineral waters on the market that are not advertised in the Journal and could not buy space in it at any price. The office has recently been furnished literature showing the endorsement by some of our members of waters that belong in this category. In some instances that have been investigated, it was found that the physician did not give such endorsement and did not authorize the use of his name; in others, physicians, without thinking seriously of the matter, have alowed their names to be used.

This matter is one of more importance in consideration of the public welfare and public health than is generally realized, and it is requested that before members of our society endorse a mineral water or other advertised products, they communicate with their State Society and find out the standing of the substance in the eyes of the medical profession.

THE ART OF MEDICINE

Abstracts from a Sympposium on this subject appearing in the New York Medical Times, August, 1921.

"Those of us who, now growing old, were brought up under great artists in healing, are more and more putting to ourselves the query: 'What is to become of the loftier motives and methods of remediation when the Art of Healing comes to merge into the strict Science of Medicine; when there shall come to be swept away such cobwebs, rather gossamer somethings, which once glorified the clinical domain?' Maybe they ought to fade away among fairy tales, fables, folk lore, epic poems, the spirit of chivalry, and other gracious influences, but there are those of us who cling fondly to the old order and feel a great regret that to perhaps most of our younger men it means nothing, for there was something in it without which their spiritual ductless glands, so to speak, will not functionate perfectly—indeed, without which their boasted science will be as sounding brass and tinkling cymbals.

"'Oh! the little more and how much it is;
The little less and what worlds away!'

"It is a deplorable thing that the fusion of what was best in the old regime with the new order of things could not have been more complete. Our highly evolved technology has made science a fetish, to the exclusion of all things else. And the Lenins of science have made the humanists afraid to call their souls their own. Hordes of these tyrants live by the laboratory, and, like a lot of ancient priests ruling a tribal people, sally forth from their temple now and anon to intimidate us with their incantations, which never fail to compel genuflections from a profession more superstitious than the rabble of the Middle Ages; we are science-ridden as men were once priest-ridden. So complete has been the change that there are doubtless standardized younger men who may read this editorial without sensing just what it is all about, or who have been so materialized as not to care. It is largely in the hope, however, that some of these Sauls will see a light as they journey toward a futile Damascus that we have written these things." (Editorial which appeared in May issue of the Medical Times, which occasioned the responses which make up the Symposium.)

"To do a thing so well as not only to surpass one's expectation of one's self, but deserve the commendation of one's fellows, comes near to being a definition or art." (J. Madison Taylor, M. D.)

"The secret of success in medicine lies in the close personal interest in patients, and one's personal power to influence them morally, spiritually and mentally—and *through these physically*. That contact is being lost by the diversity of processes which people are now put—laboratories, X-rays, chemists, dentists, etc.—all of which detract from the personal element. Hence, as an art, medicine is losing." (M. Allen Starr, M. D.)

"In the last analysis, the strength of an organization will be found to rest on the character and equipment of the individual members. One would gather from many of the various 'social welfare' undertakings prevalent in this day that the study of man as man had been abandoned, that the springs of human action had been forgotten, and that a new being was in process of creation. Marx's system of socialism, with which many have been so enamored and which has tainted multitudes and disturbed the body politic, lost sight entirely of the nature of the being it was attempting to deal with for this very reason. This system, as many collateral ones, failed to take note that besides appetites, man, as he came from the Creator's hand, possesses affections and mental desires and moral sentiments and also those reflex sentiments, as exhibited in the desire for love and esteem and self-approval. That failure dooms all such systems to destruction from their beginning. It is only in allowing and encouraging man to apply his personal ability and to make the best of it that progress is made. This is illustrated in every department of human endeavor." (Henry A. Fairbairn, M. D.)

"I have not yet spoken of medicine as an art—as a fine art. It is, in my belief, or should be, the finest of them all. The doctor, the beloved physician, should care for men's bodies the best he knows how, until recovery or the end comes. When the latter, alas, he should bow his head, bend his knees and call in humble prayer to the Almighty Saviour of all men to have mercy upon the man or woman who has gone, and upon all who are left behind and who are near and dear ones, still on earth. Can pure science ever give us such a vision, or come near to such a calling? I do not believe it. I stand for everything that is true and good in the science of medicine, but I proclaim most earnestly that what, after all, has to do with man's most sacred and endless emotions, aspirations, beliefs, affections, and with love over and beyond everything, must ever be and remain the noblest, the best of all human arts." (Beverly Robinson, M. D.)

Yosemite's Comfortable Cabins

To the average person, the term "cabin resort" conjures up some dreadful vision of sleeping on the ground and eating from a tin plate. Let it be said here for the benefit of those who will attend the 1922 convention of the Medical Society of the State of California in Yosemite National Park, May 15 to 18, that the trip involves no such hardship or sacrifice of comfort.

"Why it isn't like the mountains at all," exclaimed one woman from the East, a guest at Yosemite Lodge, when she learned that she could have her breakfast, piping-hot, served at her bedside any morning that she desired to give the order.

Such a comment was not intended to mean that the noble cliffs and waterfalls of Yosemite Valley had been ruined by the erection of buildings out of keeping with the natural surroundings; rather, it was a spontaneous compliment to service rendered at the Lodge, fifteen miles from a railroad, service that measured up to standards of city hotels and far exceeded what the visitor had found at mountain resorts in other sections.

Yosemite Lodge is a little city in itself. "A charming colony of redwood cabins under the pines at the foot of Yosemite Falls, the cabins being grouped around a community center of office, dining-room, lounge, writing room, dance pavilian, theater, swimming pool, children's playground, and nightly camp fire" is the description usually given of it.

The Lodge has its own postoffice, the name of which is Yosemite Lodge, Calif., and mail so addressed is delivered direct from trains without the delay of going through the main office in the village, the name of which is Yosemite, California. The Lodge also has its own telegraph station, Yosemite Lodge, Calif., and long distance telephone facilities. Baggage can be checked straight through to Yosemite Lodge.

In the American Plan dining-room of the Lodge, there is individual service for each guest. The dining-room linen is snowy white, and waitresses and bus boys are uniformed in white.

The other public rooms and broad verandas of the Lodge main group need no special mention, but a word should be said here about the services in the swimming pool group, just across the plaza. The pool is 120 feet long, filled with crystal mountain water, which is heated to a comfortable temperature by steam. Suits can be rented. After a plunge, there is a barber ready to serve the men, a beauty parlor with all modern equipment for hairdressing, facial treatment and manicuring for the women. The laundry in the same group offers high-class service, including the cleaning and pressing of clothing.

Every evening there is an entertainment of merit at the Lodge free to all guests. It might be mentioned here that Ruth St. Denis and Ted Shawn, internationally famous dancers, were among the artists who appeared at the Lodge last year. Every evening except Sunday there is dancing to the music of an excellent orchestra.

A word also should be said about the "cabins" which make up the Lodge's living quarters. Three types of cabins are provided.

The first type is built of redwood in rustic style that harmonizes with the tall pines and spruces around. A generous porch gives entrance to a bedroom with twin beds and other furniture of special design and finish. Dressing room, closet or wardrobe provides ample space for hanging up clothes. The bathroom includes tub, washbasin and sanitary flush toilet of spotless porcelain; in a few of the cabins there are shower baths. Many of these cabins also have screened and curtained sleeping porches on the rear. Electric stoves, 5000 Watts, furnish heat at a turn of the button. American plan, rate $7.50 per person per day.

Redwood cabins without bath make up the second group. Like the cabins with bath, they are furnished with twin beds. Sliding curtains are arranged so that each cabin, 12 x 14 feet in size, can be divided into two private sleeping compartments and a sitting room. Bowls and pitchers are provided and small stoves burning fragrant cedar or pine wood are used for heating. American plan, rate $5.50 per person per day.

Canvas cabins form the third group—and do not confuse the Lodge's canvas cabins with tents. Canvas cabins here are all that the name implies—houses with canvas for walls. They are floored, have electric lights, a screened door and six screened windows with awnings and curtains. Furnishings are similar to those in the redwood cabins without baths. European plan, rate (lodging only) $1.50 per person per day. American plan, rate (with meals in Lodge dining-room) $5.50 per person per day.

Maid service in all cabins assures plenty of towels and, in the cabins without bath, fresh water also. Hot water for the morning toilet may be had without extra charge by those living in cabins without baths, by leaving number of cabin and hour desired at the office of the Lodge.

COME TO YOSEMITE

MAY 15 TO 18

1922

Chaulmoogra Oil Therapy in Leprosy

EDITOR'S NOTE—Literature is rapidly accumulating regarding chaulmoogra oil and its use in the treatment of leprosy. Lay publications are taking an interest in the discussion of the subject and some of the literature, both in scientific journals and lay press, fails to give credit where credit is due. We have received a number of letters of inquiry from physicians regarding the inaccuracies that are being published. In reply, the Journal has had the following notes prepared covering the outstanding features of the oil and its therapeutic value. Comparatively few people realize the fact that much of the recent progress in this field is due to researches carried out in the Hooper Foundation for Medical Research in San Francisco.

Chaulmoogra oil is obtained from the seeds of a tree, Taraktogenos kurzii, native of Burma. This tree bears a fruit the size of an orange, containing many irregular, brown seeds, rich in oil. The oil, which is expressed cold from the seeds, is a heavy oil solidifying at 22°-23° C. and having a characteristic disagreeable odor.

The chemistry of chaulmoogra oil was first adequately investigated by Power and his collaborators at the Wellcome Chemical Research Laboratories, London, from 1904 to 1907. Their investigations disclosed that chaulmoogra oil consists chiefly of the glycerole esters of a hitherto unknown series of fatty acids, having peculiar structural and chemical properties. All previously known fatty acids have a straight chain arrangement of the atoms in the molecules and are optically inactive; acids of the chaulmoogric series have the atoms arranged in a five-membered ring with a side chain of variable length and are optically active. These authors isolated and determined the constitution of two fatty acids of the chaulmoogric series: chaulmoogric acid, $C_{18}H_{32}O_2$ and hydnocarpic acid, $C_{16}H_{28}O_2$. It is probable that one or more lower homologues of this series are also present in chaulmoogra oil. Subsequent investigations have shown that these cyclic fatty acids are present in variable quantities in the seeds of many trees closely related to Taraktogenos kurzii, belonging to the botanical family Flacourticeae, but not elsewhere.

Chaulmoogra oil has had a popular medicinal reputation among the natives of India since prehistoric times, being employed externally and internally for the treatment of leprosy and also for the treatment of various skin diseases for which it is probably useless.

The first use of chaulmoogra oil by the medical profession in the treatment of leprosy is somewhat obscure. Morrow states that the drug was first used by Le Page of Calcutta. British scientists, it is stated, undertook the distribution of the seeds of Taraktogenos kurzii in 1856, but by mistake collected the seeds of an entirely different tree. By the end of the nineteenth century, it had become generally recognized that chaulmoogra oil was the only drug that offered any prospects of a successful treatment of leprosy; but many leprologists considered it rather as a palliative than a curative agent. It was formerly administered in the form of a crude oil, by mouth. This oil is, however, so nauseating and causes such serious digestive disturbances that few patients are able to continue the treatment long enough and intensively enough to obtain therapeutic results. Nevertheless, the literature records a considerable number of cases of leprosy improved, arrested and even apparently cured by this method of administration.

Many attempts have been made to obviate the digestive disturbances and to otherwise improve the therapeutic action of the oil. Subcutaneous and intramuscular injections were tried as long ago as 1899 by Tourtoulis-Bey, in Cairo, with some beneficial results, but no cures. The heavy oil is slowly absorbed, causes much pain and sometimes abscesses and occasionally pulmonary embolism. Somewhat better results have been obtained by the subcutaneous or intramuscular injection of various mixtures of chaulmoogra oil, of which the essential feature is the thinning out of the heavy chaulmoogra oil by a lighter oil, in order to obtain better absorption. The best known of these mixtures is that of Heiser and Mercado, which has been used quite extensively. Heiser reported a number of apparent cures of leprosy by its use in the Philippine Islands.

A second method of overcoming the drawbacks to the use of crude chaulmoogra oil has been to separate the fatty acids and convert them into the soluble sodium salts. There were some earlier attempts to make use of the fatty acids and their salts in leprosy, but, however, the first serious employment of this method in the treatment of leprosy was by Sir Leonard Rogers in India in 1916. Since that time the sodium salts of chaulmoogric acids have been employed by Rogers and his collaborators very extensively, both by subcutaneous and by intravenous injection, in the treatment of leprosy in India, with a reported high percentage of improvement and many apparent cures. The sodium salts have the disadvantage, however, of being very irritating to the tissues.

Rogers is of the opinion that the therapeutic action of chaulmoogra oil in leprosy is due, not to the peculiar cyclic structure of the chaulmoogric acids, but that it is a property of unsaturated fatty acids in general, which attack in some manner the acid-fast bacilli. He has, therefore, prepared the sodium salts of the fatty acids of cod liver oil, which he calls sodium morrhuate, and later of the fatty acids of soya bean oil. Rogers and his collaborators have used these preparations in the treatment of leprosy, and claim equally as good therapeutic results as with the sodium salts of chaulmoogra oil. Rogers also suggested that the unsaturated fatty acids and their salts might be of therapeutic value in tuberculosis, and he and his colleagues have employed sodium morrhuate for this purpose and reported some encouraging results.

Power and Gornall (1904), during their investigation of chaulmoogra oil, prepared the methyl and ethyl esters of chaulmoogric acid and studied their properties. In 1909, Ludwig Taube obtained a German patent, assigned to Farbenfabriken vorm. Friedr. Bayer & Company, of Elbereld, Germany, and later patents in England and the United States, covering the preparation and use of the ethyl esters of chaulmoogric acids in the treatment of leprosy. This derivative of chaulmoogra oil was put on the market under the trade name of "Antileprol." Antileprol appears to have been used by a few physicians with indifferent results, and to have attracted but little attention of leprologists. Subsequent to the war and the confiscation of German patent rights, the Alien Property Custodian of the United States Government sold the patent rights for the preparation of the ethyl esters of chaulmoogric acids ("Antileprol") to the Winthrop Chemical Company, of New York, who have put this derivative on the market under the trade name of "Chaulmestrol."

In 1919, Hollman and Dean sought a non-irritating and readily absorbable derivative of chaulmoogra oil for treatment of lepers in the Hawaiian Islands. Dean, President and head of the Department of Chemistry of the College of Hawaii, prepared the ethyl esters of various fractions and of the total fatty acids of chaulmoogra oil, which Hollmann used for the intensive treatment of lepers. This therapeutic investigation was later continued by Dean and McDonald. In their latest publication (1921), McDonald reported 142 cases of leprosy paroled as apparently cured by intramuscular injections of the ethyl esters of chaulmoogric acids during the preceding two and one-half years.

At present, Professor Dean and his assistant, Dr. Wrenshall are working on esters of lower homologues of chaulmoogric acids which have a lower molecular weight, are more highly unsaturated and are believed to have a greater therapeutic value. Meanwhile, the clinical side of the work has been taken over by Dr. Hasseltine, of the United States Public Health Service. The United States Public Health Service has taken a conservative stand on the therapeutic results of the ethyl chaulmoograte treatment of leprosy in the Hawaiian Islands, as is indicated by a short article in Public Health Reports (1921). Some relapses of paroled patients have occurred, and they prefer to speak of the paroled patients as having the disease arrested rather than cured. The report states: "In properly selected cases, especially in the young and in those who are in the early stages of the disease, the clinical improvement is rapid and striking. The result is less favorable in older persons and in case of long duration. At this time, we cannot say that the ethyl esters of chaulmoogra oil are a cure for leprosy."

Until 1920, the use of chaulmoogra oil and its derivatives in the treatment of leprosy was wholly empirical. There existed no scientific knowledge of how chaulmoogra oil acted in leprosy, the nature of the active substance in the oil, and whether its therapeutic action was specific for leprosy or might include other diseases. In that year, Walker and Sweeney, working in the George Williams Hooper Foundation for Medical Research, San Francisco, published the results of an investigation of these problems. It was determined experimentally that chaulmoogra oil contains substances having a high bactericidal activity. This bactericidal activity was found to reside in the fatty acids of the chaulmoogric series, and to be a function of the carbon ring structure, which is peculiar to the chaulmoogric acid series. The bactericidal activity of these cyclic fatty acids was shown to be specific against the acid-fast group of bacteria, to which the bacilli of leprosy and tuberculosis belong and absent toward all other bacteria. Walker demonstrated that other unsaturated fatty acids, such as those of cod liver oil, did not possess the specific bactericidal activity of the chaulmoogric acids. From these experimentally determined facts, it was concluded that the therapeutic action of chaulmoogra oil and its derivatives in leprosy was due to its direct bactericidal action; that Rogers' claim for the therapeutic action of the sodium morrhuate was unsupported; and it was suggested that there were theoretical grounds for believing that chaulmoogra derivatives might be of therapeutic value in tuberculosis.

NATIONAL BOARD OF MEDICAL EXAMINERS

This board was organized in 1915 as the result of action by the American Medical Association. Its purpose is to establish in the United States a standard qualifying examination which can be safely accepted by all State Boards of Medical Licensure as an adequate qualification for the practice of the healing art. Although in operation only six years, this board is now accepted by the United States Army, Navy and Public Health Services as qualifying for admission to their medical departments. The boards of medical examiners of twenty States now also accept the reports of this board in lieu of their own examinations.

The importance of this board is being more and more realized and the magnitude of its work is increasing tremendously. The method of examination has been modified so that it may be taken in three parts at separate times. Persons who desire to take this examination and who are interested in its workings—and this should include every young physician in the United States—should address Dr. J. S. Rodman, Secretary, 1310 Medical Arts Building, Philadelphia, Pa.

Lane Lectures

Summary of Lane Medical Lectures for 1921 delivered by Dr. L. Emmett Holt, Emeritus Professor of Pediatrics, College of Physicians and Surgeons, Columbia University, New York, at Stanford University Medical School. (Reported by H. K. Faber, M. D., Stanford University Medical School.)

The eighteenth course of Lane Medical Lectures was delivered by Dr. L. Emmet Holt, Emeritus Professor of Pediatrics, College of Physicians and Surgeons, Columbia University, New York, on the evenings of December 5, 6, 7, 8 and 9, 1921, at Lane Hall, Stanford University Medical School, San Francisco, California.

The first lecture reviewed the problems of nutrition, especially as they affect children, the main emphasis being placed on the period after the second year. While underfeeding in adults impairs efficiency it may not greatly impair health, but in children it prevents growth, both mental and physical, and impairs health as well. Resistance to disease is lessened and children become underweight, stunted and anemic.

The selective draft showed about 30 per cent of our young adults unfit physically for military service, and statistics of our schools show that about the same proportion of our school children are underweight or suffering from the effects of malnutrition. The responsibility for this lies with the home, the State and the medical profession. Parents are ignorant of the simplest principles of nutrition; discipline is largely wanting and poverty plays also a certain part, though less in importance. Our medical schools lay too much emphasis on disease and too little on health. The physician's office is too much regarded as a repair shop. The Federal, State and municipal governments have largely neglected the health of children. $9,700,576 was appropriated for the Department of Animal Industry against $271,000 for the Children's Bureau. The average appropriation in twenty-four cities with a population of 250,000 was $1.05 per capita and in eighty cities with a population over 12,000, 71 cents per capita. Many good-sized towns spend less than 15 cents per capita, less than the average admission to a moving picture show.

Stature is affected more by food than by climate. Japanese children in this country are taller and heavier than those in Japan. Native American children of the present generation are taller and heavier than their parents. Nutrition has an important bearing on progress in schools. Ayers has shown a close correlation between the nutrition and the proficiency in their studies of school children in Deroit. Moreover, poor nutrition makes children enter school late and have frequent absences. We cannot fill the head when the stomach is empty, nor can we expect application or concentration of mind from an anemic, nervous child who is twenty or thirty pounds below normal weight. The estimated cost of educating retarded children in the United States is $27,000,000 yearly. It might prove a matter of economy, if some part of this $27,000,000 was devoted to health education and hot school lunches.

The state of nutrition has a very important bearing on resistance to disease. Trudeau's experiments with tuberculosis in guinea pigs shows this, and clinical experience with pneumonia, empyema, typhoid fever, dysentery and other infections point to the same conclusion. The number of specific remedies for disease is small, and for a long time to come it will be the duty of the physician to treat the patient rather than the disease itself. This means very largely the maintenance of nutrition. Growth and repair are closely related processes and influenced by much the same conditions. This is particularly true in childhood. If underfeeding is continued past the normal period of growth, later growth becomes impossible

and dwarfing occurs. This has been shown experimentally and clinically. If to prolonged underfeeding chronic disease is added, which is so often the result of such feeding, the consequences are likely to be permanent stunting of growth, a high mortality in early adult life, impaired physical energy, lowered mental capacity and premature old age.

Through education infant mortality has been enormously reduced. It is not too much to expect that with a better understanding of the subject of nutrition there may be accomplished for the older child something comparable to what has been done for the infant.

SECOND LECTURE

The subject of this lecture was the metabolism of childhood. The requirements for basal metabolism are fairly uniform for children of the same age and weight. Requirements for growth are naturally greatest during the periods of most rapid growth. There are two such periods: first, during the first year, and second, with the approach of puberty. The maximum demands for growth are for girls during the thirteenth year and for boys during the sixteenth year, after which the requirements decline to nothing at the end of the growth period. Eight to fourteen per cent of the entire food taken is required during childhood. The loss in the excreta at all ages is about 10 per cent of the food given. The requirement for activity varies enormously with different children. With some it is two to three times as great as with others. The activity requirement is made up of two factors, first the energy consumed in the processes of the digestion, which is about 6 per cent of the food taken, and second, the amount needed for muscular activity. The latter begins to increase rapidly when the child learns to walk and increases steadily but not rapidly from then on to the time of puberty. The great differences in activity are not sufficiently taken into account in providing diets for children. A very active child may use up so much food for energy that he has none left to supply the needs for growth. Especially during adolescence the food requirements given in the earlier estimates have been much too low. At St. Paul's School in Concord, N. H., it was found that boys between thirteen and seventeen years of age took an average of 5000 calories daily. Compare this with the usual allowance of 3400 calories for an adult man doing moderate work, and the allowance of 3800 calories for soldiers in our army camps. The enormous appetite of boys and girls during the rapidly growing period has a sound physiological basis. If these food needs are not satisfied, both growth and physical development suffer.

An interesting analogy was drawn by the lecturer between food intake and the use of monetary income. Overhead expenses correspond with the basal metabolic needs, normal activity, loss in excreta and digestive work. The remainder may be spent (used in excessive activity) or saved; that is, used for growth. Excessive activity is always at the expense of growth, unless the amount of food taken is correspondingly increased.

THIRD LECTURE

In the third lecture the special uses of protein, fat and carbohydrate were discussed. The protein must be adequate both in amount and in quality to assure proper growth. Many protein foods, especially the vegetables, do not contain adequate amounts of certain essential amino acids. The protein of woman's milk contains all the amino acids required by infants in the correct proportions so that the 1¼ per cent of protein found in woman's milk is adequate. Animal proteins in general are high grade proteins, but are deficient in some respects. Thus cow's milk, which is relatively lacking in cystin and lysin, must be given in double or treble the quantity required with woman's milk to insure adequate growth. The best results in children are obtained when 15 per cent of the food is protein with fully two-thirds of it as animal protein. Fat, in spite of occasional assertions to the contrary, is an essential part of the diet. Certain diseases, especially kerato-malacia, comparable to the xerophthalmia found in experimental animals, are occasionally seen when children are fed on a fat-free diet. Fat is the carrier of vitamin A, which is essential in growth. Animals, but not children, can be reared successfully when low fat diets are given over long periods of time. Growth is retarded and susceptibility to infection increased. Normal stools are never seen in children fed on a low fat diet. The probable reason for this is that the soaps have the function of neutralizing the acid formed in the intestines from fermentation of the carbohydrate. The high fat content of all milks is a conclusive argument for the importance of fats in the diet of the young.

The carbohydrates have the advantage that they are cheap and usually well digested. In infancy most of the carbohydrate is in the form of sugar and after infancy about half is sugar and half starch. Charts were shown giving the proportion of fat, carbohydrate and protein, the distribution of carbohydrate as sugars and starch and of the protein as animal and vegetable proteins in the diet of 106 children studied by the lecturer. The proportion of 15 per cent of the calories as protein, 35 per cent as fat and 50 per cent as carbohydrate was strikingly constant. The optimum proportion of protein, fat and carbohydrate by quantity appears to be 1⅓. The sugar, which represented about half the total carbohydrate was distributed about equally between fruit sugars and cane sugar. About two-thirds of the protein was animal and one-third vegetable. The protein intake is about four grams per kilo at one year, after which it diminishes to 2.6 grams per kilo at six years, continuing at this figure until the end of the growth period.

FOURTH LECTURE

The vitamins were discussed. The danger of losing perspective because of the dramatic experimental effects observed and because of the wide publicity which these substances have obtained was emphasized. There are three recognized vitamins—the fat soluble, or vitamin A; the water soluble, or vitamin B, and the antiscorbutic, or vitamin C. These are indispensable for health and growth, and since the animal body cannot manufacture them they must be supplied in the food.

Vitamin A is present in animal fats, egg yolk, in liver and kidney tissues, and is particularly abundant in codliver oil. Vegetable oils contain practically none. It is also present in green vegetables such as cabbage, spinach and lettuce, and also in alfalfa and clover. The exact role of vitamin A in human nutrition, we do not know. Animals deprived of it cease to grow after a few weeks and suffer from sore eyes, which, if not treated, may be completely destroyed. A prompt cure occurs if a very small amount of butter or codliver oil is added to the diet. Similar symptoms have been observed in children occasionally.

Vitamin B is found in nearly all our foods in varying amounts. It is abundant in eggs, meats, seeds, vegetables, fruits, milk and in brewer's yeast. It is not injured in cooking or drying, but is removed from wheat in the process of milling, so that it is practically absent from white wheat flour. In animals, deprivation of this vitamin leads to muscular weakness and paralysis.

In man it leads to beri-beri.

Vitamin C, the antiscorbutic, is found chiefly in fruits and vegetables. Citrus fruits, cabbage and tomato are rich sources. It is nearly always injured and may be destroyed during the preparation and preservation of foods, though the sus-

ceptibility to heat varies. Dried cabbage, dried tomato and canned tomatoes are efficient antiscorbutics as also is dried orange juice or lemon juice, even when kept for a long period in sealed packages. In milk this vitamin is present in very small amounts, so that two quarts of milk contain only as much as one ounce of orange juice. Pasteurizing, sterilizing, boiling, drying or condensing injures this vitamin in milk to a greater or less degree so that the only safe rule is, when milk that has been heated in any one of these ways is used, to give some antiscorbutic such as fresh fruit juice or tomato juice. Half an ounce a day given regularly is sufficient to protect most infants. It appears that babies are born with a store of this vitamin sufficient to last five to eight months. It is important to remember that when enough vitamins are provided in the diet to avert the diseases caused by vitamin deficiencies this is all that can be accomplished by them. Giving greater amounts cannot accomplish further results. The use of vitamins without definite indications will be popular for a time like other fads. It is important to note that modern transportation conditions have made it necessary to refine and preserve foods (thus destroying much of the natural vitamin content) in order that large centers of population may be fed and may have reserve stores of food, hence the necessity for the use of a certain amount of fresh foods containing vitamins in our diet.

FIFTH LECTURE

The fifth lecture was devoted to a general consideration of how defects in nutrition can be met and overcome. Having considered the low standards of nutrition, which we have permitted to exist among children and other consequences in adult life, how can improvement be effected? The greatest agencies for promoting reform along any line are publicity and education. In child work we must combat not only the ignorance of the ignorant but, to quote Chesterton, the ignorance of the educated.

Malnutrition may be briefly defined as a condition in which a child has failed to reach the degree of physical development which may be considered normal for his age. The best simple standard is the weight and height, especially the weight for the height, which has been reached at any age, and the rate of increase in height and weight which is made each year.

Among the causes of failure to obtain normal physical development are bad inheritance, premature birth, previous acute or chronic illness, physical defects such as carious teeth, enlarged or diseased tonsils or adenoids. Failure in nutrition may be the first sign and only obvious symptoms of tuberculosis, nephritis, cardiac disease or grave anemia. The great majority of cases are due to improper food or faulty hygiene. Dietary defects are characterized by lack of essential elements of growth such as an adequate supply of high grade protein, a liberal amount of fat, an ample supply of mineral salts for bone and the three vitamins. All these are provided if reasonable quantities are given of milk, cereals, green vegetables and fruit, but they are not present in coffee, white bread or sweets. Bad habits, which adversely affect nutrition, are eating at irregular times, eating sweets and other trash between meals and rapidly eating without mastication.

Examples of faulty hygiene are overcrowding, lack of fresh air in sleeping rooms and school rooms, lack of opportunity for outdoor play, late hours with insufficient sleep, no opportunity for rest in the middle of the day after the third or fourth year, over activity with either too much work or too much play, so that no food is left for growth, habitually bad posture and chronic constipation from lack of regular habit.

As a criterion for under-nutrition the lecturer takes 10 per cent below the average weight for height under the age of twelve years with a somewhat larger allowable variation during the period of adolescence. Age must be taken into consideration since of two children of the same height the older is normally heavier. Two types of undernourished children may be distinguished; first, the dull, listless child who is easily fatigued and has poor muscular development and flabby tissues; second, the ambitious, excitable over-active child, hard to manage, who sleeps poorly and has good muscular development but little or no subcutaneous fat. Normal children occasionally fail to gain for a period of a few months, but a stationary weight, for a prolonged period or steady loss at any time, should never be disregarded. There are between six and ten millions of undernourished children in the United States in which four-fifths of whom the condition is remediable. The treatment is both preventive and remedial, the former being vastly the more important. Preventive treatment includes eugenics, suitable prenatal care, maternal nursing and the best infant feeding and hygiene. The child should receive better care than he does between the second year and the time he goes to school. He should be weighed at regular intervals and his diet and life should not be the same as those of the older members of the family. He should have a general physical examination by a physician every six months and the records thus obtained with those of his weight could be made available at the time of school entrance to the teacher and school physician. On school entrance every child should have a thorough physical examination in the presence of the parents by the school physician who would note any abnormalities and would then have a sound basis for planning school hours, work, exercise and athletics. While an examination of every school child at the beginning of each school year is desirable it is perhaps not feasible at present, but certainly a physical and mental examination should be required of every child whose school work falls much below the average. More can be accomplished by health education than by any other means. This must be directed to the children rather than to their parents, and it should be begun at an early age. It can be done better in the school than in the home. In school the child expects to be taught and what he learns has an authority which home teaching, with its don'ts and you mustn'ts, does not possess. The vital point is to make health attractive and its aim should be to make the child form proper habits. Those stressed by the Child Health Organization of America are as follows:

A full bath more than once a week.
Brushing the teeth at least once every day.
Sleeping long hours with windows open.
Drinking as much milk as possible, but no coffee or tea.
Eating some vegetables or fruit every day.
Drinking at least four glasses of water a day.
Playing part of every day out of doors.
A bowel movement every morning.

How to get the children to adopt them? Health talks do not suffice. We must not make work of our health teaching in the school, but seek to make it play, for we can get children to do almost anything if it is made play. We should aim to get into their minds that health, too, is a game, with its rules like other games; a game that one can win or lose according as he obeys the rules. The play motive is the most successful one up to the ages of ten or eleven. Unless the child is interested, it is hopeless to attempt to influence him, so we begin if we can with something which is dramatic and which will catch the child's interest, like Chi-Cho, the health clown, the Health Fairy, the Jolly Jester or some of the other dramatic characters of the Child Health Organization, who

introduce health teaching under the guise of amusement or entertainment.

Those who see in this modern movement for the health education only amusement for an hour have not grasped the point. These things are only the beginnings, the first lessons in health—kindergarten lessons if you will—but they are based upon sound psychology; before you can influence you must interest.

Much can be done by health plays, poster exhibits, poster contests with prizes, health rhymes to interest the child, but the best means at all ages is the use of weight and height measurements. This should be done in the school room. It is, of course, necessary that scales should be in the schools and that weights be taken regularly during the school year, usually once a month. The weights for the children of a single room may be entered upon a large chart hung in a conspicuous place. Opposite the initial weight, the average weight for the height is recorded so that the child can see where he stands, and what progress he is making each month.

One must see one of these monthly weighings properly conducted to appreciate their significance. They are made important occasions, and the interest of the children is often intense. The scales are placed at the point of the weight taken the previous month and when a child steps upon the platform eager eyes watch whether the bar will rise or fall, indicating a gain or loss for the month. When the weighing is finished one teacher addresses her children somewhat as follows:

"Now will every child in the room who is up to normal weight for height stand up.

"Children, I could tell it by your looks; by your bright eyes and rosy cheeks, by the work you did in school this month; by the way you play at recess, etc., etc."

All, of course, are delighted and very much pleased with themselves.

"Now, will every child who gained in weight last month, stand."

More words of commendation follow, then the teacher says to a group: "Now won't you tell us how you did it." Many hands go up as each wishes to relate his own personal experience.

When a child is found at the monthly weighing much under weight or not gaining he is anxious to know why. He wants to be in the healthy group. Now is the opportunity to stress the health rules.

Children become vitally interested in their progress. They are then ready to understand and anxious to follow the rules, to submit to medical examination, to have tonsils, adenoids and teeth removed. Health records go home and arouse the interest of parents who will see that a suitable diet and good home habits are of importance.

It is not necessary or desirable that health be taught as a separate subject in the schools, but that it should be brought into the teaching of the various common subjects. It can be introduced illuminatingly into the teaching of such things as history, geography, arithmetic, drawing and composition. A debate could be arranged with the subject: Resolved that the City of San Francisco should furnish half a pint of milk a day at morning recess to every child in the public schools. Think what an opportunity to teach those who take part in such a debate the uses and value of milk. And what a chance to educate the school superintendent if he could be induced to act as one of the judges on such a debate.

Very little apparatus is needed, scales being perhaps the only expensive article. The lecturer remarked that it is not too much to say that the scales have saved the lives of more children than any new device of treatment, medical or surgical. The teacher needs no great special training—mainly enthusiasm and an understanding of children.

Nutrition classes will always be necessary for those so far below normal as to need special attention. Good nutrition classes are impossible without medical assistance. A thorough physical examination is essential. Co-operation with good children's clinics is desirable for investigation and treatment of physical defects and the services of a school nurse are also essential. A desire for improvement must be awakened in the child and this is best done in groups with graphic weight records. Competition is aroused by seeing the progress of other children. Regular attendance is necessary. The school is the best place for nutrition classes. Children should not be taken out of school unless absolutely necessary, but study, exercise and rest should be adjusted to the needs of the child. When he has reached the proper weight for height he may graduate with some ceremony and be given a certificate. To be successful nutrition classes must have a trained enthusiastic, resourceful personnel who understand children.

In conclusion the lecturer submitted three propositions which seem to be very clearly established:

1. Every health movement, which is to bring permanent results, must have an educational basis.
2. The health education of the future must be directed to the teaching of the children.
3. This education must be done in the schools. To initiate this program is the work of the physician. To carry it out is the task of the school authorities.

THE REJUVENATION OF MEDICAL ETHICS

By FRANK B. WYNN, Journal of the Indiana State Medical Association, December 15, 1921, page 422

Dr. Wynn's article should be read and pondered by every physician everywhere, and it ought to be read by the public.

Perhaps there is no phase of medicine concerning which there is so much misinformation as concerning the commonly designated "Code of Medical Ethics."

"It represents a most commendable effort on the part of the intelligent and progressive elements of medicine, to conserve the idealism of the medical past. It seeks to elevate the standards of practice and scientific attainment, of gentlemanly and moral conduct, for the benefit of the patient first of all; for the mutual instruction and elevation of the profession; and in the interest of the public weal."

As the Decalogue was to the ancient Hebrews, so let the profession of medicine find light and guidance in a revival of "The Ten Commandments of Medical Ethics."

The Ten Commandments of Medical Ethics

(Quoted from Dr. Wynn's Article)

I. REVERENCE AND RESPONSIBILITY

Remember thy Creator in the days of professional youth. Bow reverently before the wonderful human body, silk or well, as thou wouldst before a sacred shrine, conscious of thy high duty; resolved to serve to the best of thy power, whether the patient be black or white, prince or pauper, saint or degenerate.

II. HISTORIC APPRECIATION

Honor thy father and thy mother. Likewise give praise to the fathers in medicine, whose rich heritage of scientific and clinical truth has been handed down to thee through centuries of patient toil. Hold fast to that which is good, but let not prejudice, coming out of the past, blind thy vision to the newer truths of medical advancement.

III. KEEPING THE FAITH

Thou shalt not worship the graven images of false practice—of avarice and selfishness which eat at the very heart of medical idealism; of clever

artifice or brazen quackery which knowingly deceives; of erratic isms and cults which tell but half truths, leading the ignorant and unwary astray.

IV. INVIOLABLE CONFIDENCES

Thou shalt not disclose the secrets confided to thy keeping by trusting patients unless they be of criminal or treasonable import. Nor shalt thou abuse the professional intimacy granted to thee by women, which becomes a professional and moral obligation thou shouldst hold inviolate.

V. THE SANCTITY OF LIFE

Thou shalt not hazard life unwarrantably; neither shalt thou shrink before the obvious perils of duty when life is at stake. The unborn shalt thou not destroy except after due consultation, it is deemed advisable for the larger saving of life. Suffer not death to come through neglect in care of the sick, nor from failure in reading, study and counsel to gain the greatest benefit for the patient.

VI. PROFESSIONAL CO-OPERATION

Thou shalt not bear false witness against a worthy professional brother, but seek ever to protect his good name from calumnious attack by misinterpreting laymen. Of thy knowledge give him unstintingly, counseling and co-operating for medical progress.

VII. GENTLEMANLY CONDUCT

Thou shalt not prate of cases nor countenance unseemly boasting of thy achievements in the lay press. Always be a gentleman, let thy conduct be reserved but without cowardice; courteous but free from flattery; dignified but of warm heart; tender in ministration but firm in command; clean of body, speech and mind.

VIII. HONESTY IN BUSINESS

Thou shalt not steal; neither shalt thou make extortionate charges nor deceive by the secret division of fees. As a laborer worthy of hire exact fair compensation, but by open methods and with conscience void of offense toward thy fellowman.

IX. OBLIGATION TO ONE'S OWN

Take heed of the morrow for the sake of thine own flesh and blood. Therefore, shalt thou keep orderly accounts, collecting from the full-handed just recompense for services rendered. To the poor and the families of deserving colleagues, thou shouldst account it a privilege to render faithful attention.

X. PERSONAL AND PUBLIC SERVICE

Remember thou art thy brother's keeper—physically, in the measures and remedies advised for the prevention, alleviation or healing of disease; spiritually, in the cheer thou bringest to heavy hearts and the courage thou givest to halting steps. So walking upright before man, mayest thou shew thyself approved unto God. Thus journeying toward life's end, if not singing with the Psalmist "My cup runneth over," thou wilt at least be sustained by the reflections of "A workman that needeth not be ashamed."

Life Insurance—This issue of the Journal carries the card of Miss Edee H. Percival as a life insurance solicitor. Miss Percival has the endorsement of a number of leading men of our profession as being both capable and interested in giving to physicians the very best advice in placing life insurance policies.

Radiologists Liable—The Supreme Court of Arkansas has recently held that radiology (roentgenology) is a highly technical profession and that the radiologist, and not the physician, is liable for his acts. A more extensive review of this decision is published in a recent number of the Literary Digest.

EXTENSION WORK

The following additions have been made to the Extension Lecture courses offered by members of the State Society to local societies: (See November Journal for other lectures, page 450.)

MILEY B. WESTON, M.D.,
686 Flood Building, San Francisco.

I—**Urethritis and Its Complications.** (Illustrated by lantern slides.)
1. The Anatomy and physiology of the urethra.
2. Etiology: specific and non-specific urethritis.
3. Pathology.
4. Symptoms: acute and chronic.
5. Complications: stricture, prostatitis, vesiculitis, verumontanitis, cowperitis, stricture of ejaculatory ducts, epididymitis, etc.
6. Treatment: medical and surgical.

II—**Prostatism.** (Illustrated by lantern slides.)
1. The anatomy and physiology of the prostate.
2. Prostatic calculi.
3. Prostatitis: (a) acute; (b) chronic.
4. Tuberculosis of the prostate.
5. Prostatic hypertrophy, benign.
   (a) Etiology and pathology.
   (b) Symptoms.
   (c) Diagnosis.
   (d) Treatment: (1) Palliative; (2) Operative.
6. Cancer of the prostate.
   (a) Diagnosis.
   (b) Treatment:
      (1) Radium applications.
      (2) Operation: Conservative, Radical.

III—**Diseases of the Bladder:** Symptoms and Treatment. (Illustrated by lantern slides.)
1. The anatomy and physiology of the bladder.
2. Malformations of the bladder: diverticula, multiple bladders, fistulae, etc.
3. Disturbances of urination:
   (1) Mechanical obstructions;
      (a) Hypertrophy of prostate.
      (b) Contracture of vesical neck.
      (c) Median bar.
      (d) Hypertrophy of the trigone.
      (e) Tumors.
      (f) Stones, foreign bodies, etc.
   (2) Incontinence;
      (a) Nocturnal enuresis.
      (b) Parodoxical incontinence (C. N. S.).
      (c) Impaired vesical sphincters.
   (3) Infections (cystitis);
      (a) Acute, subacute and chronic.
      (b) Ulcerative and interstitial.
      (c) Tuberculous.

IV—**Diseases of the Kidney and Ureter:** Symptoms and Treatment. (Illustrated by lantern slides.)
1. The surgical anatomy and physiology of the kidney and ureter.
2. Congenital malformations.
3. Traumatic injuries.
4. Hydronephrosis.
5. Movable kidney.
6. Stones, tumors, etc.
7. Pyogenic infections: Pyelitis, Pyelonephritis, etc.
8. Tuberculous.
9. Kidney impairment (back pressure from prostate, etc.).
10. Kidney suppression (anuria).

"The Cornell Pay Clinic may not have employed a press agent, but the publicity achieved by it was very impressive. The arguments advanced to justify the establishment of such a clinic are of the most specious character, and assume first of all that the medical profession is composed of morons.

"Sometimes one does wonder, we are bound to confess, whether the aforesaid assumption is not the correct one."—From The Medical Times, January, 1922.

I pity no man because he has to work. If he is worth his salt, he will work. I envy the man who has a work worth doing, and does it well. There never has been devised, and there never will be devised, any law which will enable a man to succeed save by the exercise of those qualities which have always been the prerequisites of success—the qualities of hard work, of keen intelligence, of unflinching will.—Theodore Roosevelt.

COUNTY SOCIETIES

Alameda County Medical Association (reported by Dr. C. L. McVey, secretary)—The society met December 19, 1921, in the Oakland Health Center. Q. O. Gilbert, M. D., read a paper on "Some Technical and Therapeutic Considerations in Blood Transfusions." He briefly reviewed the history of blood transfusion, emphasizing the points in technic of interest in relation to present procedures.

Special emphasis was laid upon the selection of a donor, and the necessity, not only of grouping the donors and patients, but also that it is quite essential to test the donor and donee directly against each other, even though they are of the same group. The condition of para iso haemagglutins was discussed.

While the usual conditions for transfusion were discussed, special emphasis was placed on the use of transfusions to combat the toxemia and anemia occurring in acute infections. The author considers the whole blood transfusion without the use of anti-coagulants the best.

C. O. Edwards, D. D. S., read a paper on "The Method of Rebuilding the Muscles of Facial Expression After the Loss of Natural Teeth." Lantern slides served to illustrate the important points in the paper. Before the operation of extraction of teeth is performed, measurements of the face should be on record. Measure in millimeters the distance from the chin to nose, from chin to center of pupils of the eyes, from cutting edge of upper incisor teeth to pupils of the eyes, and from lower edge of upper lip to eyes. The next step is to make a templet from a heavy card, mark and cut out to fit over forehead, nose, lips and chin at the median line, so that the muscles of the face can be accurately re-established. A line is now drawn on the natural teeth to mark the position of the lip at rest, when speaking, smiling and laughing. The next step is to take plaster impressions like those used by orthodontists, of the upper and lower teeth. After operating, the natural teeth are sterilized and placed in these impressions and a model made giving us the original in the same relative position as they were in the mouth.

The patient should exercise the muscles of the face frequently. Artificial dentures should be completed and worn within from one to three weeks after the extraction.

The society is proposing a change in the constitution relative to the election of applicants to the society, to read as follows:

Article IV, Section 1. Every legally registered physician having resided and practiced in Alameda County for one year next preceding the date of making application who is of good moral and professional standing, and who does not support or practice or claim to practice any exclusive system of medicine, shall be eligible for membership.

The following officers were elected for the ensuing year: Dr. E. E. Brinckerhoff, president; Dr. Pauline S. Nusbaumer, vice-president; Dr. C. L. McVey, secretary-treasurer.

Alameda County Medical Association—Officers for 1922: President, Dr. E. E. Brinckerhoff; vice-president, Dr. Pauline Nusbaumer; secretary-treasurer, Dr. C. L. McVey; councillors—Dr. L. P. Adams, Dr. Daniel Crosby, Dr. A. M. Smith, Dr. A. M. Meads, Dr. G. G. Reinle, Dr. W. H. Strietmann; delegates—Dr. C. L. McVey, Dr. P. S. Nusbaumer, Dr. W. H. Strietmann; alternate delegates—Dr. L. P. Adams, Dr. W. A. Clark, Dr. C. A. De Puy, Dr. R. A. Glenn, Dr. Gertrude Moore, Dr. C. W. Page.

Fresno County Medical Society (reported by Dr. Thos. F. Madden, secretary)—The January meeting, which was the annual meeting, resulted in the election of the following officers for the year 1922: President, Dr. G. W. Walker; first vice-president, Dr. F. J. Tillman; second vice-president, Dr. A. D. Ellsworth; secretary, Dr. Thos. F. Madden; treasurer, Union National Bank of Fresno; assistant secretary, Dr. F. K. Pomeroy; Board of Governors, Dr. D. H. Trowbridge; delegates, Drs. J. R. Walker, W. W. Cross, H. J. Craycroft; alternates, Drs. J. H. Pettis, Guy Manson, A. B. McConnell.

Dr. Edmund Butler of San Francisco presented the subject of "Brain Injuries—Mechanics—Prognosis and Treatment." Drs. Clinton Collins, F. J. Tillman, L. P. Fleming and D. H. Ransom joined in the discussion of the subject.

The society expressed in the form of a resolution the deep regret of its members at the death of Dr. A. R. Nicholson on December 18. The sympathy of the society was extended to the bereaved family, and a copy of the resolution placed upon the society's minutes. Dr. Nicholson was one of the pioneer members of the Fresno County Medical Society, took an active interest in its welfare and the welfare of the community in which he served as a beloved physician.

The surgical staff of the Fresno County Hospital is holding bi-monthly meetings, each meeting conducted by a different member of the staff. Some of the meetings are devoted to bedside clinics, and all are working for the good of the profession, hospital and the public.

Merced County Medical Society (reported by Brett Davis, M. D., secretary)—The regular monthly meeting for January was held in the office of the secretary. There were seven members of the society present and two visitors. Roland B. Tupper, M. D., of the Fresno County Society presented a paper on "Basal Metabolism and the Thyroid Gland."

The improved appearance of the California State Journal of Medicine and the increase in value of its medical literature was the cause of comment by members of the society.

Wm. C. Cotton, M. D., has been appointed County Health Officer of Merced County to succeed J. L. Mudd, M. D., who has resigned.

Monterey County (reported by Dr. T. C. Edwards, secretary)—At the annual meeting held January 7, 1922, the following officers were elected for the year 1922: President, Chas. T. Bullard, M. D., King City; vice-president, Geo. A. Starbird, M. D., Soledad; secretary, T. C. Edwards, M. D., Salinas; treasurer, John A. Beck, M. D., Salinas; delegate to the State Meeting, Henry J. Koenecke, M. D., Salinas; alternate to the State Meeting, W. R. Reeves, M. D., Salinas.

The History of Medicine—Dr. C. D. Ball of Santa Ana is writing a history of the pioneer physicians of Orange County. The council of the State Medical Society is interested in securing histories of this type of the organizers of medicine by counties throughout the State of California. Any physician who wishes to handle this matter for his own county is requested to communicate with the State secretary.

Riverside County Medical Society (reported by Thomas A. Card, M. D., secretary)—The January meeting was held in the Chamber of Commerce rooms with twenty-six members and sixteen guests present, and twenty members absent.

The site for the new Community Hospital has been definitely chosen, and it is the purpose of the directors to begin building very soon.

W. B. Wells, M. D., has resigned as City Health Officer, and his successor has not been appointed.

Ethel Watters, M. D., of the State Board of Health, in conjunction with the Well Baby Conference, is arranging to hold a series of clinics in various towns to which mothers may bring their babies for examination. Talks to mothers on the care of babies and proper diet will be given. Patients who need medical advice will be referred to their family physician.

The Department of Hygiene of Riverside County is working in conjunction with the physicians of various towns in an effort to make medical examinations of all school children. The Department of Hygiene proposes to install the hot school lunch routine; teach health in schools as part of the daily program; to interest the children in the lives of great physicians, and acquaint them with quarantine laws and health regulations.

A newspaper clipping from Riverside quotes the Medical Society as making an effort to secure the services of a full-time health officer for Riverside County.

Sacramento County (reported by Dr. G. J. Hall)—The annual meeting of the Sacramento Society for Medical Improvement was held on Tuesday, December 20.

An amendment to the Constitution and By-laws was passed. Dr. G. J. Hall was re-elected secretary. Six directors were elected for the coming year, as follows: Drs. Schoff, Howard, Dillon, Foster, Pope and Henderson. Delegates to State Society, E. C. Turner and E. T. Redison, Jr. Two alternates were elected in the persons of Drs. James and Drysdale. One member of executive committee to be elected; result, Dr. S. E. Simmons re-elected.

The annual dues were changed from $12 a year to $15 in order to send the secretary to all State Medical meetings in the future. Carried.

At a special meeting called January 4, 1922, for the election of a president and vice-president, Dr. G. P. Dillon was elected president and Dr. B. F. Howard, vice-president, by the board of directors.

San Bernardino County Medical Society (reported by Dr. E. J. Eytinge, secretary)—The January meeting was held at the County Hospital with thirty members and ten visitors present and forty-one members absent. Doctors W. A. Jones, W. S. Davis and C. Van Zwalenburg discussed the "Eary Diagnosis of Intussusception." Dr. C. P. Thomas of Los Angeles presented the subject of "The Treatment of Cancer of the Anus, Rectum, and Colon." Discussions of these papers were opened by Dr. C. G. Hilliard and Dr. P. M. Savage. The staff of the County Hospital exhibited and discussed a number of clinical cases.

San Francisco County Medical Society (reported by Dr. LeRoy H. Briggs, secretary)—The annual meeting of the society was held on December 13, when the following officers were elected: President, Dr. Saxton Pope; first vice-president, Dr. Rene Bine; second vice-president, Dr. Mary E. Botsford; secretary-treasurer, Dr. LeRoy H. Briggs; librarian, Dr. Leo Eloesser; directors, Drs. Rene Bine, W. W. Boardman, W. R. P. Clark, H. W. Gibbons, Sol. Hyman, Wm. Ophuls, R. K. Smith; delegates, Drs. W. C. Alvarez, M. O. Austin, W. W. Boardman, Leo Eloesser, G. H. Evans, W. S. Franklin, H. P. Hill, Sol. Hyman, E. S. Kilgore, Lovell Langstroth, Howard Morrow, Wm. E. Stevens, W. I. Terry, V. G. Vecki, C. F. Welty; alternates, G. G. Moseley and Harry Spiro.

The scientific program of the annual meeting included a paper on "Etiology and Treatment of Asthma in Children," by Dr. A. H. Moore, and "Nose and Throat Pathology as Etiological Factors in Asthma," by Dr. E. C. Sewall. These papers were discussed by Drs. A. J. Houston, S. H. Hurwitz, C. F. Welty, Sanford Blum and P. H. Pierson.

At a special meeting held on December 30, Dr. Julius Rosenstirn addressed the society on "The Relation of Parasitic Infection to the Growth of Cancer in Animals."

San Francisco County Medical Society—President Saxton Pope and Secretary LeRoy H. Briggs have issued the following circular to all physicians in San Francisco:

"The Medical Society is a private, voluntary organization. It is an association in which the best medical men should be. It stimulates the mind to greater effort and to raise medical standards, both ethically and scientifically. Active membership in the Medical Society wears off the sharp edges of professional jealousy; through it one becomes respectful of his professional brother—discovering the good points of the other man. An active part in the Medical Society will make a more liberal and diligent student, practitioner, or leader. The association of medical minds promotes initiative in research work and the exchange of ideas. Membership in the Medical Society popularizes progressive and medical thought. The medical men are so highly specialized, that if they cannot bring themselves into a harmoniously organized group for study, no one can do it for them. Having chosen association with such a group, there is no question but that the affiliation gives prestige in return."

San Diego County Medical Society (reported by Dr. Robert Pollock)—The annual dinner of the Medical Society was held at the San Diego Hotel on the evening of December 13, 1921. After an enjoyable banquet the president announced the results of the election of officers for 1922:

President, W. W. Crawford, M. D.; vice-president, J. F. Churchill, M. D.; secretary, Geo. B. Worthington, M. D.; treasurer, C. L. Stealy, M. D.; for councillors, M. H. Arnold, M. D., J. E. Jennison, M. D., H. A. Thompson, M. D.; for delegates, C. M. Hosmer, M. D., T Coe Little, M. D., J. C. Yates, M. D.; for alternates, J. C. E. Nielsen, M. D., E. H. Crabtree, M. D.; for Milk Commission, Frances M. Allen, M. D., R. A. Kocher, M. D.; directors of the medical library, M. H. Arnold, M. D., F. A. Burton, M. D., T. Coe Little, M. D., H. P. Newman, M. D., Robt. Pollock, M. D., L. H. Redelings, M. D., P. C. Remindino, M. D., C. L. Stealy, M. D., H. A. Thompson, M. D., C. H. McConaughy, D. D. S., H. L. Murdock, D. D. S., Guy V. Smith, D. D. S.; secretary-treasurer, C. L. Stealy, M. D.

The January meeting was devoted to the reports of the retiring officers and the installation of the officers for 1922. Humorous case reports were made by men of eminence in the profession.

San Diego members are planning to attend the Yosemite meeting of the State Society in liberal numbers.

Group Medicine: One of the recent meetings of the San Diego County Medical Society was devoted to the discussion of Group Medicine. The subject was discussed by Drs. Donald Frick, Charles D. Lockwood, H. A. Johnston and others. A rather full report of this meeting will be found in Vol. 7, No. 19 of the Bulletin of the San Diego County Medical Society. Persons particularly interested in the subject should read this Bulletin.

San Joaquin County Medical Society; Annual Meeting (reported by Dr. Dewey R. Powell, secretary)—The annual meeting of the San Joaquin County Medical Society was held in the White Room of the Hotel Stockton on Friday evening, December 9, at 7 o'clock, at which time a delightful dinner was served and the members enjoyed the first social evening held by the Medical Society in many years. The following members were elected directors for the ensuing year:

Dr. C. R. Harry, Dr. F. P. Clark, Dr. R. T.

McGurk, Dr. J. D. Dameron, Dr. L. R. Johnson, Dr. B. J. Powell, Dr. D. R. Powell, Dr. Hudson Smythe and Dr. Margaret Smythe. The following officers were chosen from the board of directors: Dr. Hudson Smythe, president; Dr. J. D. Dameron, first vice-president; Dr. Margaret Smythe, second vice-president, and Dr. Dewey R. Powell, secretary and treasurer.

Dr. Saxton Pope, Assistant Clinical Professor of Surgery at the University of California and president-elect of the San Francisco County Medical Society, spoke on "Hunting Wild Game with the Bow and Arrow," and illustrated his remarks by numerous lantern slides. He told of his first interest with the bow and arrow, due to his association with the Indian Ishi, the last of the Yani tribe, and how he had been taught by Ishi both to shoot and to hunt. He showed slides of various types of wild game, such as squirrels, quail, wildcats, mountain lions and deer which had been brought down by the bow and arrow, and vividly described his hunt in Yellowstone Park, where he and his companions secured five grizzly bears, including one 1000-pound bear known as the largest in the United States.

The social nature of the annual meeting was voted quite a success and it was the consensus of opinion that the society should hold at least one social evening each year.

Santa Clara County Medical Society (reported by Dr. J. L. Pritchard, secretary)—The December meeting was the annual business meeting of the society. The following officers were elected for 1922:

President, R. T. Wayland; first vice-president, F. S. Ryan; second vice-president, R. G. Reynolds; third vice-president, Jonas Clark; treasurer, H. C. Brown; secretary, E. P. Cook; councillors, J. J. Beattie, T. L. Blanchard, C. E. Saunders; delegates, G. L. Barry, C. Wayland, J. H. Shephard, C. E. Saunders; alternates, J. S. Staub, D. Wilson, F. S. Ryan, G. A. Gray.

Dr. J. Underwood Hall was transferred to San Francisco and Dr. Chas. W. Delaney transferred to Altoona, Pennsylvania.

The O'Connor Sanitarium was recently overhauled, the laboratory adding all necessary equipment to do first-class work. The hospital has also provided a record room and installed a record clerk.

Santa Cruz County Medical Society; Annual Meeting (reported by Dr. James Cutter)—The annual meeting of the Santa Cruz County Medical Society was held December 17 with nine members present. The officers elected for the ensuing year were: Dr. H. G. Watters, president; Dr. Stanley Dowling, first vice-president; Dr. James B. Cutter, second vice-president, Dr. A. N. Nittler, secretary and treasurer; Dr. P. T. Phillips, delegate to the State Society; Dr. E. Lee Burch, alternate; Dr. J. B. Cutter, corresponding editor; Dr. S. C. Rodgers, censor for 1924.

Dr. Cothran discussed "The Effects of Alcohol Upon the Gastric Mucosa and the Cerebral Cortex of Rats."

It was voted to hold future meetings every three months at Watsonville.

Stanislaus County (reported by Dr. E. F. Reamer, secretary)—The annual meeting was held on December 15 at the Modesto Hotel. The usual annual dinner and business meeting were held and no scientific papers were presented. There were fifteen members present and twnty-three absent, the large number of absentees being explained by the disagreeable weather. The following officers were elected for the ensuing year:

President, Dr. A. M. Field; vice-president, Dr. J. K. Ransom; secretary-treasurer, Dr. R. E. Maxwell; censor three years, Dr. F. R. DeLappe; delegate to State Society meeting, Dr. E. F. Reamer; alternate, Dr. John A. Cooper.

Certain members of the society requested information as to the advisability of changing their by-laws so as to require six months' residence before a candidate shall be eligible for active membership.

Note: The answer from the State Society is as follows: It seems to be the general opinion among our most experienced men that a time limit is not adequate as a safeguard and is not necessary when more thorough investigation is made prerequisite to membership. It is suggested that if a change in the by-laws is to be made, a better change would be to provide that no physician could be elected to active membership in any county society until his application, in addition to the usual procedure, had received the certificate of his licensure and creditable standing with the State Board of Medical Examiners and the approval of the State Society office, which carries with it a review of the records of the A. M. A. headquarters in Chicago.

NOTICES

SECTION ON ANESTHESIOLOGY OF THE CALIFORNIA STATE MEDICAL SOCIETY AND THE PACIFIC COAST ASSOCIATION OF ANESTHETISTS.

By Eleanor Seymour, M. D., Secretary-Treasurer, 1329 South Grand Ave., Los Angeles.)

The Pacific Coast Association of Anesthetists will hold its first Scientific Meeting at Yosemite Park, Monday and Tuesday, May 15-16, 1922, in conjunction with the meeting of the Section on Anesthesiology of the California State Medical Society.

A splendid scientific program of pertinent papers is in the making for this occasion and the sessions will offer those in attendance every opportunity to acquire an intimate knowledge of what is best in the science and practice of anesthesia.

The Pacific Coast Association of Anesthetists was founded at Coronado in May, 1921, through the united efforts of the Southern and Northern California Societies of Anesthetists and other interested anesthetists of the Pacific Coast and Rocky Mountain States. At that time the constitution was adopted and officers for the first scientific meeting were elected.

Membership in the Pacific Coast Association of Anesthetists is open to all licensed and qualified members of the medical and dental professions, as well as to research workers holding doctorates of similar standing, who are interested in advancing the specialty of anesthesia.

The meeting will be held at Yosemite Park, and as a large attendance is expected you are advised to make your reservations now. You are afforded an opportunity of a wonderful sightseeing trip, as well as an unusual scientific meeting.

If you wish to present a paper during the meeting or section, kindly notify the secretary at once, giving the title and brief abstract of same.

Send for and fill in the details of a membership application and return it with your check or money order for the annual dues ($5), so that your membership card may be sent you in advance of the meeting. Also be sure and send the names and

addresses of as many prospects for membership as you may know of.

Details regarding the annual dinner of the association and other entertainments will be sent later with the preliminary program.

The following officers and executive committee will be in charge of the Yosemite meeting: George P. Waller, president; Mary E. Botsford, vice-president; Eleanor Seymour, secretary-treasurer; executive committee—Walter R. Crane, Caroline B. Palmer, R. L. Charles, D. E. Hoag, L. H. Maxson and Louise A. Oldenbourg.

The officers and executive committee will do everything they can to make this meeting interesting, instructive and enjoyable. Your cordial cooperation and support are solicited in launching the Pacific Coast Association of Anesthetists and the Section on Anesthesiology on successful careers for the benefit of all concerned.

This is an opportunity for all anesthetists of the Pacific Coast and Rocky Mountain States to find out what their associates know about the specialty of anesthesia and to exchange researches and clinical experiences, for the benefit of their specialty and in the interest of better surgery.

Industrial Accident Work—The Industrial Accident Commission under date of December 7 have issued a form letter to all physicians in the State, giving details regarding the requirements of the law and of the Industrial Accident Commission in the discharge of their duty. This letter is too long for publication in the Journal, but every physician engaged in work of this character and who has not already received a copy is advised to write to the Industrial Accident Commission for one. Particular attention is called to Section 53 of the Industrial Accident law, which reads in part as follows: "Every physician or surgeon who attends any injured employe, is hereby required to file with the commission, under such rules and regulations as the commission may from time to time make, a full and complete report of every injury to an employe arising out of or in the course of his employment and resulting in loss of life or injury to such person."

Popular Medical Lectures of Stanford Medical School—The fortieth course of these popular lectures will be given at Lane hall as follows: January 13, "The Basis of Modern Medicine," by Dr. William Ophuls; January 27, "The Attitude of the Public Toward the Blind," by Miss Katherine Foley; February 10, "The Treatment of Deformities Following Infantile Paralysis," by Dr. Arthur L. Fisher; February 24, "The Control of Botulism," by Dr. E. C. Dickson; March 10, "The Truth about Vivisection," by Mr. Ernest H. Baynes; March 24, "Present Day Methods of X-ray Diagnosis," by Dr. W. Edward Chamberlain.

Research in Homeopathic Medicine—The California State Homeopathic Medical Society has appointed Dr. R. W. F. Winnard, Dr. Milton A. Barndt, Dr. Edward P. Clark, Dr. George H. Martin, Dr. Robert F. Knoll, Dr. James D. Miller, Dr. F. H. Cookinham, Dr. Edgar H. Howell, Dr. Marion B. McAulay, Dr. Joseph Pollia and Dr. Henry L. Stambach as a committee on research for the California State Homeopathic Society.

The Western Section of the American Laryngological, Rhinological and Otological Society (reported by Dr. Grant Selfridge).—This section will hold a meeting in the San Francisco County Medical Society rooms on February 23. The morning will be devoted to surgical clinics at Stanford Hospital, and the afternoon to the discussion of scientific papers.

GENERAL SESSION AND SECTION OFFICERS FOR THE 1922 MEETING OF THE STATE SOCIETY

The list of the officers of the general sessions and the various sections of the State Society is published below, so that members desiring to contribute papers may have the names and addresses of the proper officers of the section in which they are interested. Members desiring to present papers should communicate without delay with the chairman and secretary of the appropriate section, because the program is getting well under way and will be closed and go to press the first week in February.

The Secretary of the State Society, as chairman of the General Program Committee, invites correspondence and suggestions regarding any phase of the 1922 program.

GENERAL SESSIONS

Chairman, Dr. John H. Graves, President of the Society, 977 Valencia Street, San Francisco.
Secretary, Dr. W. E. Musgrave, Chairman of the Program Committee, 912 Butler Building, San Francisco.

SECTION ON TECHNICAL SPECIALTIES

Chairman, Dr. Ray Lyman Wilbur, President Stanford University.
Secretary, Dr. Charles T. Sturgeon, Merritt Building, Los Angeles.

SECTION ON MEDICAL ECONOMICS, EDUCATION AND PUBLIC HEALTH

(League for the Conservation of Public Health)

Chairman, Dr. Dudley Smith (President League for the Conservation of Public Health), Thomson Building, Oakland.
Secretary, Dr. W. T. McArthur (Secretary League for the Conservation of Public Health), Security Building, Los Angeles.

SECTION ON INDUSTRIAL MEDICINE AND SURGERY

Chairman, Dr. E. W. Cleary, 177 Post Street, San Francisco.
Secretary, Dr. Packard Thurber, 906 Black Building, Los Angeles.

SECTION ON RADIOLOGY

(Roentgenology and Radium Therapy)

Chairman, Dr. Albert Soiland, 527 West Seventh Street, Los Angeles.
Secretary, Dr. H. E. Ruggles, Butler Building, San Francisco.

SECTION ON PATHOLOGY AND BACTERIOLOGY

Chairman, Dr. William Ophuls, Stanford University Medical School, San Francisco.
Secretary, Dr. Roy W. Hammack, Brockman Building, Los Angeles.

SECTION ON GENERAL MEDICINE

Chairman, Dr. Joseph M. King, Brockman Building, Los Angeles.
Secretary, Dr. E. S. Kilgore, 391 Sutter Street, San Francisco.

SECTION ON PEDIATRICS

Chairman, Dr. William Palmer Lucas, University Hospital, San Francisco.
Secretary, Dr. Hugh K. Berkley, Brockman Building, Los Angeles.

SECTION ON NEUROPSYCHIATRY

Chairman, Dr. Walter F. Schaller, 909 Hyde Street, San Francisco.
Secretary, Dr. W. B. Kern, Brockman Building, Los Angeles.

SECTION ON GENERAL SURGERY

Chairman, Dr. Charles D. Lockwood, 295 Markham Place, Pasadena.
Secretary, Dr. Edmund Butler, Butler Building, San Francisco.

SECTION ON EYE, EAR, NOSE AND THROAT

Chairman, Dr. Frank A. Burton, Watts Building, San Diego.
Secretary, Dr. Harvard McNaught, Butler Building, San Francisco.

SECTION ON UROLOGY

Chairman, Dr. George W. Hartman, 999 Sutter Street, San Francisco.
Secretary, Dr. Louis Clive Jacobs, 462 Flood Building, San Francisco.

SECTION ON ORTHOPEDIC SURGERY

Chairman, Dr. W. W. Richardson, Brockman Building, Los Angeles.
Secretary, Dr. G. J. McChesney, Flood Building, San Francisco.

SECTION ON ANESTHESIOLOGY

Chairman, Dr. Mary E. Botsford, 807 Francisco Street, San Francisco.
Secretary, Dr. Eleanor Seymour, 1329 S. Grand Ave., Los Angeles.

SECTION ON GYNECOLOGY AND OBSTETRICS

Chairman, Dr. Harry M. Voorhees, Brockman Building, Los Angeles.
Secretary, Dr. L. A. Emge, Stanford University Hospital, San Francisco.

HOSPITALS

SAN FRANCISCO HOSPITAL SURGICAL CLINICS

The public surgical clinics (Colloquia) held at the San Francisco Hospital, Potrero avenue and Twenty-second street, every Thursday morning from 9:00 to 12:00, by members of the staff of the Stanford University Medical School and San Francisco polyclinic, which were omitted during the holidays, were resumed on Thursday, January 12, the clinic being given by Dr. Emmet Rixford.

A Case of Spiral Fracture of the Humerus from Throwing a Baseball.

Dr. Rixford stated he had previously operated upon but one case with similar etiology, and this a number of years ago. In view of the great number of men and boys who play baseball, it is remarkable that this fracture does not occur more commonly.

Spiral fractures of the long bones are always the result of rotatory or twisting force. A right-handed twist always produces a right-handed spiral and a left-handed twist always produces a left-handed spiral. In the spiral fracture of the humerus produced by throwing a baseball, if the player is right-handed the right humerus is subjected to violent external and, therefore, left-handed torsion, uncomplicated by other forces. Here we have the purest form of spiral fracture practically without longitudinal displacement and without stripping up of the periosteum. In the typical spiral fracture the spiral fissure may extend as much as twice around the bone as was observed in the first case mentioned, the bone being finally separated into two fragments by a substantially vertical fracture uniting two adjacent limbs of the spiral. The periosteum is torn along the spiral part of the fracture, but not along the vertical component, because as the bone breaks it folds upon the vertical part of the fracture as on a hinge. For this reason, and in view of the form of the fracture lines and surfaces, it is evident that if the fracture is accurately reduced the bones fit together with mathematical nicety and considerable firmness, stability being lacking only in the direction of the rotation which produced the fracture. Therefore, if a splint can be so applied as to resist this rotation, displacement will not recur.

Since it is practically impossible to adjust such a fracture with such a degree of nicety as will secure the stability as above described without open operation, it is logical to treat all such fractures, except in young children, by the open method, unless there is some contraindication to operation in general.

In the operation, the aim should be to identify and locate the spiral element of the fracture, to cut down upon it, remove chips of bone, bits of muscle, fascia, etc., which interfere with accurate reduction; drill the bones at points which will be horizontally opposite each other across the spiral after reduction, passing a single silver wire, reducing the fracture and tightening the wire. This may be done in most instances without disturbing the periosteum in the least, and without producing more than a minimum of traumatism of the soft parts.

In the typical spiral fracture there is, therefore, no necessity of implanting large foreign bodies, Lane or other plates, screws, etc. The risk of infection, which is practically the only objection to operation in such cases, is minimized by this technique; specifically, by avoidance of unnecessary truama, stripping up periosteum, and implantation of more than a minimum of foreign material. Silver wire has on its part some antiseptic capacity, and is readily incorporated in the bone and almost never requires to be removed. It is much more reliable than kangaroo tendon.

The above facts and procedures were illustrated by the case in hand. After dressing the arm it was put up in a light splint and bound to the side, the forearm flexed across the abdomen.

Another argument for the above technique in the management of spiral fracture of the humerus, is the fact that the spiral not rarely follows the groove of the radial nerve (musculo-spiral), which nerve may most safely be protected against compression by callus, etc., by such an operation. If advisable, as it may be in some cases, a layer of fascia or muscle can be interposed between the nerve and the line of the fracture. If adjustment of the fracture is mathematically perfect, very little callus will be thrown out or will be required.

Tumor on the Right Side of the Neck, Just Above the Clavicle—Case for Diagnosis.

A man of sixty-three, beginning to lose flesh, somewhat below par in health and vigor, presented a tumor of rapid growth, the size of a man's fist, beneath the sterno-mastoid muscle, lateral to the great vessels, free from the clavicle, not evidently pulsating; not affecting the pulsation in the radial artery nor interfering with the venous or lymphatic return from the arm. No apparent engorgement of veins of the head; no interference with pulsation of carotid or temporal arteries; no interference with sensation or motion in the arm. The tumor was evidently infiltrating, attached to the deeper structures of the lateral aspect of the neck. No fever, growth not tender.

Malignant or inflammatory goiter ruled out by the position of the tumor lateral to the carotid artery; age of patient, absence of pre-existing goiter. Hodgkins' disease and lympho-sarcoma ruled out by the fact that the tumor was single and not multiple; fixed and not movable; blood picture normal. Absence of lymphomata in axilla, opposite side of the neck, etc. History of continuous enlargement of the growth without intermission such as is commonly present in Hodgkins' disease; also absence of intermitting fever; blood Wassermann negative.

If carcinoma, the primary tumor was most likely to be found in the œsophagus, lung, or some abdominal organ.

Carcinoma of the lung seemed unlikely, because of the absence of cough, sputum, and pulmonary signs. Aneurism excluded by the absence of pulsation in the tumor; absence of pain; as from bone erosion or pressure on nerves; absence of interference with pulsation in radial artery; absence of evidence of bronchial compression; rasping cough, stenotic breathing, etc.

Carcinoma of the abdominal organs only rarely gives rise to metastatic tumors in the right side of the neck.

The clinical history was completely negative as to symptoms of carcinoma of the stomach, gall-to œsophagus and larynx. Voice normal; deglutibladder or intestine; also negative with reference tion also normal.

In view of the above, the most probable diagnosis was carcinoma of the lymph glands of the neck, secondary to primary tumor in the œsophagus, but œsphogoscopy, by Dr. H. B. Graham, showed the entire œsophageal mucous membrane to be free from ulceration or tumefaction.

Fluoroscopy, by Dr. Chamberlain, showed the œsophagus to be normal in form and motility except for a lateral deviation in the upper chest, where plates showed an indefinite shadow suggesting mediastinal tumor slightly displacing the œsophagus.

Exploratory incision, lifting off the sterno-

mastoid muscle, showed the tumor to be infiltrating and completely obstructing the jugular vein. The finger introduced beneath the clavicle and sternum showed the tumor to be free from the anterior chest wall and clavicle. It showed also an extension of the tumor downward into the chest beyond the reach of the finger.

The major portion of the tumor of the neck was then cut away, including the obliterated portion of the jugular vein. The pneumogastric nerve was found to be surrounded by tumor. It had evidently not been compressed sufficiently to interfere with motor function of the larynx.

On cross section, the tumor appeared to be sarcoma, possibly of fascial origin, but contained large areas of yellowish necrosis. Histological examination of the tumor by Dr. Ophuls showed the tumor to be carcinoma (malignant epithelioma), its origin not determined.

St. Joseph's Hospital of San Francisco announces improvements—Plans have been completed for the early construction of a new hospital of 300 beds. Staff organization has been provided with Dr. A. S. Musante as chief of the staff; Dr. W. C. Mackintosh, vice-president; Dr. L. Overstreet, secretary; Dr. F. C. Keck, treasurer; Drs. C. E. Taylor, Wm. Quinn, P. Collischonn, T. I. Janes, A. S. Musante and Wm. Mackintosh, executive council.

Children's Department of the Santa Barbara Cottage Hospital—The Cottage Hospital in Santa Barbara is in receipt of a gift of $50,000 for the establishment of a Children's Ward, and Mr. Knapp announces that he is going to raise additional money to build a new Nurses' Home for the hospital shortly.

Santa Barbara Cottage Hospital Clinic Day—Recently the Cottage Hospital staff carried out a whole day of intensive review and clinics, with a large number of physicians present. During the morning Surgical Clinics included five laparotomies by various members of the staff; the nose and throat men provided demonstrations and operations; an hour was given to demonstrations of X-ray work and of radium therapy; and the Chemical Laboratory demonstrated various blood chemical methods. Luncheon was served in the hospital. During the afternoon a medical program was given consisting of papers or clinical demonstrations by ten medical men of the staff. Some of the material presented consisted of cases or post-mortem specimens, and lantern slides of congenital syphilis, diabetic gangrene treated with sodium citrate; leprosy, heart block and linitis plastica. Also, during the afternoon major surgical procedures and operative eye work were carried on. The day closed with a banquet by the Santa Barbara County Medical Society to which the visitors were invited.

A Clinic Day of this character acquaints the various members of the staff with the work of their colleagues, serves as a decided stimulus for each man to improve the character and the technique of his work; it demonstrates the fact that even in smaller communities, good work over a considerable range of subjects is being done, and it further promotes a spirit of harmony and of team play among the members of the staff, which shows itself repeatedly in the every-day routine of hospital work.

The success of this undertaking by the staff of the Cottage Hospital and the compliments received from the physicians from various parts of the county who were present, is such, that they are already looking forward with enthusiasm to putting on a similar program within the coming year.

BOOKS RECEIVED

History of Medicine, With Medical Chronology, Suggestions for Study and Bibliographic Data, by Fielding H. Garrison, M. D., Lieutenant-Colonel, Medical Corps, U. S. Army, Surgeon-General's Office, Washington, D. C. Third Edition, Revised and Enlarged. Octavo of 942 pages with 257 portraits. W. B. Saunders Company, Philadelphia and London, 1921. Cloth, $9 net.

1920 Collected Papers of the Mayo Clinic, Rochester, Minn. Octavo of 1392 pages, 446 illustrations. Philadelphia and London: W. B. Saunders Company. Cloth, $12 net.

Pediatrics and Orthopedic Surgery. Practical Medicine Series. Edited by Edwin W. Ryerson, M. D., with the collaboration of Robert O. Ritter, M. D. Chicago: The Year Book Publishers. 1921.

Vice and Health (Problems, Solutions). By John Clarence Funk, M. A., LL. B. Philadelphia and London: J. B. Lippincott Company.

The Blood Supply to the Heart in its anatomical and clinical aspects. By Louis Gross, M. D., C. M. With an introduction by Horst Oertel. Twenty-nine full page plates and 6 text illustrations. New York: Paul B. Hoeber.

The Glands Regulating Personality. A study of the glands of internal secretion in relation to the types of human nature. By Louis Berman, M. D. New York: Macmillan Company. 1921.

Medical Clinics of North America. Volume V, Number 3 (November, 1921). Philadelphia Number. Published bi-monthly (six numbers a year), by W. B. Saunders Company, West Washington Square, Philadelphia. Price per year, $12.

Pathogenic Micro-organisms, a Practical Manual for Students, Physicians and Health Officers. By W. H. Park and A. W. Williams, assisted by C. Krumwiede, Jr. Seventh edition. Philadelphia and New York: Lea & Febiger. 1920. Price, $6.

The seventh edition of Pathogenic Micro-organisms, by Park and Williams, assisted by Krumwiede, maintains the high standard of previous editions as a book of reference and contains much of the more recent advances in laboratory technic and diagnosis.

The Surgical Clinics of North America (Issued serially, one number every other month), Volume I, Number 6 (The New York Number) 295 pages, including complete Index to Volume I and 122 illustrations. Per clinic year (February, 1921, to December, 1921). Paper, $12 net; Cloth, $16 net. Philadelphia and London: W. B. Saunders Company.

The Medical Clinics of North America, Volume V, Number 3 (The Philadelphia Number, November, 1921). Octavo of 362 pages, 44 illustrations. Philadelphia and London: W. B. Saunders Company, 1921. Published bi-monthly. Price per clinic year: Paper, $12; cloth, $16.

BOOK REVIEW

Operative Gynecology. By Harry Sturgeon Crossen. 699 pages, 834 illustrations. St. Louis: C. V. Mosby Company. 1920.

This book, already well known to those interested in this field of surgery, now appears in its second edition, enlarged and revised. Few, even those conversant with the literature of the subject, have probably realized the number and variety of operative processes suggested for gynecological conditions until they looked over a work like the present one, which speaks not only for the industry of the author, but likewise for his sagacity and broad grasp of this field of surgery. We know of no other work of such magnitude. It is both a work of reference and a handbook of practice.

Operative procedures have been carefully classified in relation to the anatomical structures involved; this is especially true of those for prolapse of the uterus and bladder, and retrodisplacement of the uterus. Particular attention has also been given to the consideration of the choice of operative procedures with reference to the pathological condition present; this is one of the most noteworthy and commendable features of the work. Detailed analysis of the merits of operative procedures has been fully developed; their indications and limitations carefully explained; and the technical steps fully described. The range of subjects covered in this volume includes about the whole province of operative gynecology, including chapters on certain fundamental disturbances, postoperative handling, and medico-legal questions. The book abounds with numerous good and well selected illustrations, very clearly illustrating the various steps in the various operations.

A. J. L.

Tuberculosis and How to Combat It. By F. M. Pottenger. 273 pages. St. Louis: Mosby Company. 1921.

The above book is a very comprehensive presentation of the whole subject of tuberculosis from the patient's point of view. It answers in understandable language the numerous questions which the patient is constantly asking his medical adviser. The author devotes several chapters to the incidence and etiology of tuberculosis and then explains to the patient the various symptoms and method of treatment. He lays particular stress upon the necessity of a rational co-operation between patient and doctor if results are to be obtained, explaining the pathology of the disease and the reasons for methods advised in language which convinces but does not frighten the patient. The author's views on marriage of tuberculous patients are commendable because, "No matter whether they should or should not, some of them will." He, therefore, proceeds to explain under what conditions a tuberculous patient may marry, the disadvantage, but in certain cases the advantage.

Pottenger's book is one of the best popular versions of tuberculosis of the many already published and may be recommended to all patients afflicted with this disease. At the same time, the medical man will find its perusal very much worth his while.

W. C. V.

Principles of Medical Treatment. By Geo. Cheever Shattuck. 5th ed. Boston: W. M. Leonard. 1921.

It is a pleasure to note the appearance of this common sense volume. One is usually prepared to find a book of this sort resembling most others on the same subject. Ordinarily, they are of a type and consist mostly of therapeutic orthodoxy. This one, however, differs, and is a satisfactory compendium brought very thoroughly up to date. Naturally, in a volume of this size, the subject matter must of necessity be more sketchy and suggestive than complete in its discussions. Nevertheless the most important facts are all there in brief form, and the author is to be congratulated on having completed a difficult task. The chapter on medication boils down in comparatively few pages the really useful drugs in medicine, and is of really more service to the practicing physician than a pharmacopoea.

H. I. W.

DEATHS

Beebe, Charles E. Died in Woodland, Calif., December 20, 1921. Was a graduate of Vanderbilt University, Tenn., 1885; also Willamette Univ., Oregon. Licensed in California, 1889. Was a member of the Medical Society State of California.

Griffin, Jesse Ansley. Died in Huntington Beach, Calif., December 16, 1921. Was a graduate of the Baltimore Medical College, Md., 1906. Licensed in California, 1921.

Hawkes, W. J. Died in Los Angeles, December 29, 1921. Was a graduate of Hahnemann Medical College, Pa., 1867. Licensed in California, 1898.

Keating, John J. Died in San Francisco, October 31, 1921. Was a graduate of the Barnes Medical College, St. Louis, Mo., 1901. Licensed in California, 1901.

Nicholson, A. R. Died in Fresno, Calif., December 24, 1921. Was a graduate of University of Michigan, 1879. Licensed in California, 1895. Was a member of the Medical Society State of California.

Shuey, Sarah I. Died in Oakland, November 23, 1921. Was a graduate of University of California, 1878. Licensed in California, 1879. Was a member of the Medical Society State of California.

Thorwick, Martha G. (di Giannini). Died in San Francisco, November 16, 1921. Was a graduate of the College of Physicians and Surgeons, Chicago, Ill. Licensed in California, 1901.

Wright, Henry Eugene. Died in Sacramento, Calif., November 25, 1921. Was a graduate of the University of California, 1894. Licensed in California, 1894.

Dr. Annie L. Miller died on December 29, 1921, at her home in Oakland. Dr. Miller was ninety-four years old. She graduated from the Homeopathic Medical College of Cleveland, Ohio, February 26, 1869, and was licensed in California on October 19, 1882. She was a member of the Alameda County Medical Society and the California State Society.

Boone, Reunette E. Died in Santa Rosa, Calif., December 11, 1921. Was a graduate from the Medical College, Syracuse University, New York, 1881. Licensed in California, 1895, and 76 years old.

Bray, Nicholas. Died November 22, 1921, in Glendale, Cal. Was a graduate of State University, Iowa, 1885. Licensed in California, October, 1920. Age 66.

McSwegan, Daniel. Died in San Diego, December 2, 1921. Was a graduate of the Medical College of the Pacific, Calif., 1878. Licensed in California, 1878.

Streichan, Paul Herman. Died in Honolulu, T. H., recently. Age 34. Was a graduate of Stanford University Medical School, San Francisco, 1920. Licensed in California, August, 1920.

ORIGINAL ARTICLES

TREATMENT OF THE LACERATED AND INFECTED CERVIX UTERI.*

By ALBERT V. PETTIT, M. D., San Francisco, Cal.
From the Division of Obstetrics and Gynecology, Stanford University School of Medicine, San Francisco, California.

Interest in the results following the various methods of treating infected and lacerated cervices has been stimulated largely by the work of Leonard in 1914, in his comparison of the end results in amputation and trachelorrhaphy; and further by the article of Sturmdorff in 1916, on "Tracheloplastic Methods and Results."

This report is undertaken with the idea of estimating the relative value in the treatment of infections and lacerations of the cervix in three types of operations, namely:

Actual cauterization.
Trachelorrhaphy.
Amputation.

The investigation has covered 373 cases operated upon at the Women's Clinic of the Stanford University Medical School during the past eight years. Special attention has been paid to the relief of leucorrhoea, pelvic pain, objective cure of cervical pathology and the relationship to future pregnancies.

Infection of the lower genital tract in women is limited almost entirely to the glandular structures; vulvo-vaginal, urethral and cervical. These structures when intact are immune to practically all organisms except that of gonorrhoea. Infections of the undamaged cervix is practically always gonorrhoeal at its inception. The gonococci are replaced after variable lengths of time by other organisms, the gonococci seeming to serve largely to prepare the field for other types of infection. Curtis, in 1914, showed that these secondarily infecting organisms were various strains of bacilli, diplococci and streptococci, mostly anaerobic. In the damaged cervix the soil is prepared for infection by the opening up and traumatizing of the tissues. The importance of laceration of the cervix in the incidence of its infection is indicated by the fact that in 111 cases of laceration in this series, in which a microscopical section of the cervix was examined, 66 cases or 59½ per cent, were infected.

Infection of the cervix uteri concerns the racemose glands lining the cervical canal from the external to the internal os. Microscopical examination of sections through an infected cervix shows hyperplasia in the interstitial tissue about the glands, round cell infiltration, with occasional collections resembling actual abscess formation. If the cervicitis is at all chronic there are many cysts of the glands filled with mucoid material caused by the occlusion of the gland ducts. The so-called erosions are often present, in which the columnar epithelium of the canal has replaced varying amounts of the stratified squamous epithelium of the vaginal portion of the cervix. Infection of the cervical tissues diminishes in intensity as the internal os is approached and only rarely passes this barrier, to invade the endometrium. The immunity of the endometrium is well shown in 86 cases in this series which showed microscopical evidence of cervicitis, and in which specimens of endometrium were obtained at the time of operation. Of these cases, only 12, that is 14 per cent, shows any infection of the endometrium. It is also interesting to note that of these 86 cases, 37 per cent had palpable evidence of marked pelvic inflammatory disease, showing that the usual route of infection of the internal pelvic organs is not the uterine cavity.

Lymphatic drainage from the entire mucous surface of the cervix and uterus is upward and outward throughout the musculature of the entire organ towards the serous coat. Vessels leave the uterus by way of the sacrouterine, cardinal and broad ligaments. Many fine lymph vessels traverse these structures to empty into the sacral, hypogastric and lumbar nodes. By this path, infection of the glandular elements of the cervix spreads upward and thus may involve any or all of the internal pelvic organs. This is the usual route of infection in the production of the so-called pelvic inflammatory disease.

Symptoms of laceration and infection of the cervix as generally given are numerous and varied, but aside from the objective signs of discharge and the local irritation therefrom, practically all the complaints are due to the involvement of the pelvic organs by the upward extension of infection.

There is no treatment indicated for any healed laceration of the cervix in the absence of infection. However, from the known high incidence of infection of lacerations (59½ per cent), considerable can be done in the way of prophylaxis, that is, repair of the laceration at or near the time of its inception, before infection has taken place. There has been considerable discussion as to the correct time in which to repair lacerations of

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

the cervix; whether it should be done immediately following delivery or at some time during the first six weeks post-partum. Certainly the longer the interval between occurrence and repair of the laceration, the greater the possibility of infection. It has been urged that the benefits of immediate trachelorrhaphy are outweighed by the following disadvantages:

1. Added danger of the puerperal sepsis.
2. Odema of the tissues preventing proper coaptation of parts.
3. Free drainage of lochia prevented.
4. That the technique is difficult.

In our experience we have found none of these objections valid. In the routine exposure of the cervix after expression of the placenta in 700 consecutive cases in the Maternity Ward of the Stanford University Medical School it was found necessary to suture the cervix in 73 cases, roughly 10 per cent.

The maternal morbidity has not increased as a result of this procedure. Odema of the tissues of the cervix certainly obscures the anatomy somewhat, but the difficulty of getting proper coaptation of the lacerated edges is by no means insurmountable. After proper approximation of lacerated edges there should be no more obstruction to the drainage of lochia than in the unlacerated cases.

The technique is quite simple: Immediately after the expression of the placenta, the patient is put in lithotomy position. The cervix is exposed by making pressure over the fundus, and an assistant retracts the vulvar orifice, the edges of the cervix are grasped with ring forceps and the edge followed around, using three pairs of forceps. The lacerated edges are brought into vivid relief by the use of ether sponges. Lacerated edges are approximated with interrupted or continuous mattress chromic sutures. With obstetrical operations considered as major surgery, as they should be, the cervical manipulation in an immediate repair should not increase the liability to puerperal sepsis in any greater degree than the application of blades in a low forceps maneuver or the introduction of a vaginal pack.

Our results have borne out this statement, and it is seen that the 7 per cent morbidity is easily within the usual fever limits. The healing was more satisfactory in primipara than in multipara. Scar tissue from the secondary healing of old lacerations and the consequent higher percentage of cervical infection in multipara is the apparent explanation. The number of days required in the hospital was not increased, as it is our custom to keep patients in the hospital from 11 to 14 days post-partum. The factors in the production of lacerations will not be discussed, but it is important to note that lacerations occur in many spontaneous deliveries.

Immediate repair of laceration of the cervix following childbirth can only be done in a hospital and with an assistant, but the advantage to the patient's future welfare are easily worth the trouble when from 70 to 90 per cent of patients are saved the liability to infection of the cervix with its not infrequent sequelae.

End Results in Cauterization, Trachelorrhaphy, Amputation.

In the comparison of the end results in these types of cervical operation for the cure of cervicitis, with or without laceration, the records are compiled from 300 post-operative histories. The patients were all operated upon in the Women's Clinic and Gynecological Division of the Stanford University Medical School during the past eight years. The three series of 100 each were taken consecutively. Data concerning relief of cervical discharge, pelvic pain and subsequent pregnancies was obtained from the post-operative histories. The reports on postoperative cervical discharge are based on actual observations taken in the Women's Clinic. The general scheme for the investigation is that used by Leonard in 1914.

In the 100 cases of cauterization, 86 were cauterized radially, with the Paquelin cautery, under general anaesthesia; at each stroke of the cautery the point being buried in the cervical glandular tissue. Fourteen cases were done with the electric cautery without anaesthesia and were consequently more superficial. It is our custom to have the patient take a hot douche every day for a period of about two weeks following cautery, less frequently after that until at the end of about six weeks the cervix should be healed and clean. In the 100 cases of cauterization reported, an abnormal cervical discharge was present in 100 per cent. Gonorrhoea was suggestive in 18 per cent and positive in 7 per cent of cases. Pelvic inflammatory disease of the adnexa was present in 37 per cent of cases.

In the 200 cases of trachelorrhaphy and amputation, 125 complained of leucorrhoea and there was microscopical evidence of cervical infection in 132 cases. Erosions were present in 120 and lacerations in 162 cases. In general, trachelorrhaphies were done on those with a relatively mild cervicitis, while those of more extensive infection of laceration were amputated. Two types of trachelorrhaphy were done, 87 Emmett type and 13 Sturmdorff. In the amputations, 51 were of the circular type and 49 the Shroder operation.

The effects of cauterization, trachelorrhapy and amputation were contrasted in the relief of leucorrhoea in 225 cases. The cure of the discharge by amputation in 82 per cent is in marked contrast to the 62 per cent cure in cauterization and the 40 per cent cure in trachelorrhapy. Cauterization shows a high percentage of cases merely improved; this is probably because of an insufficient cauterization. In the cured or improved totals, cauterization leads, with trachelorrhapy only 59 per cent.

A comparison of the two types of trachelorrhapy shows the Sturmdorff operation leading the Emmett operation in the cure or improvement of leucorrhoea, 87 per cent to 57 per cent. The inference is plain; cure of cervical discharge lies in the removal of the infected glandular tissue to the cervix. The results of the Sturmdorff

enucleation compare favorably with those of amputation.

The relationship of pelvic pain and dysmenorrhoea to cervical disease is not always clear, on account of the not infrequent association of inflammatory and postural pelvic pathology. Of 89 patients complaining of pelvic pain or dysmenorrhoea, 43 were cauterized, 28 had trachelorraphy and 18 had amputation performed.

The cases have been divided into two groups, those having only cervical and possibly perineal work, and those having a laparotomy in addition to the cervical operation. Although the number of cases is small, the percentage is still against trachelorraphy, with cauterization showing 86 per cent cured or improved, amputation 80 per cent and trachelorrhaphy 60 per cent. The explanation is not far to seek: trachelorrhaphy fails to remove the infected tissue and symptoms from cervical lesions lie mainly in the infection present.

A series containing 199 cases was compiled which represents those of the original 300 who were below the age of 40 at the time of their operation and who were not surgically sterilized at that time. The incidence of pregnancy following trachelorrhaphy and amputation is practically the same, 22 per cent and 21.5 per cent, respectively. This is rather interesting in the light of Leonard's conclusions, that pregnancies were about twice as frequent after trachelorrhaphy. It must be remembered that amputations are performed at various heights, and that the functions of the uterus as regards pregnancy is disturbed in proportion to the amount of muscular tissue removed. In this clinic we have always removed as little tissue at operation as was compatible with removal of the infection. The cauterizations show a remarkably low percentage post-operative pregnancies, 9 per cent. Part of the explanation probably concerns the fact that the incidence of pelvic inflammatory disease was about twice that of the other two series. There were no cases of post-operative stenosis as indicated by the development of dysmenorrhoea to explain the sterility. It is seen that the number of cases which showed merely a diminution in the amount of discharge was very high, 34 per cent. After cautery we know that the cervical canal is diminished in caliber so that if the cervical discharge is not cured, it may still be sufficient to plug the os. It is known that stenosis is not a frequent cause of sterility but that the presence of a mucous plug in the canal is an efficient barrier to the ingress of spermatozoa. From this consideration we can say that pregnancy following cauterization of the cervix is infrequent and that the incident following trachelorrhapy and amputation is about equal.

The course of the pregnancies are considered after cervical operations. The question of the spontaneous interruptions in pregnancies and the character of labor in those progressing to term is of considerable importance in determining the value of cervical operations for women in the childbearing period. The average age in these cases was 29½, the average age in the three types of cases are close enough to eliminate that as a factor in the comparison. In this chart the number and character of pregnancies before and after operation are contrasted. It is seen that after cauterization, the number of pregnancies going to term is larger than before operation, with a consequent decrease in the number of abortions. In the cases of trachelorrhaphy and amputation, there was a very slight increase in the tendency to abortion, the increase being about equal in the two types of operation. Labor following these operations shows no marked departure from the normal. After cautery all the cases that went to term had apparently normal, spontaneous labors. Of the twelve cases of trachelorrhaphy who went to term, nine had easy, spontaneous labors, one was delivered by abdominal section on account of a previous repair for complete perineal laceration and two had labor induced with Vorhees' bags, because of failure to go into labor due to rigidity of the cervix. In the cases of amputation, eight became pregnant, of which two aborted in the second month, one had premature rupture of the membranes with prolapse of the cord in the fourth month, this being a case in which a high amputation had been done. Of the five cases progressing to term, four had easy, spontaneous labors, while the fifth went into labor a month past term, had a moderately long labor and received a laceration of the cervix.

In every case of Emmett trachelorrhaphy the cervix was re-lacerated at delivery.

In a consideration of the results following operations on the cervix it becomes evident that the pathology and symptomatology depend upon the infection in the cervical glands. The relief of symptoms is most marked in those procedures which destroy or remove the infected tissue. Excision of the infected area, as in amputation, has given the best result in the cure of symptoms and has had practically no more deleterous effect upon pregnancy than other operations. Cauterization has given a high percentage in the cure of symptoms, but the incidence of pregnancy after it is very low.

The operation which combines the virtues of amputation with the least apparent disturbance of the function of pregnancy is that described by Sturmdorff. We perform the operation essentially as described by him, with the exception of a few minor details, such as the use of chromic catgut suture material in place of the silkworm gut advocated by Sturmdorff, and the use of a buried suture on either side of the amputated cervix to control hemorrhage. The operation as performed in this clinic is as follows:

Slight preliminary dilatation of the cervix with bougie dilators. This need cause no damage if done carefully and facilitates exact dissection of the glandular tissue to the internal os and permits good approximation of the inverted vaginal flap to the endometrial margin. With the anterior and posterior cervical lips in the grasp of tenacula, a circular incision is made around the cervix at

the juncture of the infected cervical and healthy vaginal mucosa. The vaginal cuff is then well loosened with dissecting scissors all the way around the cervix in order to give good mucosal flaps for inverting. If there is marked cystocele, care must be taken to separate and push up the lower bladder margin. With tension on the cervical lips, the gland-bearing area is dissected out with a sharp knife, to the level of the internal os. When about half this cone is enucleated, retraction is made laterally on the vaginal flaps and a buried suture is laid on each side in the muscular tissue of the cervix at right angles to the long axis of the organ. The operation is practically bloodless from this time on and we believe the tendency to post-operative hemorrhage is diminished. After the cone of glandular tissue has been amputatd at the height of the internal os, the anterior and posterior vaginal flaps are inverted into the hollowed out cervix by the double inverting stitch of Sturmdorff. Thus, healthy vaginal mucosa is substituted for infected cervical mucosa and the musculature and the nerve supply of the uterus are undamaged by the operation. If necessary, a figure-of-eight approximating suture may be used in the mucosa on either side of the new external os. Thus six sutures are used in all. The technique is simple, and the operation can be performed in the majority of cases in 10 to 15 minutes, with no special instruments.

CONCLUSIONS.

In hospital obstetrical practice, in trained hands, the best prophylactic procedure against the development of infection of the cervix is the routine exposure of the cervix in primipara, after delivery, and suture of the lacerations.

For the cure of infection and laceration of the cervix, with the accompanying symptoms, certain types of amputation are the operations of choice.

Trachelorrhaphy is preferable to cauterization if future pregnancy is a consideration.

Cauterization, for the treatment of infection of the cervix, should only be undertaken if future pregnancy is no longer a consideration.

The Sturmdorff conical enucleation of the glandular elements of the cervix possesses the virtue of high amputation, and should give the least possible interference with future pregnancies.

NEW YORK WELFARE AGENCIES UNITE

A news item states that efforts are under way to group, for purposes of co-operation, more than two thousand charitable and welfare organizations of New York. It is reported that "charitable societies, with their increasing specialization and their undeniable duplication of effort, have been subject of late to a considerable amount of criticism from persons who fail to see a reason for their multiplicity."

What a commentary! The reasons ought to be perfectly obvious, but they are not reasons that mean efficient medical and social service for the public.

PRELIMINARY REPORT ON AN INVESTIGATION OF THE "PROVOCATIVE WASSERMANN" CONTROLLED BY THE ICE-BOX METHOD

By RUTH THYGESON SHEPARDSON, A. B., Special Worker, Skin Clinic, Stanford University Medical School

In view of the uncertainty regarding the status of the "provocative Wassermann" test, it was decided to try out the method with the aid of funds from the United States Interdepartmental Social Hygiene Board. This work is being carried on in the service of Professor H. E. Alderson (Skin and Syphilis Clinic) of the Stanford University Medical School. Owing to unforeseen interruptions, the preliminary report has been much delayed. Although recent publications have described and discussed the ice-box method, much of our work antedates the same, having been conducted in 1919-1920.

The "provocative Wassermann" appears still to be in the indefinite stage of experimentation where the opinions as to its value in the diagnosis of syphilis vary anywhere from enthusiastic advocacy to unqualified disapproval.

It was Gennerich in 1910, who first called attention to the phenomenon of a reversal from negative to positive in a Wassermann reaction soon after an injection of salvarsan. He reported twelve cases, each exhibiting one negative before the injection, and becoming positive from twenty-four hours to fifteen days (the major portion within the first three days) after the injection. This observation of Gennerich was soon confirmed by Milian.

In 1914 we read of some experimentation on the subject by Pease. He believed the "provocative" analogous to the Herxheimer reaction, namely the accentuation of the clinical symptoms of syphilis immediately following treatment with salvarsan, and thought that the most reasonable explanation of the "provocative" effect was that more spirochetes were killed just after the injection and, therefore, more bodies thrown into the blood. In his tests he used 0.4-0.6 gms. of neosalvarsan, took the patient's blood immediately before and on several days following the injection, and observed that the reaction was most apt to become positive on the two days following the injection. His conclusions were that the "provocative Wassermann" was valuable in all stages of syphilis, but chiefly in the tertiary stage, and that it was "fully as reliable as the Luetin test" and offered "the best evidence at present of actual cure of lues."

In direct opposition to these favorable observations of Pease, is King's report in 1916. He gets the impression from the literature that the test is by no means on an established basis, and calls attention to the work of Boas and Haller on the factors of technical error and variation in the reagents used in performing any Wassermann test. Boas showed different results with the same serum, same technic, and same reagents at different times. Haller, however, did not discover any appreciable variation in the serum itself, con-

trary to Craig's statement in 1914 that "great variations may occur in the complement-binding power in the sera of untreated syphilis." King observes that in addition to these factors which might influence the result of the Wassermann test, is the fact that the Wassermann test per se is not sufficiently standardized, objections which all those disclaiming the "provocative" strongly emphasize. King, himself, performed "provocatives" in sixteen cases, and in only one was there any provocative effect, and that appeared one hour after the injection of salvarsan. So his conclusion is that "definite proof of the existence of the 'provocative Wassermann' following salvarsan is not at hand at the present time."

In 1917 we read two opposing reports on the "provocative," the first by Stokes and O'Leary, and the second by Craig.

Stokes and O'Leary ran a series on 103 tests. We shall go into a little more detail as to their results, since we have classified our own results more or less along these lines. Their technique was in brief as follows: An injection of 0.3-0.4 gm. salvarsan, a Wassermann test within one week before the injection, blood drawn from each patient on the third, fourth and seventh day after the injection. Three antigens were used, namely, acetone insoluble, alcoholic extract of syphilitic liver, and cholesterinized alcoholic antigen. Of their 103 tests, 18.4 per cent came out definitely positive with the cholesterinized antigen. Of these 26.3 per cent showed no objective clinical signs suggesting syphilis, 73.7 per cent showed suspicious signs, 57.8 per cent showed clear histories of primary and secondary manifestations, 31.5 per cent suspicious histories, and 10.7 per cent no histories. Sixty per cent of the 103, on receiving the therapeutic test, clinched the diagnosis. Of the 81.6 per cent of the 103 cases showing no reversal, 67.8 per cent were clinically suspicious and 65.2 per cent, on receiving active treatment (therapeutic test), showed improvement impressive enough to establish the diagnosis. Their conclusion was that the therapeutic test (60 per cent as opposed to 18 per cent) is of more value than the "provocative," and that if no good clinical ground for suspecting syphilis exists, the percentage of positives in the "provocative" is so small as not to justify the procedure. They ran another series of tests on the "provocative" in 1920 by a modified Noguchi method and obtained 8 per cent positives as opposed to the old 18 per cent, but still held that the provocative was a necessary procedure in a complete and thorough examination for syphilis.

Craig is one of the advocates of the "provocative Wassermann." He recommends this procedure after the reaction has remained negative for at least a year without treatment, and in case this is negative, a spinal fluid examination. He found that a "negative" became "positive" within a few hours to five to six days after the injection, and that his percentage of positive "provocative" effects ran about 20 per cent. He accounts for the reaction on the basis either of more spirachetes killed or greater activity on the part of these organisms after the salvarsan. His opinion is that it is a valuable aid to the diagnosis of cure and the diagnosis of the existence of the disease, and he has used it extensively with good results especially for the latter purpose.

A later article in the literature on the "provocative" is that of Pollitzer. His conclusions are: "(1) The Wassermann test is so subject to errors of various kinds that dependence on a single positive reaction in a series of tests, is not justified. (2) In an uncured case a change from negative to positive may happen to coincide with the provocative injection, and a positive after the injection may be the result of the normal increase in reagent without relation to the injection. (3) In 150 treated cases I found not a single case of "provoked" reaction, while the assumption of a cure in all these is obviously untenable. (4) In a series of temporarily negative cases selected as probably not cured, the provocative test failed to indicate the presence of syphilis not cured. (5) The 'provocative' is a useless and often misleading procedure."

One of the latest reports is that by Strickler, Munson, and Sidlick, in 1920. They gave intravenous arsphenamine to thirty non-syphilitic patients who had a negative Wassermann reaction, a negative syphilitic history and skin lesions definitely non-syphilitic. Following the injection 16, or 66 per cent, gave at least one positive Wassermann; 14, or 58 per cent, gave two or more positive reactions, and 9, or 38 per cent, gave reactions of 2 plus or greater intensity. This would tend to show that perhaps a positive reaction was the product of the arsphenamine.

R. A. Kilduffe, in 1921, injected rabbits intravenously with weekly doses of arsphenamine, neo-arsphenamine, and mercuric chloride, closely approximating in rabbits the conditions in the investigations of Strickler, Munson, and Sidlick on humans. The results were uniformly negative, a positive Wassermann not being produced in any animal in any series.

In our work the technique employed was that used in the Lane Hospital Wassermann Laboratory supervised by Miss Beatrice Howitt. One-half cc. each of guinea pig complement, antigen and normal salt solution plus 1/10 cc. of inactivated patient's serum were incubated one hour at 37.5° C. in the water bath, then taken out and 0.5 cc. each of goat's corpuscles and amboceptor added, and put back into the water bath until hemolysis took place in the proper control tubes. A parallel series had their primary incubation (that is to say, before the hemolytic system was added) in the *ice-box at 4° C.* for four to five hours, and on adding the hemolytic system were then incubated in the water bath as was the other series. Three antigens were employed, cholesterinized beef heart, alcoholic guinea pig heart, and acetone insoluble.

This method of carrying on the tests enables us to get some interesting sidelights on the relative delicacy of the three antigens used, and also

on the *much greater delicacy of the primary ice-box* incubation as opposed to the primary water bath incubation method.

A few words on the subject of the ice-box method. The first one in this country to advocate its use was Archibald McNeil of the Department of Health Laboratories, New York, in 1912-13. He stated that by a four-hour primary incubation in the ice-box there could be obtained 10.3 per cent more positive reactions than by the usual one-hour incubation at 37½° C. Since then repeated investigations on the subject have been made throughout the country. Practically every one has found that the primary ice-box incubation is the more sensitive. Smith and MacNeal (W. J.), in 1916-17, recommended as very satisfactory the simple alcoholic antigen with a four to twenty-four hour primary ice-box incubation at 8° C. They said that though cholesterinized antigen was more sensitive, it was apt to yield false positives. Berghausen, in 1919, reported that the ice-box method was found by experiment to be so satisfactory that it was adopted at the Cincinnati General Hospital. He stated that there was no evidence of false positives, and recommended the simple alcoholic antigen. Ward Burdick of Denver, in 1920, gives the following comparative statistics:

	Water bath.	Ice box.
Clinically non-luetic	100% negative.	100% negative.
Secondary untreated	100% positive.	100% positive.
Secondary treated		more positives.
Tertiary untreated	55% positives.	100% positives.
Tertiary treated		more positives.

J. A. Kolmer of Philadelphia, after four years' work on seventeen different methods of primary incubation, recommends the ice-box method as the best. He says four to sixteen hours at 8° C., followed by one hour secondary incubation in the water bath, gives admirable results. Rhamy at Fort Wayne, Indiana, in 1921, reports that the ice-box incubation is about 12.6 per cent more sensitive and therefore that much more accurate, and that doubtful positives by the primary water bath incubation method show up as positive by the primary ice-box incubation method.

We found that in the clinically luetic (our series consisting of 134 Wassermanns) the ice-box method yielded 56.6 per cent 3 plus positives as opposed to 32.2 per cent with the water bath method, with none by either method in the clinically non-luetic. We also ran another small series of 220 Wassermanns with the ice-box method on patients having histories *negative* for syphilis, *no clinical signs or symptoms* of the disease and a *negative* Wassermann by the water bath method, and had uniformly *negative* results, thus tending to prove that the ice-box method does not yield false positives. In our tests the cholesterinized antigen was the most sensitive, the simple alcoholic next, and the acetone insoluble the least.

Unfortunately, we were not able to use the ice-box series in computing the number of "provocative" effects, since the old Wassermanns taken before the injection of salvarsan were done only by the water bath method. Therefore, only the first ten cases of this series were considered positive. All of these ten had shown negative Wassermanns by the ice-box method before the provocative injection was given.

The Wassermann reaction before the injection was taken as part of the routine of the Skin clinic, and from one day to two months after taking the blood (the average being under one week) a "provocative" injection of 0.3 to 0.6 gms. arsphenamine was given. Then the blood was taken *every other day*, beginning either the first or second day after the injection, until seven tests were recorded.

	Treated or untreated.	No. of days Wass. negative before prov. inj.	History No. of patient.	Gms. of arsphenamine.	No. of days after inj. before Wass. became positive.	Water bath method.	Ice-box method.	Luetic history.	Clinical symptoms.

* Wass. before inj. negative by ice-box, so subsequent ice-box reading could be taken as reversal.

† Wass. negative 14 days before.

There were only *fifty-nine* cases in which we were able to obtain complete data. Of these, ten or 17 per cent showed a reversal from nega-

tive to positive (using the ice-box and water bath method before the injection and afterwards). This occurred in two to fifteen days (average, two to six days) after the injection of arsphenamine. This reversal had to be (in order to be counted) from 3 minus or 1 plus 2 minus to 2 plus 1 minus or 3 plus by the cholesterinized antigen, never from 3 minus to 1 plus 1 minus. The remaining 49 or 83 per cent remained negative throughout.

Of these 49 cases it will be noted that numbers 17, 20, 25, 26, 28, 32, 49, 54, and 56 became positive by the ice-box method, but were not considered "positive provocatives" because the test before the injection had been made by the water bath method only. All of these but two had positive luetic histories or clinical symptoms, or both, so the positive ice-box result is at least suggestive. Had these nine cases been classed as "positive provocatives," of course our percentage of reversals in the positive direction would have been much higher.

Of the ten (17 per cent) positives, 40 per cent had positive histories, 30 per cent had suspicious histories, 30 per cent had negative histories, and 60 per cent had positive clinical symptoms some time, 10 per cent had suspicious clinical symptoms, 30 per cent had negative symptoms.

Of the forty-nine (83 per cent) negatives 28 per cent had positive histories, 37 per cent had suspicious histories, 35 per cent had negative histories, and 25 per cent had positive clinical symptoms at some time, 33 per cent had suspicious clinical symptoms at some time, 42 per cent had negative clinical symptoms.

CONCLUSIONS

1. Our percentage of positives (17 per cent) is about the same as Craig's (20 per cent) and Stokes and O'Leary's (18 per cent). (The 18 per cent obtained by Stokes and O'Leary in 1920 was by the Noguchi method.)

2. A so-called "provocative reaction" does in all probability occur. However, we cannot be sure in the face of all the uncertainties of the Wassermann reaction, that this effect is not due to some imperfectly comprehended factor either in serum, reagents, or technique.

3. If a positive Wassermann does justify treatment, and in 17 per cent of cases this can be obtained by the "provocative" procedure, it might be worth while employing in private practice, but not in clinical practice, where the amount of time necessary for the patient to stay away from work is too great to justify any benefit the patient might receive thereby.

4. We believe that an equally valuable and less time consuming and laborious procedure is to have the patient return for repeated Wassermanns (*to be done by both ice-box and water bath methods*) at varying intervals depending upon the clinical indications and history.

OPERABILITY OF THE SENILE PROSTATE—A REMINDER TO THE GENERAL PRACTITIONER

By WIRT BRADLEY DAKIN, M. D., Los Angeles

It is the aim of this paper to act as a reminder to those who are too occupied with their professional duties to keep informed regarding senile prostate, or who have forgotten the recent favorable results of the management of this condition, or who have still to be convinced of its truth. It is depressing to the urologist and to the patient to have it said that the patient has a poor chance if operated, and palliative treatment is of uncertain benefit.

Many examples of the results of modern treatment of senile prostate could be given, but for brevity only two cases will be reported.

Case 135—Operated in two stages with a six weeks' interval, two years ago. Age 83. Widower. Teacher by occupation.

At the time of my first examination, this patient was semi-comatose with a complete retention and overflow. During two previous years he had had occasional attacks of retention and had been catheterized.

During the present attack an attempt had been made to keep a retaining catheter in, but the last time it came out the attending physician had been unable to replace it. I had catheterized this patient and had obtained 900 cc. of urine.

The early and usual symptoms of prostate enlargement began ten years previously. Rectal examination showed a very large prostate. No cystoscopy, blood pressure, or kidney functional tests were made. The patient was taken to the hospital at once for a cystotomy and was drained for six weeks before his kidney function or general strength would permit the second operation. It was a week after the first stage before he was clear mentally, and stated that he was unable to recall occurrences of the past two weeks. The second operation required less than fifteen minutes. The bladder wound healed in ten days and the abdominal in eighteen. The patient was up in a wheel chair in four days and walking in nine days. He urinated normally through the urethra on the fourteenth day when his urethral retaining catheter was removed and he has continued to do so ever since. His general health is excellent as shown by frequent walks of from two to five miles for exercise.

Case No. 140. This patient, because of acute retention, was taken to the hospital three years ago. The condition was relieved and although an operation was advised at once, no one would assure the family that the patient could be successfully operated upon, so he was returned home and continued catheterizations.

For two long years the patient's wife had to be a constant companion because he would not let anyone else catheterize him. In addition to having recently he had been totally deaf for thirty years, while all of his urinary trouble could have been avoided had correct information been more readily obtainable.

The remaining history of this case is similar to the first one mentioned. Since the operation the patient has been in excellent health and can be found in a near-by town working in his garden almost every day.

Both of the preceding cases were advised that they were too old, and their general health such that they could not stand any operative procedure.

The usual conditions considered as contra-indications to operative procedure are: Age; urosepsis; asthenia; cardio-vascular changes; possibility of urinary incontinence or impotency following the operation.

Age is no logical contra-indication. Culler collected data on patients, with an average age of sixty-seven years, that he had operated upon during a period of one and a half years. He believes that the average age of these patients suggests that senility may not be a bar to operative procedure as often as supposed, and that certain physical defects in old age are remediable without the high mortality rate anticipated by many. His experience with these old patients inclines him to conclude that aged people are often passed by who may be salvaged without more than ordinary surgical risks and that disaster in such cases is often born out of delay and compromise.

Careful pre-operative attention, reasonable speed in operating and painstaking after treatment will reduce risks which are derived from cardio-renal defects and other concomitants of age.

Anhedonia of senility probably eliminates those surgical risks common in younger patients which grow out of fear and anxiety; indeed, old men appear to face the issue of surgical operation with extraordinary calmness and fortitude and are docile patients during the post-operative period. Culler concludes that senility as a contra-indication to surgical operation is made applicable too generally.

Asthenia, urosepsis, and cardio-vascular changes may all be corrected by proper and sufficiently long pre-operative treatment and under good management these patients regain their strength, appetite, and general health to such an extent that not only the family but the patient remarks that it seems unnecessary to operate at all, because they feel as well as they did before their trouble began. I have had two patients who refused to proceed any further, but were compelled to return later because of recurrences of obstructive symptoms.

Urinary incontinence, except in occasional cases of malignancy, does not occur if patients are carefully operated upon. The family, patient, or physician may have known, however, of such instances and frequently ask for an explanation.

Patients not critically ill, or advanced in years, and not needing an immediate operation, very frequently inquire of the possibility of impotency as a result of operation. In a series of 150 cases I have endeavored to determine this question, and find that if impotency develops just previous to, and as a result of their urinary trouble, there is a partial return of sexual desire, and occasionally they are normal for that period in life. If there was partial or complete impotency previous to the onset of their urinary disturbance, the prostatectomy will have no direct bearing on the case.

Statistics concerning the average duration of life of cases of prostatic obstruction not subject to operation has been best presented by Squier. This author presents a table of thirty-four cases. Conclusions drawn from this series of cases reveal that:

Fifty per cent of unoperated patients die within three years from the onset of obstructive symptoms where catheter life is not necessary.

1. The beginning of catheter life shortens this expectation of life about 50 per cent.

2. Beginning of catheter life increases the mortality of 66⅔ per cent within the shortened period.

3. The average length of life of unoperated carcinomas is thirteen months from the onset of symptoms.

In an interesting article by Deaver rather recent statistics of cases of prostatic obstruction subject to operation are well presented.

"In 1905 Whiteside reported that the average mortality among many American prostatectomists was 20 per cent, with only 30 per cent of complete cures. A similar study was made in 1915 in which the work of thirty-five surgeons was recorded, giving data in 1423 cases. In this latter series about half of the surgeons submitting reports operated on considerably more than half of the 1423 cases. These are the men of wide experience and the mortality rate in their work is less than 3 per cent, in contrast to a mortality rate of 26 per cent, as reported by the less experienced operators.

"As regards post-operative mortality the percentage incidence has fallen from a general average of 70 per cent in 1905, to 18 per cent in 1915, while among the more experienced operators it was but 7 per cent, according to the more recent figures"

The same is true among the English surgeons. In the first series of 100 cases operated upon by Freyer, the mortality rate was 10 per cent; in his last cases it was only 3 per cent, with a general average among 1000 of 5.5 per cent. About the time when Freyer's mortality was slightly over 6 per cent (1908), C. M. Page collected statistics from the records of four London hospitals for the corresponding years and found the mortality rate to be 21.5 per cent. Wade reports a mortality rate of 35.4 per cent from one of the largest hospitals in Scotland for the same period, and states that during the year of 1906, sixty-nine patients were subjected to prostatectomy in St. Thomas' Hospital in London, of whom fourteen died, giving a mortality record of

20.3 per cent. These statistics are, however, the result of operations antidating the present knowledge of operative technique.

SUMMARY

At the present time, taking all cases as they come, including those patients that do not respond in the most satisfactory manner to prolonged preoperative treatment, the mortality ought not to be more than 2 to 5 per cent.

DIARRHOEA IN INFANTS IN RELATION TO CERTAIN FOOD INTOLERANCES.*

By H. H. YERINGTON, M. D., San Francisco, Cal.

During the past few years an immense amount of work has been done in this country on the nutritional diseases of childhood, and out of this work have come many valuable points on the treatment of intestinal disturbances. We are now able to classify many types of diarrhoea, and apply a rational form of treatment to each type.

Owing to our mild California climate, and good milk supply, the infectious or "summer diarrhoea" does not concern us as much as it does the men in our large Eastern cities. However, the disturbance caused by the intolerance in infants for certain foods is present here, and is the subject of this paper.

Food injury is classified by L. T. Royster under three headings:

(1) Acute, in which proper food is given, but the intestinal tract is overloaded.

(2) The accidental administration of an excess of one or more food elements in a bottle baby's formula (either fat, sugar or proteid). In these cases vomiting is more frequent than diarrhoea, fever is absent, and occasionally convultions occur.

(3) Food Injuries (chronic). A child with a beginning intolerance for one of the food elements will eventually acquire an intolerance for all others, if the elemental portion is not regulated in time. Giving an infant an amount of any one of the main food elements, as fat, sugar, or proteid, in excess over a long period of time will cause a diarrhoea which may become fatal. The character of the discharge depends on the food element in excess. A mixture too strong in milk, fed over a short period of time, is a frequent cause of diarrhoea.

The beginning diarrhoea of "Simple Indigestion" is caused by fermentation of carbohydrates and fats, in which saprophytic bacteria are the ones most active. Another type is the putrefactive one caused by the overfeeding of proteid. In both types the activity of the normal intestinal flora become very much altered.

A beginning food injury is often the fault of the physician in allowing the mother to take the responsibility of her infant's bottle feeding. She obtains her information from neighbors or from a feeding book, and the formula which has agreed with another baby may set up a chronic diarrhoea of a severe type in her own infant.

In order to prevent intestinal disorders in infants, we must be familiar with the percentages of foods, and know something of their caloric or food values. Most important of all, we must be able to do routine stool examinations and know something about modern pathology of the intestinal excretian.

Infants sufferings from a beginning food injury often show very characteristic symptoms. The patient who has been overfed with high fat mixtures or too much milk is fussy, cries continually, sleeps on his abdomen or on his arms and knees; the stools in this case are at first soft, buttery, contain soft white curds, and is often called the "scrambled egg" stool. When the case becomes more chronic the stool becomes hard, crumbly and is of a grayish color. The fat in the latter stool is in combination with calcium and magnesium and are typical "soap stools." When the excess of fat becomes greater, a relative acidosis results, with an excess of ammonia in the urine. There is then a diarrhœa with very frequent, watery, acid stools.

Indigestion from carbohydrates is produced by an excessive amount of sugar or starch in the food, and the characteristic symptoms are vomiting, flatulence and colic. These babies are very uncomfortable, the buttox is raw and irritated with acid stools. The passages are loose, green in color, very acid in reaction and show marked evidence of fermentation. The microscopic examination is important. The fat globules show red when stained with acetic acid Soudan iii, and the starch grains blue with Lugol's Solution. Both the fat and carbohydrate stools are acid and the protein stool alkaline in reaction.

The protein type of indigestion is much more frequent in the breast than in the bottle-fed baby and is usually easily corrected.

The symptoms from an excess of casein are vomiting of large tough curds, flatulence, and somnolence. The stools are liquid, brown in color, with a putrefactive odor, and contain large bean-like curds. A point in the differential diagnosis between a fat and proteid curd is that the former will dissolve in ether and the latter will not.

We now come to the extreme type of food injury or extreme malnutrition, with marked diarrhœa, which is so resistant to treatment. These cases are the ones having an intolerance for all food.

The characteristic thing about these babies is the extreme degree of dehydration they present. The loss of weight is rapid, there is no subcutaneous fat and the bones appear prominent through the dried-out skin. The eyes are sunken and the fontanel depressed. The skin is gray and pallid and lacks elasticity. The respiration is deep, and the pulse soft and rapid. The rectal temperature at times reaches 103° or 104° F. The child is very apathetic, crying at times, then lapsing into a semi-comatose condition. The liver and spleen are usually palpable and the abdomen scaphoid. Very little urine is passed and it contains small amounts of albumen.

* From the Sub-division of Pediatrics, Medical Department of Stanford University. Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, San Diego, May, 1921.

Infants are in a critical condition, and unless careful treatment is instituted, death will result within a few hours' time.

In discussing these cases, Marriott has observed that there is a marked acidosis present; due to a decreased volume flow of blood, which leads to an accumulation of acid products of metabolism in the tissues and a decreased alkaline reserve of the blood. If the volume flow of blood is diminished in the abdominal vessels, the functional ability of the gastro-intestinal tract to care for food is impaired, and if normal amounts of food are given diarrhœa results.

Fever is produced by the decreased amount of water in the body available for evaporation, and water evaporation is of great importance in the heat regulation of the infant's body. Fever, as a result of dehydration, has been frequently seen in infants, adults, and animals, and examples are seen in the starvation temperature of new-born infants.

If an infant suffering from diarrhœa is given food, especially sugars or fats, the diarrhœa in the majority of cases becomes worse, and the degree of anhydremia tends to become greater.

It is imperative, then, in these cases to get fluid into the system, and as these babies cannot take enough water by mouth to be of any benefit, other methods must be employed. Howland considers the injecting of Ringer's Solution into the peritonial cavity the most efficient means of accomplishing this. Another valuable method is the intravenous injection of a glucose solution. The latter is found useful because the carbohydrate spares the protein destruction going on in the body. Added fluid may be given by mouth in small quantities and by subcutaneous injections.

The next thing to do is to get food which can be used immediately and one which the baby can tolerate. As the majority of these infants are suffering from intolerance of both fat and carbohydrate, the ideal food would be one high in proteid, which would change the intestinal flora from a fermentative acid state to a putrefactive alkaline state. Eiweissmilch, protein or albumen milk, fills this requirement, being high in proteid, low in carbohydrates and fats, and has a relative high food value. This preparation is made by separating the whey from the curd, breaking the curd up into fine particles by putting it through a sieve and then adding buttermilk to the mixture. This gives us a mixture containing:

Fat	2.5%
Sugar	1.5%
Protein	3.0%
Salts	0.5%

The preparation can be made fat free by using a fat-free milk. Certain manufacturers put out products, such as "Larasan," which are much simpler to make up and produce the same beneficial results.

In closing this paper, I would like to describe two cases which illustrate the remarks I have made, and bring to your attention the practical treatment of such cases.

Baby M., age 9 months, weight 9 lbs. 8 oz., admitted to hospital June 28, 1920. Discharged July 15. This baby was three weeks premature, doing well on the breast for two months, then up to the fifth month did poorly on artificial foods, especially high fats; then it had influenza, from which it recovered. Since then the baby has been on Eskay's Condensed Milk, top milk mixtures, and lately fresh undiluted goats' milk. For the past two weeks there has been vomiting, diarrhœa, curdy, acid, fat-type stools, with a loss of two pounds in weight.

Physical Examination—Shows a very thin, marasmic-type baby, skin dry, hanging loosely on the body, abdomen distended, tympanitic, liver enlarged, spleen palpable. The extremities are thin, cold, musculature poor. The baby has the appearance of being very much dehydrated.

The child is having frequent, watery, frothy, acid stools. The buttox is excoreated. It regurgitates all food given to it and at present refuses to take its bottle. The pulse is rapid and of low tension. Temperature ranges between 98° and 103° F. and the child is restless and uncomfortable, crying when disturbed.

Hospital Record—On admission the baby was put in a warm bed, flushed out, and given a weak milk, dextro-maltrose, barley water mixture by mouth. What little was taken of this was regurgitated, and an attempt was then made to give the baby a soda solution after the stomach had been washed out. The frequent movements continued and the patient was very restless and uncomfortable during the day.

At 6 p. m. pulse was more rapid, temperature 103.8° F., restlessness more marked, bowels still very loose, and the child looked as if it would die before morning.

At 7 p. m. an intraperitoneal injection of 350 cc. of normal saline was given, followed immediately by an intravenous injection, via the superior longitudinal sinus, of 50 cc. of a 5% solution of glucose. The child had a much more comfortable night, and at 8 in the morning 400 cc. of normal saline was again injected into the peritoneal cavity, followed by 50 cc. of 5% lucose by vein. Following these injections the temperature dropped from 103.2° to 100.6° F., the child slept and the pulse become stronger and slower. At 12 m. the following formula was given:

Fat-Free Protein Milk	24 ounces
Dextro-Maltrose	1 tablespoonful
Barley Water	8 ounces

Six ounces to be given every four hours and five feedings in twenty-four hours.

During the next twenty-four hours the stomach was washed with plain water before each feeding, and the feeding then given by tube. At the end of twenty-four hours the baby had regained a pound of its weight and the improvement in its general condition was marked. The baby went home in three weeks on a whole milk formula, with cereal and beef juice, and seven weeks from admission it was well and contented, weighing 12 lbs. and 6 ounces, a gain of three pounds and four ounces.

This case is typical of a fat and sugar intolerance, with a marked dehydration, saved by the

injection of large quantities of fluid at a critical period.

Baby L., age 3 months, weight 13 lbs., entered Stanford Hospital October 2, 1918.

This baby was perfectly normal at birth, breast fed up to the present time. Has always been fussy, and has spit up curds and had rather liquid foul-smelling stools most of its life. A week ago the mother contracted typhoid fever and was admitted to the hospital with her baby.

EXAMINATION.—The baby was very well nourished, but anæmic looking, with dark circles under the eyes. The musculature was flabby, and although the baby was happy, it did not seem to have the activity of a normal baby of its age. Eyes and ears were negative, lungs clear, heart normal. The abdomen was soft, no deep glands palpable, spleen easily felt, liver negative. No rigidity of the neck, skin clear. The stools and a Widal showed no evidence of typhoid. The temperature was 99.2° F., pulse 120, respiration 24. The stools were alkaline, liquid, full of curds, and foul smelling. The baby was put on a formula of: Cow's milk, 18 oz.; water, 16 oz.; milk sugar, ½ oz.

From October 2 to 6 the child did fairly well, but still had curdy, loose stools and a temperature ranging from 99° F. to 102.4° F. On October 8 the baby had lost twelve ounces, began to vomit curds and was put on a skimmed milk mixture. The child at the time looked rather toxic.

On October 8 a formula composed of: Protein milk, 20 oz.; water, 14 oz.; Dextro-Maltrose, ½ ounce.

The following day the temperature went up to 104.8° F., and during the day there were twelve foul-smelling liquid bowel movements. The stools were cultured and contained numerous stripococcal colonies with quite a growth of the bacillus proteus.

At 11 o'clock that night the child was very toxic, restless and moving the head from side to side. The temperature was 100° and respiration 100; no involvement of the lungs. Dr. Langley Porter was called into consultation and made a diagnosis of a toxemia, with split proteid intoxication.

The following treatment was carried out. The bowel was washed out twice daily, with two quarts of water containing two drams of sodium bicarbonate and Murphy dripe of 5% glucose were given. Milk was discontinued and a formula of Dextro-Maltrose, 2 tablespoonfuls; water, 20 ounces; three ounces every two and a half hours were given.

The next day the child was very much improved and a tablespoonful of breast milk was added to the mixture. Two days later the bowel movements were formed, soft yellow, and the baby was non-toxic. On December 2, a month later, the baby left the hospital on a whole milk mixture in good general condition.

This case is an excellent example of a baby having an intolerance for proteids, which was corrected by giving carbohydrate feedings.

THE MEANING OF THE PASSAGE OF INTRAPARTUM MECONIUM.*

By MARGARET SCHULZE, M. D., San Francisco
Instructor in Obstetrics and Gynecology, University of California Medical School.

The significance of the passage of intrapartum meconium has been a matter of interest to obstetricians for many years. Unfortunately at the present time there is no unanimity of opinion, although the great majority agree that in vertex presentations it is a sign of grave moment and indicative of impending fetal asphyxia. All unite, however, in stating that it is of no significance in breech deliveries. Some believe that the sign is of uncertain value, yet others believe that it constitutes an indication for immediate delivery if it can be done without adding to the risk of the mother. Our interest in this matter has been aroused by the large number of cases which passed intrapartum meconium just before labor, but which gave no other evidences of danger either by change in the rate of the fetal heart or by being born in asphyxia. Seeking to ascertain the true value of the sign, we have reviewed our series of 3700 deliveries and have made a study of the literature.

The first statement on the subject was made by Völtern in 1687, who wrote that the most certain sign that the child is dead in utero is when the umbilical cord tears and when a tarlike material is expressed from the anus, although many children die without this phenomenon. Völtern further states that German midwives had long considered the passage of meconium a certain sign of death. Since then the subject has been reviewed at infrequent periods by a number of authors.

It appears as a result of our study that the majority of textbook authors base their views upon the work of Schwartz, who published in 1858 his work on fetal asphyxia, in which he claimed that if the fetus passes meconium it means, if not death of the fetus, at least danger of its death in the act of birth. This view was considerably altered by Jesse in 1888, who made the first tabulated study of this subject, but whose work appears to have been overlooked. His study was based upon 3340 labors in Ahfeld's Clinic in Marburg. Meconium was passed in 9½ per cent of the cases. Seventy-four children of this series were born dead, seventy-four were more or less asyphyxiated and 176 were born without evidence of asphyxia. As a result he concluded that the passage of meconium alone did not constitute an indication for forced delivery. The subject was again investigated six years later by Rossa in Gratz in 1894 in a comparatively small series of eighty-five cases, which, however, were studied exhaustively. His work more or less confirmed the observations of Jesse. Since beginning our investigations there has appeared a publication on this subject by Gejrot in Stockholm in 1920. This author reviewed the labors of 6435 vertex presentations, in which in-

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

trauterine meconium was passed in 5.6 per cent (369 cases). Eighty-three and a half per cent of the children that passed meconium were not asphyxiated, 10 per cent were slightly asphyxiated, 3 per cent were deeply asphyxiated and 3½ per cent were born dead. Gejrot's study shows that children who pass meconium after rupture of the membranes were more likely to be born asphyxiated than those who had passed meconium before the membranes ruptured. Especially when the membranes ruptured early and meconium did not appear until many hours later was the prognosis very grave. The fetal heart tones were not altered in 80 per cent of his cases. Of the remaining, 20 per cent whose fetal heart showed change during labor, approximately one-half were born either deeply asphyxiated or dead. His study indicated that this 10 per cent passed meconium simultaneously with the appearance of deep asphyxia. In a smaller percentage of cases meconium had been passed early in labor and one could not determine, therefore, whether more had been passed later at the beginning of deep asphyxia.

When we tabulate the study of other authors we find that the percentage of cases which pass meconium during labor varies considerably. Thus Kehrer gives 4 per cent, Gejrot 5.6 per cent, Jesse 9.38 per cent, Rossa 16 2-3 per cent of vertex cases. The study of the literature has impressed upon us the importance of distinguishing between cases which pass meconium prior to labor and which have it dissolved in the amniotic fluid and those which pass it during birth. Fresh meconium is flaky and of the typical greenish-brown appearance. Old meconium is dissolved in the amniotic fluid, to which it imparts a green color. The latter is quite different from that seen when the fetus has become macerated or when blood has become dissolved in the amniotic fluid.

With these points in mind, we have investigated the frequency and meaning of meconium in 3700 cases delivered in the University of California Woman's Clinic. We have found, with Rossa, that when cases were not studied with the definite point in mind the passage of meconium may easily be overlooked; thus in long, difficult labors it would be noted and recorded if it occurred, yet it could easily be overlooked in cases with short, normal labors, thus making its prognostic significance seem more serious than it actually is.

In our last 1300 hospital cases this point has been especially studied, and we found 101 cases which passed meconium during labor, or 7.7 per cent, whereas in the previous 1700 it occurred in only thirty-five cases, or 2 per cent. In 700 cases on the outside service, all multiparae with comparatively short and easy labors, there were but seven cases, or 1 per cent. On reviewing these cases, we found that the prognosis in these three groups did not vary as much as one might expect. Thus, of the 101 cases in the last series of 1300, 73 per cent were born unasphyxiated or with such slight evidences that no resuscitative measures were necessary. In the first series of 1700 cases, 66 per cent of the children that passed meconium required no resuscitation. Of the 700 cases on the outside service, 71 per cent of the babies that passed meconium were not asphyxiated. Eight per cent of the cases noted in the study of 1300 cases were born dead, as were 14 per cent of the first series of 1700 and 13 per cent of the outside service.

Classifying our cases in the groups suggested by Rossa, we find that of the 143 cases, in seventy the amniotic fluid was stained with meconium at the time of rupture of the membranes; in forty-one it was clear at the time of rupture but meconium appeared before the birth of the child, while in thirty-two more it was not noted before the child was born, but the amniotic fluid following the child was discolored.

Of the first group of seventy cases, fifty-two were entirely normal at birth, five showed very slight evidences of asphyxia but soon cried lustily without special efforts at resuscitation; three were moderately asphyxiated, requiring artificial respiration for several minutes; three were deeply asphyxiated, but were resuscitated after prolonged effort, while seven could not be resuscitated. Thus in fifty-seven, or 81.4 per cent, of cases in which meconium appeared in the amniotic fluid at the time of rupture of the membranes, respiration was established immediately, or in a very few minutes, without artificial aid.

Fetal heart changes were absent in the cases which showed no asphyxia at birth. Our study indicates that meconium appearing in the amniotic fluid at the time of rupture of the membranes is usually not accompanied by fetal asphyxia. A few cases, however, presented definite asphyxia, and all of these had changes in the rate and rhythm of the fetal heart.

In a considerable proportion of these it could be definitely determined that the meconium was fresh meconium. In others, old meconium was passed without signs of asphyxia at the time of rupture of the membranes, while later, sometimes after many hours, asphyxia developed from causes not yet operative at the time of rupture. In a few of these it could be determined that fresh meconium was passed at this later time.

Meconium appearing later in labor where the fluid was clear at the time of rupture of the membranes was noted in forty-one cases. The prognosis in this series is considerably more serious, yet seventeen of these cases showed neither changes in the fetal heart nor evidence of asphyxia when born. Six showed very slight asphyxia, making twenty-three, or 56 per cent, of the series in which respiration was normally established without artificial aid. Seven were born dead, six deeply asphyxiated, five moderately so. These were all cases of prolonged, difficult labor, and all showed changes in the fetal heart.

Thirty-two cases showed no meconium before the birth of the child, yet meconium appeared in the fluid following it. Seventeen were unasphyxiated, five slightly, making twenty-two, or 68 per cent, which required no resuscitation. Six showed

moderate asphyxia, and in three of these there was difficulty in delivering the body of the child, due to large shoulders. The fetal heart was normal when last noted in all of these cases, yet no notes were given in the moment just before birth. Four were deeply asphyxiated, one of these could not be resuscitated, death in this case probably occurring during the operative delivery from compression of a tight loop of cord about the child's neck.

Meconium appearing after changes in the fetal heart seems in a number of cases to signal the development of a very deep asphyxia. In five of the cases of fetal death other evidence of fetal distress had already appeared and operative measures were already being undertaken or normal labor proceeding so rapidly that delivery was accomplished in a very few minutes, but the child, when born, could not be resuscitated.

In other cases fetal asphyxia, even sufficiently severe to end fatally, may develop without the appearance of meconium in the amniotic fluid. This happens particularly in cases where the death of the fetus is due to severe hemorrhage, as in placenta praevia, or from premature separation of the placenta, as has been shown by Altenbach.

If, then, meconium, as in these cases, is not always a sign of very early asphyxia, it is probable that its appearance in the cases which appeared normal at birth is entirely independent of asphyxia. This probably holds true especially in the cases where it appears on rupture of the membranes, since fetal distress rarely develops in the first stage. In any consideration of the subject it appears, then, necessary to review the influences which might act on the child through the mother, such as toxic states of the mother or of drugs administered to her.

Since the time when Porak in 1875 stated that the administration of quinin was frequently followed by meconium, the view has held that its administration causes physiologic changes in the fetus, which are followed by the passage of meconium, yet both Porak, and subsequently Runge, showed that, although meconium frequently appeared during the expulsive period, there was no slowing of the fetal heart and the forewaters were uniformly clear. As castor oil and quinin are frequently employed to induce labor, we have thought it of interest to review the meconium cases in 385 of our cases in which labor was so induced. Only 6.5 per cent, or 1 per cent less than the meconium of our total series, passed meconium subsequent to the administration of castor oil and quinin. The dosage usually given is .6 of a gram of quinin repeated in an hour, following 30 cc. of castor oil. The castor oil administered to the mothers also had no effect upon the child, nor did any other cathartic which was administered early in labor.

Nitrous oxide analgesia was used in practically all of the 1300 cases for varying periods of time. Nitrous oxide anaesthesia and in a few cases ether were used where operative delivery became necessary. No effect of the anaesthesia on the passage of meconium could be observed. Toxemia cases which presented elevated blood pressure and urinary findings have been considered, but we have been unable to find that there is an increased number of cases passing meconium in mothers showing these evidences of toxemia. Rossa has suggested that severe infectious diseases in the mother might influence the child and cause it to pass meconium. In a study of forty-five cases which developed influenza during pregnancy or labor in the recent epidemic, none showed meconium during labor.

The size of the child is a matter of some interest, since previous authors have found that the weight of the children presenting meconium usually fell within the normal limits of weight. Seeking to follow out Rossa's contention that an overdeveloped child might pass meconium during labor because the bowels became too full, we have reviewed the weights of our series. We have taken as large or postmature one which weighed 4000 grams or more. The average incidence of children of this size in our clinic was found by Dr. Maxwell to be 4.3 per cent, while 22 per cent of our total meconium cases were children of this weight, thus showing the high proportion of overdeveloped children passing meconium during labor. (Many of these were one to four weeks overdue, but only 23 per cent of this series had labor induced with castor oil and quinin, while 20 per cent of the whole meconium series had received castor oil and quinin.) The percentage of asphyxia in the larger children who passed meconium is not greater than in the smaller children, since 80 per cent were born normal or with very slight asphyxia. Deeper asphyxia, which we might expect as a result of more difficult labors, was even rarer. There were no deaths in the postmature series and only one was deeply asphyxiated, a child which weighed 5250 grams and which was delivered by a difficult high forceps. A number of the cases of moderate asphyxia had had difficulty in delivery from impaction of the shoulders.

As a result of our study, we seem justified in presenting the following conclusions:

The passage of meconium by the child during labor is in a large majority of cases entirely independent of fetal asphyxia. The passage of old meconium at the time of rupture of the membranes is of no prognostic value as to the later development of asphyxia. Fresh meconium, with rupture of the membranes or later in labor, may or may not be associated with asphyxia. In the latter case changes in the fetal heart sounds are present also. Meconium appearing after other signs of fetal distress is frequently a sign of the onset of very deep asphyxia and the child may perish even though delivery be very rapidly accomplished. A strikingly high proportion of overlarge children pass meconium, in most cases without serious significance. The cause of the passage of meconium in cases without asphyxia cannot as yet be definitely stated.

DETERMINATION OF THE EXTENT AND NATURE OF THE RENAL LESION IN BRIGHT'S DISEASE *

By THOMAS ADDIS, M. D.

(From the Medical Department of Stanford University Medical School, San Francisco)

This year Christian has collected in a text book [1] a summary of the more important facts which have been established as to Bright's disease. He and his collaborators have made careful and extensive investigations with the most recent methods and his critical review of our present position therefore carries great weight. When I had read it I looked up Bright's Medical Cases,[2] published nearly a century ago. The differences were interesting. One of the most striking was the presence in the modern treatise of many tables of figures giving the results of functional tests. There were no figures in the old book. Yet Bright had noted the existence of changes in the volume of urine and in the amount of albumen it contained. He had even in certain cases observed that the amount of urea in the blood was increased, though at the same time there was less than usual in the urine. In another type of case he had noted the existence of lipemia and of a decrease in the protein content of the blood. We are now able to give a quantitative numerical expression to these qualitative observations of Bright's. But this difference is, after all, often only superficial. No one, I imagine, would be more ready than Dr. Christian to admit that our modern exactitude of expression does not necessarily carry with it any greater knowledge than Bright possessed as to the origin and significance of the changes we can now follow so closely.

But there was another and a more fundamental difference between the new and the old. It lay in the attitude taken towards the relation between function and structure. The modern point of view, and I believe this fairly represents the feeling of those who have had most experience, appears to be that it is illusory to attempt to draw anatomical deductions from our clinical observations and functional tests. Bright would never have subscribed to this opinion. The sub-title of his book is, "illustrating the symptoms and cure of diseases *by a reference to morbid anatomy.*"

It was to anatomy, not to physiology, that he looked for the clue to treatment. He studied functional abnormalities in his patients as aids towards the construction in his mind of a clear picture of the structural defects from which they arose. He believed that as experience accumulated it would be possible for the physician to see through the varying symptomatology and changing functional reactions to the hidden anatomical cause. But as a matter of fact, as experience has accumulated, as methods which supposedly measure the functional capacity of the kidneys have developed, the discrepancy between clinical predictions and post-mortem findings has become more and more apparent.

The recent review I mentioned admits the impossibility of making an anatomical diagnosis. During the last decade there has been a tendency not only to admit this fact, but to set it aside as of no moment. We are now inclined to take the results of functional tests as ends in themselves and not as means towards an anatomical diagnosis. We comfort ourselves with such statements as, "It is more important to know what the kidney can do than to be able to say what it looks like," and so on.

This modern spirit of resignation in failure is due not only to a deeper knowledge of the difficulties of the task Bright set, but in part at least it rests on a satisfaction with our new functional methods. Even if it must be admitted that our results are not always in accord with anatomical findings, we can say that that may after all be due to the inadequacy of histological technique. It is easy to point to special instances where this is certainly true. It is easy for the clinician to believe in his methods and to wait with patience for the anatomy of the future to come into line with his clinical physiology.

There is, of course, plenty of evidence that the present divorce between clinical and pathological findings is in part due to the inadequacy of clinical and not of histological methods. For instance, in circumstances where there is no possibility of any structural abnormality invisible to the microscope, in cases where the renal tissue is entirely normal, we can remove half of that tissue from the body by taking out one kidney, and yet find that the results of the methods now in use will still lie well within the range of normal variation. If our methods cannot tell us when half the renal tissue has been removed, it is clear they are not able to tell us how extensive has been the destruction of tissue in a case of Bright's disease. Yet this is a practical anatomical question which may be of great importance for treatment and prognosis.

It should not be impossible to develop a functional method which would answer this question; for it is axiomatic that functional activity can manifest itself only through and by means of structure. It should be possible to find conditions under which functional activity is limited by structure, so that we could take our functional results as an indirect measure of the amount of secreting tissue present. Since 1913 we have been working at this problem, and as a result of experimental work [3] we have developed a functional method which I believe enables us to make a rough estimate of the amount of actively secreting renal tissue in the living kidney.

The main requirements of such a test became apparent as a result of a study of the factors influencing the degree of variability in the function of the normal kidney. Everyone is familiar with the wide fluctuations in the activity of the kidney, even of the same kidney under apparently identical external conditions. Since the structure is constant, such variations in function must be caused by other than anatomical factors. It was found that no matter how carefully external factors, such as food and water intake, were controlled, there was still a considerable variation in the

* The work on which this paper is based has been aided during the past year by a fund raised by Mr. Wellington Gregg and his friends.

activity of the kidney when measured over short time periods, and that this variation was in part explained by changes in the concentration of urinary constituents in the blood. It was necessary, therefore, to choose some substances whose concentration in the blood could be accurately determined during the period when its rate of excretion was being measured. This substance had also to be one of the so-called "non-threshold" substances, for otherwise changes in the threshold which could not be controlled or measured might influence the results.

We chose urea and studied the factors which induced those variations in the rate of urea excretion which were not to be accounted for by changes in the concentration of urea in the blood. The external requirements of the method were thus determined. But even after the elimination of many disturbing factors, and even though the effect of changes in blood urea concentration had been discounted, there still remained a considerable variability in the rate of urea excretion. It was only when the kidney was put under strain by the administration of large amounts of urea and water that this variability disappeared.

Everyone is familiar with the relative constancy of action of the kidney in terminal cases of chronic Bright's disease, when there is retention of urinary constituents in the blood and very little normal renal tissue left. Normal kidneys show the same constancy when they are given more work than they have ever had to do before, more work than they can at once perform. By giving a large amount of urea by mouth a temporary uremia is produced. Under these conditions all the kidney tissue works at top speed, and the rate of urea excretion is limited only by the amount of actively secreting tissue present.

The details of the test are as follows: The blood urea concentration is first determined in order to find how much urea will have to be given. If, as often happens even in fairly far advanced cases of Bright's disease, there is no increase in the amount of urea in the blood, the patient is given 30 grams of urea, or 20, 15, 10 or 5 grams, depending on the degree of urea retention which may be present. If the urea concentration in the blood is over 75 mgs. per 100 cc., no urea need be given. At 6 a. m. next morning the patient slowly drinks a quart of water in which the required amount of urea has been dissolved, and every hour thereafter drinks two glasses of water. No breakfast may be taken, since protein food has a marked effect on the rate of urea excretion quite apart from its effect on the blood urea concentration. By 9 a. m. the apex of the curve of the raised blood urea concentration is passed and during the next three hours it falls slowly. This is the time during which three accurately timed urine collections are made, and the level of the curve of blood urea concentration determined by analyzing three samples of blood drawn in the middle of each of the three periods over which the rate of urea excretion is measured. From these the rates of urea excretion per hour are calculated and divided by the amounts of urea found in 100 cc. of the blood obtained in the middle of each period. In the same individual under these conditions this ratio remains nearly constant.

In different normal individuals there are constant individual differences. The average ratio for normal individuals is approximately 50—i. e., there is 50 times more urea excreted in one hour's urine than is found in 100 cc. of blood removed while the urea is being excreted. This is independent of the actual level of blood urea concentration. We have a large number of observations of normal individuals, but we are still collecting further data, and it will be some time before it will be possible to determine the probable error of the ratio in normals. We have a series of observations on patients on whom the blood urea concentration and the phenolsulphonephthalein test gave normal results, who yet gave ratios below the lower limit of normal variation. In such cases we believe that the degree of depression of the ratio measures in an approximate manner the degree of destruction of the actively secreting renal tissue. We believe that from these functional results we are justified in drawing conclusions as to the extent of the pathological process in the kidney.

There is another anatomical question often of the utmost clinical importance which is for the most part neglected by the clinician. Prognosis depends not only on the extent but also on the nature of the renal lesion. Inflammatory conditions in which the glomeruli are involved are the most grave, since this type of lesion sometimes progresses until almost no normal renal tissue is left, and even if it heals, always leaves scars. The degenerations are relatively seldom progressive, and on account of the great capacity of the tubules for regeneration, often end in a complete restitution of the secreting tissue. The atrophic lesions, though progressive, are usually so slow that prognosis is good so far as the kidney is concerned. But in making these distinctions, clinical symptomatology is a very poor guide and functional results are of little value. The only method available is the direct one of looking in the urine for anatomical evidences of renal inflammation, degeneration or atrophy. We have, therefore, for some years carried on a systematic investigation of the urinary sediment in cases of Bright's disease. It was soon found that a certain uniformity in the conditions under which the urine was collected was necessary, and since we observed a disappearance of casts in serial observations on cases in whom diuresis was induced by water drinking, we adopted the following plan under which a urine of high concentration is obtained in all except terminal cases of chronic Bright's disease:

The patient is given a wide-necked cylindrical bottle with written instructions to the effect that from breakfast time until next morning, when the urine is collected, no fluids of any sort are to be taken, that at a certain hour in the evening urine is to be voided and discarded, and that next morning the whole twelve hours' night urine is to be

passed directly into the bottle. The urine so collected is allowed to sediment for an hour, and 30 cc. are then carefully pipetted from the bottom of the bottle, special care being taken in so doing that the pipette passes all round the rim and over the whole surface of the bottom of the vessel. The sediment thus collected is centrifuged, the centrifuge inverted at an angle of about 20 degrees so that all of the urine drains off, and the deposit at the tip is removed by a capillary pipette to a slide, while the inverted position of the centrifuge tube is still maintained. If this is not done the urine hanging on the edge of the tube will run back and dilute the centrifuged deposit. In cases where we know that a large number of casts are to be expected we mix up the whole twelve hours' urine and centrifuge in a graduated tube. All but 0.5 or 0.25 cc. of urine is then pipetted off, leaving the deposit undisturbed. After thorough mixing, a drop is placed on a white blood cell counter and from the count the total number of casts in the twelve-hour specimen is calculated. In cases where there are only a few casts they can be counted directly on a slide. In all cases where a sufficient number can be found a differential count of the casts is made. Note is also made of the number of red blood cells, leucocytes, and epithelial cells.

This method has been especially helpful in the diagnosis of glomerular nephritis, the only clinically important form of Bright's disease in which an acute inflammatory lesion is primary. During the early stages, as might be expected, there are large numbers of leucocytes and red blood cells in the urine, but in this there is nothing which can be taken as indicative of glomerular inflammation, since blood and pus are common to an acute inflammatory lesion anywhere in the urinary tract. But there is one form of cast, the blood cast, which I believe is found only in glomerular nephritis. I have not been able to find anywhere a description of the many forms and appearances which blood casts may take. The erythrocytes often become so agglutinated that they are no longer recognizable and only the deep yellow or brownish color remains to indicate the original composition of the cast. It requires some experience to be able to distinguish this form of blood cast from the granular cast, originally epithelial, which is yellow because of the presence of a pigment which appears to be analagous to the pigment found in the cardiac muscle cells in "brown atrophy" of the heart.

But it is especially in the later stages of glomerular nephritis that the finding of blood casts appears to be of special diagnostic importance. We have a number of cases under observation in whose urine a few, sometimes only one or two, blood casts are almost constantly found. In some of these cases there has been a preceding acute glomerular nephritis with general anasarca, but in most of them there is not even a history suggestive of such a condition. If these kidneys could be examined microscopically I believe it would be found that a few glomeruli would show evidence of an active inflammatory lesion. Some of these glomeruli will in time be so damaged as to become functionless and their tubules will degenerate and be replaced by fibrous tissue. As this process extends to other renal elements there will be a slow disintegration of the secreting tissue.

In a few cases which we have been able to follow for some years it would appear that the progress of the pathological process is so slow that the condition may never produce a lesion so extensive as to be of clinical importance. But it seems not improbable that it is these commonly unrecognized cases of focal glomerular nephritis which may be seen for the first time when complete renal insufficiency is impending and in whose small cirrhotic kidneys the pathologist finds evidence that the primary lesion has been a glomerular inflammation.

The cases of Bright's disease in which a degeneration of the parenchyma of the kidney is the primary lesion give evidence of damage to the tubular epithalium in the form of epithalial casts and of the coarsely granular casts which are derived from the disintegration of the epithalial cells. In certain forms, also, the sediment shows many hyeline and epithelial casts with fat droplets. Some of these droplets are doubly refractile. They are not pathognomonic of a fatty degeneration of the renal cells, since we have confirmed Gross's statement [4] that they may be produced in any case of Bright's disease by feeding cholesterol. But this finding is none the less of diagnostic importance, since it is found in a group of cases which form a distinct subdivision of Bright's disease, with its own peculiarities of prognosis and its own special requirement as regards treatment.

Although many instances in which a degeneration is the primary lesion recover completely, there are a certain number, larger I believe than is usually supposed, in which the condition progresses

---

Is It Chiro-Quack-Tic?—Under this heading Leslie's Weekly, beginning with the issue of January 4, is running a series of articles of incalculable value to the public. These articles, written by Mr. Severance Johnson, an experienced writer, are of the same general character that Samuel Hopkins Adams used in "The Great American Fraud" a great many years ago. Not only physicians but every citizen should read these articles and see what they are really invited to support by their ballots and by their co-operation in this and in other States. Leslie's Weekly is rendering the public a splendid service in the publication of these articles, and physicians above all people should read them and pass their copies along for other people to read.

Arizona, California and Nevada Sections of the American College of Surgeons—The first group meeting of the three States was held in one of the hotels of Los Angeles on February 17 to 18. Stanley Stillman of San Francisco, chairman; Lewis R. Morton of Los Angeles, secretary, and Granville MacGowan of Los Angeles, chairman of the committee on arrangements. One meeting was devoted to questions of hospital betterment. There were two scientific surgical meetings, and one morning was given over to clinical demonstrations in Los Angeles hospitals.

to a stage in which the destruction of secreting tissue is so great that the remaining tissues become insufficient for life. We followed one such case through almost its entire course and found in the end a contracting kidney in which the microscopical findings indicated that a degeneration was the primary lesion, and we have several others under observation in various stages of renal decompensation. In none of these cases have blood casts ever been found.

Kidneys in which there is neither an acute glomerular inflammation nor any pronounced tubular degeneration may suffer a slow and partial atrophy which is associated with an arteriosclerosis of the renal arteries. The urine shows a variable number of hyaline casts with an occasional epithelial or coarsely granular cast and only a trace of albumen. The functional capacity is diminished, but we have never yet found any extreme loss of function. It is still uncertain whether this very slowly progressive lesion ever becomes so extensive as to lead to death in uremia. The evidence from the clinical side will have to come from systematic urinary examinations and repeated determinations of the extent of the lesion. Direct and positive evidence of the possibility of such a development would be given if a gradual failure of functional capacity were shown, combined with the development of the typical urinary sediment found in terminal cases of contracted kidney, and this without the appearance at any time of any indication of acute glomerular inflammation or active tubular degeneration.

In cases bordering on or actually in uremia there are a considerable number in which no evidence of active inflammation or degeneration can be found. Instead there are large numbers of casts which vary widely in size, from those with the usual breadth through all stages up to those which are four or five times broader than ordinary casts. I think it is justifiable to regard such broad casts as direct anatomical proof of the dilatation of the tubules which postmortem examination shows in these kidneys. The casts in such cases have a characteristic appearance. Those which might be called hyaline have not the transparency of the ordinary hyaline cast, but seem to be of a denser material, and there are all grades of transition to the typical waxy cast. The granular casts are more granular than usual. Some are composed of a highly refractile material in which what might be the faint outlines of degenerated epithelial cells or leucocytes can be seen, but more often they have an appearance suggesting a loose aggregation of dark particles which appear quite black under the low power, and have not the sharply defined and regular contour which casts usually possess.

The interpretation of these findings is largely dependent on a comparison of the character of the urinary sediment during life with the nature of the lesion as revealed by a microscopical study of the kidney after death. Our postmortem material is as yet small, so that our conclusions can only be provisional. But there is enough to encourage us in the belief that a careful examination of the urinary sediment will often give very direct evidence as to the nature of the lesion in the kidney.

Even though we were always able to determine with accuracy both the nature and the extent of the renal lesion, we should still be far from a real knowledge of Bright's disease; for in Bright's disease more than the kidney is involved, and in some of its forms, prognosis and treatment depend on an evaluation of the condition of the heart, of the vessels and of the effect of the disease on other organs, as well as on an estimate of the state of the kidneys. But just on account of the complexities of these problems it is important, for purposes of analysis, to consider each of the elements separately, and only in the end to combine them in a composite judgment. The renal lesion is one of these elements, often the most important, and this special problem can only be solved when we are able to answer two questions, the question of the nature of the lesion and the question of its extent. I believe that a thorough and systematic examination of the urinary sediment under controlled conditions gives the most direct evidence as to the nature of the lesion, while its extent must be determined by a measurement of the total functional capacity of the kidneys under conditions designed to call forth the greatest possible amount of work of which they are capable.

A FALSE RUMOR

This office is amazed to discover that a rumor is prevalent that members of the Indemnity Defense Fund have been assessed $30 a year since the institution of the fund in December, 1916. This is not true. The first assessment on Fund Members will be levied this year. Those who joined it at its inauguration have had the benefit of its protection for five years without assessment of any kind for that period.

Payment of $15 in cash and the execution of a note in the sum of $15 due one year after date entitles any member in good standing to join the fund.

RECENT ADVANCES IN THE DIAGNOSIS AND TREATMENT OF HAY FEVER AND ASTHMA*

By ALBERT H. ROWE, M. S., M. D., Oakland, Calif.

The investigations of the last ten years have cleared the haze away from the asthma and hay fever problems, so that definite relief is now in store for most sufferers with these diseases. No one now can doubt the fact that these conditions are usually manifestations of protein sensitization or bacterial infection, since recent work shows that both bronchial asthma and hay fever may be due to susceptibility to one or several of the proteins in foods, pollens, animal hairs, bacteria, and several other substances like orris root.

Protein sensitization, moreover, has been shown to cause many cases of eczema and urticaria. All such conditions should be investigated with skin tests especially for foods, and also, if indicated for animal hairs and pollens as shown recently in Walker's article entitled "Causation of Eczema, Urticaria and Angino-Neurotic Edema." A recent case of eczema emphasizes the truth of this statement. In this case our skin tests showed marked susceptibility to most vegetables as well as to wheat, and there had been a vegetable diet prescribed, which, of course, had exaggerated the eczema.

These diseases, then, are the marked examples of protein sensitization, and internists today are wondering about the effect on the body of the slight but constant sensitivity to foreign proteins. Many of the obscure diseases, as suggested recently by Cooke, such as migraine, arthritis, chronic dyspepsia, renal and hepatic diseases may be associated with a chronic anaphylactic state. Gay and Southard have described the marked fatty and waxy changes of muscle, the local necrosis of epithelium, and the fibrous thickening of the glomerular capsule which results from acute anaphylaxis. It is, therefore, very probable that continued minimal anaphylactic shocks can work permanent damage. Therefore, for this added reason, the study of our present knowledge of protein sensitization is most important.

GENERAL CONSIDERATIONS

In the study of hay fever and asthma patients, a thorough diagnostic examination is the first essential to correct and successful management. We must be sure that the asthma is not associated with some lung, heart, kidney or other organic disturbance. Focal infections, especially in the sinuses, teeth, tonsils and pelvis must be discovered and cleared up. These cases, moreover, should all be examined, with the greatest care, by a competent nasal specialist and the remotest possibility of sinus infection ruled out. We feel, however, that operative procedures on the nose should not be done with the idea of a cure of hay fever or asthma without a careful diagnostic study by an internist, who can not only rule out the presence of organic disease, but also discover the presence or absence of protein sensitivity. Otherwise much unnecessary and sometimes dangerous nasal surgery will be done as, for instance, in the case of a recent patient, who gave a most marked reaction to orris root, which is found in nearly all face powders, and where the nose had been thoroughly operated on from all angles, without the slightest relief.

To determine the fundamental cause of hay fever or asthma, skin tests with the various proteins of pollens, animal hairs, foods, bacteria, orris root and certain other substances in selected cases such as boxwood dust are absolutely necessary. These tests have been shown to be specific, and the whole procedure in the large part is out of the experimental stage, ready for the physician who wishes to give his asthmatic or hay fever patient as good and scientific treatment as is possible. In our work over 2,400 separate tests have been made on over ninety different patients and reactions have been obtained to nearly all kinds of foods, including fruits and vegetables. The technique of Walker and his suggestions as to the interpretations of the scarification method of skin testing have been followed explicitly since the intradermal method has certain disadvantages such as the danger of anaphylactic shock, the inability to do any large number of tests at any one sitting, and the inconstancy of some of the reactions. The so-called delayed reaction, which shows up twenty-four hours after the test with a tender, reddened area often slighthly purulent, has been watched for in all cases. The very positive reactions present a most definite urticarial wheal with amœba like pseudo-podea and a red areola around about. We have obtained the most marked reactions with the pollen, animal hair, shell fish, wheat, and orris root proteins, though occasionally other proteins such as those of carrot and onion give striking results.

The manner in which these proteins produce their symptoms is a matter of the greatest conjecture. Why one person will have hay fever and another will have asthma from pollens, is surely a problem. Undoubtedly the cells of the entire epidermal covering of the body are sensitized to the proteins. Whether the asthma is due to a vagotonia or whether the mucous membrane of the bronchi becomes swollen and congested in the same way that the nasal mucosa does in hay fever is not settled.

Koessler feels that these conditions may be manifestations of a poisoning due to toxic amino acids which the body cells have split off from the proteins of pollens, food, bacteria, or animal hair. Thus, the unknown is ever stretching ahead of us in our medical studies.

HAY FEVER

That certain types of hay fever are caused by pollens was first suggested by Blackley in 1873 in "Experimental Researches on Hay Fever." He was able, to his own satisfaction, to explain the production of such symptoms by animal hair by the probable carrying of grass pollens in the fur of the animals, but his theory broke down when he attempted to explain the action of food in the production of this condition. In 1905, Dunbar proved that hay fever could be produced by the

* Read before the Alameda County Medical Society, Oakland, May, 1921.

inhalation of pollen, and tried to treat patients with pollen injections. Since then, through the work of Noon and Freeman, Clowes, Goodale, Cooke, Koessler, Scheppegrell, Walker, and Selfridge here in California, the present knowledge of the cause and treatment has evolved.

It is now certain that hay fever symptoms are due to susceptibility to proteins not only of pollens but of animal hairs, foods, bacteria, orris root and certain other substances. The patient's history will usually suggest which proteins are the most likely cause. However, though pollens cause most seasonal hay fever, certain of the summer coryzas, we have found are due to animal hairs and especially to bacteria. Again, bacteria or foods cause most of the all-year hay fevers, though it is well known that pollens may be at the basis of certain of these disturbances. Hence, no set rule can be laid down in regard to the character of the proteins which are to be used in testing any definite case. The physician doing this work must be prepared to test with all the proteins to which the patient is exposed.

For our work we have available the proteins of 86 foods, 8 animal hairs, 15 bacteria, 74 pollens, and that of several sachets, perfumes and orris root. The proteins of food, animal hair and bacteria have been purchased through commercial houses and they seem to be very satisfactory. As Selfridge[3] has shown, however, the commercial pollens are useless for our work here in California, since this flora differs absolutely from that of the East, as shown by Professor Hall, and there are apparently many more hay fever-producing grasses and shrubs here than there. Hence, we have collected the pollens of the hay fever-producing grasses, shrubs, weeds and trees of this region of California ourselves, and have them available for diagnosis and treatment.

The recent articles of Walker have crystallized the thought on this subject, and we have conducted our work along lines suggested by him. He classifies the causes of hay fever and asthma in the following diagramatic way:

Causes

Sensitive		Non-Sensitive	
Seasonal	All year round	Seasonal	All year
Pollens	Hair	Bacteria	Bacteria
Foods	Food		
Bacteria	Bacteria		
Animal hair	Pollen		

Much difference of opinion exists at present, concerning the best method of diagnosis and treatment of hay fever due to pollens. Scheppegrell thinks that one representative of each of his so-called biological groups of pollens is sufficient to use for diagnosis and immunizing purposes. Selfridge and probably Goodale, however, feel that there is a marked specificity for the individual pollens of the various species, and the former contends that immunization with each pollen to which the patient is susceptible is necessary for success. The hay fever pollens are probably much more profuse in California than in the East, and our own experience would indicate a marked specificity for each individual one.

For immunizing purposes, Walker and Goodale[4] use strong dilutions finally in getting their good results, while Scheppegrell[5] and certain others recommend small doses. Our work confirms Walker's experience, and doses of strong dilutions are gradually administered, the dosage being controlled by skin tests. It is most gratifying to see the positive skin test to pollen protein gradually disappear with careful treatment. However, such immunity, it should be remembered, must be re-established each year, though it is hoped it may become permanent with successive immunizations. When the patient is sensitive to foods, removal of the food is usually effective. We have not attempted to immunize patients with hypodermic injections of wheat, but have recommended in several instances the gradual feeding of the offending food proteins, beginning with one-half milligram and working the dose gradually up to several grams. In regard to this food idiosyncrasy, we must remember, as Talbot has pointed out, that it often gives way to pollen or animal hair sensitiveness later in life. Horse dander susceptibility has been treated with gradually increasing doses of horse dander protein subcutaneously. Feather protein sensitivity has been taken care of by substituting floss pillows and mattresses for feather ones. Orris root symptoms require the use of rice powder if the patient is not sensitive to it, since nearly all commercial face powders contain orris root. Bacterial types of hay fever require the isolation from the sputum or nasal secretion of the offending organism and the preparation of an autogenous vaccine from it, especially if it is a streptococcus or any other organism than a staphlococcus or diphtheroid, in which latter cases Walker feels autogenous vaccines are not necessary.

To appreciate the results which can be obtained from such therapy, one must consult the most excellent articles of Walker entitled, "Frequent Causes and Treatment of Perennial Hay Fever" and "Sensitization and Treatment of Bronchial Asthmatics with Pollens."

We have made a study of twenty-six cases of hay fever seen in my private work, and in these cases there have been:

13 instances of seasonal pollen sensitiveness;
10 instances of bacterial sensitive and non-sensitive types;
6 instances of susceptibility to pollens, foods, and bacteria;
3 instances of sensitiveness to animal hairs as well as to pollens or bacteria;
9 instances of susceptibility to orris root;
1 instance of sensitiveness to beef protein;
2 instances of sensitiveness to chicken feathers alone.

To illustrate the diagnosis and treatment of seasonal hay fever due to pollens alone, the following case will be summarized:

E. M., a woman, age 30, has had hay fever of the most severe type for eighteen years, always from February to September. Constant running of eyes and nose, sneezing on arising in the morning, and for one-half to one-hour periods during

the day occur. Suffers with terrible dryness of the throat and itching of the nose and eyes. Cannot go out into the country or fields or even into the night air. Feels bloated and swollen at times as well as feverish, and often large wheals come out over body. All symptoms disappear on going to San Francisco or into the high Sierras. The father has had hay fever for forty years and many of his people have catarrh.

Cutaneous tests showed marked reactions to one to five hundred dilutions of the pollens of poa annua, oats, canary grass, wheat, fescue, Kentucky blue grass, barley, rye, brome, velvet, beard grass, timothy, mugwort, oryzopsis, and moderate reactions to white top, sage brush, dock, rag weed and poverty weed.

Immunization given for two months last year, with gradually increasing doses of the dilutions of these pollen proteins, relieved her of her hay fever for the first time during July and August for years. She has gained thirty pounds and feels better than she has for years. She is now able to ride and walk in the country, and can go out at night.

Other cases of this type could be cited. Our experience, in brief, indicates that pollen hay fever can be relieved by correct immunization with pollen dilutions to which the patient is susceptible. It is possible, in our minds, that the pollens of certain flowers such as the daisy, aster and cineraria can cause hay fever, providing enough of the flowers are grown in a given locality. A patient's house was recently found to be surrounded by Shasta daisies to which pollen she gave a tremendous reaction, and even though other grasses were found to be positive, immunization to Shasta daisy as well as the grasses was carried out.

The non-sensitive seasonal bacterial type is illustrated by the following case:

R. B., a man, age 31, has had attacks of running of the nose, itching and congestion in nose, and sneezing lasting about one day. Attacks occur usually in the summer. Sweeping always brings on attacks, and they come with nearly every cold. Asthma may come with a cold for about two days.

Shell fish has always poisoned him. Lips, tongue and throat swell, stomach becomes unsettled, and he vomits and feels very ill after eating even a small amount.

Cutaneous tests with all the foods he eats except for shell fish as well as animal hairs, orris root, and pollens were entirely negative.

He, therefore, is an example of the seasonal non-sensitive bacterial type of hay fever, and will probably respond to the autogenous diphtheroid vaccine which we have prepared for his treatment.

A most interesting example of the sensitive bacterial all-year-round type of hay fever as well as of the marked horse dander hay fever is as follows:

G. G., a woman, age 21, has had sneezing every morning until noon for the last eight years, following a severe attack of bronchitis. Sneezing often is steady and lasts into the afternoon, and may awaken her at night for one-half to one hour. Nose runs terrifically, and nose and roof of mouth itch. Has tightness in her chest, and breathing is never easy. Feels tired and drowsy all the time. She also has had a typical hay fever and wheezing when she has been around horses, for the last three years. She becomes so ill and tired, and eyes and nose itch and run so much that she must go to bed after being around them.

Cutaneous tests were positive to staphlococcus albus and strongly positive to horse dander and horse-hair protein. To all other proteins her tests were negative. Cultures of her abundant nasal secretion showed a pure culture of staphlococcus albus, and three injections of the autogenous vaccine, prepared by my bacteriologist, Miss Margaret Eakin, relieved her completely. For three months she has been free from all symptoms. We are also immunizing her carefully to horse dander proteins, and feel confident that she will be able to be around horses again without trouble.

An example of food sensitiveness accompanying pollen susceptibility, follows:

A woman, age 30, has typical hay fever beginning in April and lasting through July. She is susceptible to several of the spring pollens, and also to many of the green vegetables. We feel that the limitation of these vegetables in her diet is most important. She is being immunized to the pollens to which she reacted.

A most striking example of orris root and non-sensitive bacterial hay fever, follows:

F. S., a woman, age 24, has had attacks of swelling of the nasal mucosa, marked coryza and watering of the eyes, marked swelling across the bridge of the nose and swelling of the eyes, for the last three years, coming every few days. She has been unable to use orris root as a shampoo, and is unable to ride on a street-car or go into a room with women who have used face powder. With severe attacks she gets marked throbbing in nose and over her eyes, and is so miserable that she has to go to bed. Her nose has been operated on several times, with no relief. During the last year her hay fever symptoms have persisted, and during the last few months she has been having asthma.

Cutaneous tests were negative to all proteins except orris root, to which she gave a tremendous reaction.

When she does not come in contact with face powder she is fairly comfortable, though her symptoms have persisted, probably due to a secondary nasal infection. We feel that when she is immunized to the staphlococcus aureus, which Miss Eakin has found in her sputum, she will get complete relief.

These examples of the various proteins which can cause hay fever, show the propriety of the suggestions of Cooke to call this disease "protein rhinitis." Our work confirms the idea of multiple sensitization and specificity of proteins in hay fever, and shows the futility of doing hay fever testing here, with anything except a full supply of California pollens, foods, hairs and bacteria. We feel that this work moreover, can best be carried out by a trained bacteriologist, who can make free and frequent use of bacteriology with the minimal expense to the patient.

ASTHMA

Meltzer probably first suggested, in 1910, that bronchial asthma is due to an anaphylactic state. In 1912, Schloss[6] first demonstrated that specific sensitization to foods existed in man, and that the skin test could be used to determine this susceptibility. His work was extended by other investigators to urticaria and eczema and laid the foundation for the memorial series of studies, which Walker has published during the last four years.

In these twenty-seven or more articles, Walker reports his scientific investigations on his large

series of asthmatics and shows in careful detail the manner of treating nearly every type of case. No one interested in this subject should miss a careful study of all these articles.

His articles in the "Oxford Medicine" summarizes many points which are important to mention here.

Walker states that true bronchial asthma is an anaphylactic phenomenon, resulting from some foreign protein. Asthmatic bronchitis, however, is the result of prolonged respiratory infection and produces dyspnœa, bronchitis, and coughing at night due to the accumulation of a sticky sputum. Often asthmatic bronchitis is superimposed on true bronchial asthma, this occurring early in cases in children due to the susceptibility of their mucous membranes to infection.

Walker, as previously stated, uses the cutaneous skin tests rather than the intradermal one. A positive test for a protein may not mean that that protein is causing the asthma, but it does point out a danger which should be kept in mind. Omission of a food from the diet may desensitize a patient and change a positive test to a negative one. Hence, it is important to be eating the foods for which tests are done and to repeat slightly positive reactions. Bacteria may give a negative test for protein sensitiveness, but may still cause asthma due to their infectious nature alone.

Of six hundred asthmatics, Walker found 48 per cent sensitive to some protein, and 52 per cent non-sensitive. Sixteen per cent of the 600 were sensitive to animal emanations, mostly to horse protein. Twelve per cent were positive to foods, wheat, egg, potato and fish being the most frequent in succession. Ten per cent were positive to bacterial proteins, the staphlococcus aureus, streptococcus hemolysans and hemolyticus, staphlococcus albus, and streptococcus viridans being the order of frequency. Micrococcus tetragenous, diphtheroid, and other bacteria also give positive reactions. Eleven per cent gave positive tests to pollens. Pollen asthmatics often have a secondary bacterial bronchitis.

Walker shows that as the age of onset of asthma increases, the frequency of sensitization decreases and the frequency of non-sensitiveness increases, the latter being universal after the age of fifty. After forty, occupations such as baking, tending horses, or sifting coffee beans are apt to bring on asthma due to the exposure to the specific proteins. Each sex, all ages, and all races are equally susceptible to asthma. The longer the duration of asthma, the more pronounced is the resultant bronchitis and emphysema and the more difficult the relief. Multiple sensitization occurs most frequently in youth and sensitization to one protein is apt to be followed by another later on. Eczema is usual in youth where a food susceptibility is present. Heredity was positive in about 48 per cent of all asthmatics.

In regard to treatment, Walker states that high temperature destroys anaphylactic properties of food so that toasted bread, baked potato or boiled milk may be given to people susceptible to the proteins of these foods. Patients, moreover, may be able to eat small amounts, but not large amounts of certain foods. Eighty per cent of the sensitive cases are relieved by protein therapy, and another 10 per cent are relieved by vaccines. At least two-thirds of the non-sensitive asthmatics are relieved by vaccine therapy, or we must try another organism if the vaccine fails. Operations will not relieve the sensitive types, and surgery should only be done in the non-sensitive types to remove the foci of infection or promote drainage. Change of climate will help the non-sensitive patients, but not the sensitive ones, unless they are susceptible to pollens.

We will conclude our article with the analysis of thirty-eight cases of asthma, which have been referred to me in my private practice. Of these cases there have been:

23 cases of the sensitive and non-sensitive bacterial type.
6 cases of the bacterial and food sensitive type.
2 cases of the bacterial, food and animal hair type.
2 cases of animal hair type alone.
2 cases of the food type alone.
2 cases of the pollen and bacterial type.
2 cases of the pollen type alone.
1 case of the bacterial, food and pollen type.

A brief summary of some of the histories and methods of therapy will be given.

Three cases illustrative of the bacterial type of asthma will be summarized:

M. M., a woman, age 25, has had asthmatic wheezing continually since she was eight years old. Since the age of sixteen, it had been so distressing in the winter that she had to come from her home in Seattle to California. She has never raised any sputum. Severe attacks are frequent. She has been unable to ride horses for some years on account of the exaggeration of her asthma.

Cutaneous tests were negative with the exception of a moderately positive reaction to horse dander. X-rays of sinuses showed a right maxillary sinusitis and an abscess at the root of the first upper right bicuspid. The extraction of this tooth and drainage of the antrum together with several injections of pituitary and adrenalin extracts at the time eradicated the asthma, and she has been free for two years. Her susceptibility to horse dander proteins was not sufficient to give any symptoms unless in close contact with horses.

F. W., a woman, age 35, has had a dry hacking cough associated with a wheezing bronchitis with exaggerated spells of bronchial asthma with acute colds, continually for twenty years.

Cutaneous tests gave a marked reaction to streptococcus hemolyticus and were negative to all other proteins.

X-rays of teeth showed a definite apical infection of four teeth. These were extracted and her infected tonsils were removed also.

Cultures of the tonsils gave a pure culture of streptococcus hemolyticus and the asthma which persisted for two months after the teeth and tonsils were removed, cleared up when careful immunizaton with the vaccine was carried out. She has remained entirely free from her asthma for over one year.

This case shows the necessity of desensitizing the patient to the bacteria which is producing the trouble, especially when a specific skin test is

present, even after the harborers of the bacteria have been removed.

E. B., a woman, age 52, has had asthma following pneumonia nearly continuously for twenty-four years with exaggerated attacks with colds. Raises much sputum. Occasionally sneezing and running of the eyes and nose occurs.

Cutaneous tests were negative except to staphlococcus aureus and orris root. Cultures of the sputum yielded a pure diphtheroid and immunization has given her marked relief for the last eight months.

Two cases of combined food and bacterial sensitiveness will be mentioned:

M. W., a woman, age 40, has had bronchial asthma continuously since childhood. As a child had hives.

Cutaneous tests were positive to wheat proteins and to orris root. Cultures of sputum showed a streptococcus and diphtheroid. Cutting the wheat from her diet and immunizing her with the vaccine is giving her relief.

G. H., a boy, age 6, has had very severe attacks of bronchial asthma since the age of six months, when vegetables were first added to his diet. He has always been wheezy and unable to play or run.

Cutaneous tests were markedly positive to carrot, corn and onion proteins and to staphlococcus aureus. His sputum yielded a pure culture of staphlococcus aureus.

Elimination of carrots, corn and onions from the diet did not relieve his wheezing until immunization to an autogenous staphlococcus vaccine was carried out and since then he has had relief. For the first time in his life he is able to play and run like other boys.

These last two cases illustrate the type which is originally sensitized to food proteins and where asthma becomes chronic because of an added bacterial infection.

One example of asthma due to foods alone is given:

B. W., a boy, age 8, has had many frequent attacks of bronchial asthma for several years.

Cutaneous tests showed marked reactions to carrots, rice and peanuts. Dr. Clifford Sweet reports complete relief since these foods were eliminated, with the exception of a slight attack when he broke over his diet.

An interesting example of susceptibility to foods, pollen and bacteria is cited.

P. T., a boy, age 10, has had severe attacks of asthma every ten or twelve days for the last three years and has never been absolutely free from difficult breathing. He has very little sputum.

Cutaneous tests gave positive results with the pollens of Kentucky blue, poa annua, barley, wheat, agrostis, and timothy grasses. Tests for wheat proteins, as well as wheat glutenin, leucosin, and globulin, corn, barley and beef proteins showed marked so-called delayed reactions. All other reactions were negative.

Immunization to the pollens, together with the elimination of the foods to which he was sensitive, and immunization to an autogenous vaccine, consisting of a streptococcus, gram negative diplococcus and staphlococcus aureus has given definite and gratifying relief. He can now play ball for the first time since asthma began.

In conclusion, certain points should be emphasized to assure correct diagnosis and success in the treatment of cases of hay fever and asthma.

1. A complete stock of proteins of foods, animal hairs, orris root, bacteria, as well as a large number of our California pollens is the first essential for correct diagnosis and treatment.

2. Ready access to a competent bacteriologist who can carefully prepare vaccines as needed for the treatment of these cases, is important.

3. The pollen type of hay fever receives marked relief by proper pollen therapy and this should be given with the local pollens only.

4. The bacterial types of asthma and hay fever receive striking and often rapid relief with autogenous vaccines.

5. Food types of these illnesses must be treated with absolute removal of the foods to which sensitivity exists to get results. Desensitization may then be tried.

6. Surgery is important if foci of infection are present or drainage is imperfect.

7. The writer feels that if care is taken and the patients co-operate, most of these sufferers can receive either partial or complete relief from hay fever and asthma.

STYLOID PROCESS IN TONSILLECTOMY

By J. A. BACHER, A. B., M. D., San Francisco

From the Subdivision of Otology, Rhinology and Laryngology of the Division of Surgery of the Stanford School of Medicine.

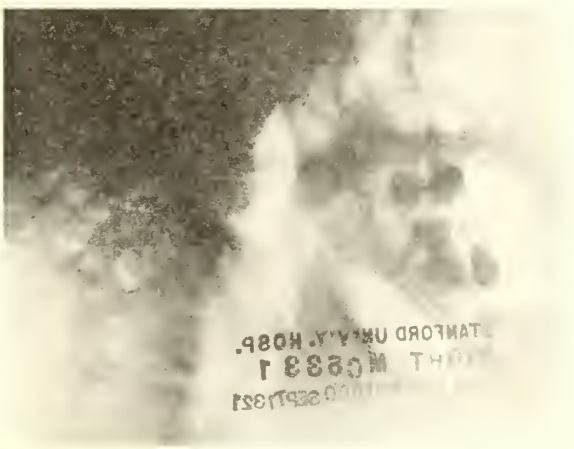
During the past five years two cases of elongated styloid processes, presenting in the tonsillar fossæ, have come under my observation. In neither of the cases was the diagnosis made before tonsillectomy. In the first case inspection of the fossa after uncomplicated tonsillectomy showed a sharp prominence covered with muscular tissue extending from above downwards rather close to the anterior pillar. In the second case a snare wire was placed around the process and an X-ray picture taken with the wire hanging from the process. Convalescence was uncomplicated in both cases.

I have found fourteen cases in the literature. Ten were discovered previous to operation and four on account of difficulty in the operative procedures. The prominence was removed with bone forceps in four cases. The characteristic movements that the styloid process, alone of the possible bones in this position, possesses are first that it moves with rotation of head, and second that it moves with nodding of the head.

In the cases discovered before operation there were exaggerated symptoms of chronic tonsillitis. In these cases part of the process has been removed with bone forceps. Other cases have caused difficulties in instrumentation. These cases deserve publication, as it is not commonly known that the styloid process can be so long.

CASE I—Elongated styloid process.

CASE II—Taken fifteen minutes after uncomplicated tonsillectomy. Wire snare hanging suspended from tip of styloid process in base of tonsillar fossa.



Normal Styloid Process.

WALTER LINDLEY, M. D.

(Born Monrovia, Indiana, January 13, 1852

Died Los Angeles, January 24, 1922)

Dr. Walter Lindley was one of the most widely known and most beloved physicians of the West. He was educated in Minneapolis and received his Doctor of Medicine degree from the Long Island College of Brooklyn, N. Y., and subsequently attended Keen's School of Anatomy, Philadelphia. He had been engaged in practice in California since 1875. During that time he was an outstanding figure in the medical world and became influential in the civic and economic affairs of the State. He had held all of the positions of honor that could be given to any member of his profession in California, and he was also a member and a director of the Los Angeles Chamber of Commerce. A number of banks and trust companies were honored by his membership on their boards of directors, and he was noted for his friendship and assistance to young men in all walks of life during the period when they were striving to get started in their careers.

Dr. Lindley leaves a widow, three daughters and one son, Francis Haynes Lindley, together with a host of warm personal friends who mourn his passing.

GLUCOSE AND ALKALIES IN SURGERY

By ALANSON WEEKS, M. D., and LEROY BRIGGS, M. D., Surgical Department, University of California Medical School, St. Luke's Hospital

The age of empirialistic medicine is practically closed. The present tendency is to find and remove the pathology of the disease instead of rendering symptomatic treatment. So much is this true that some of us stand so straight as to fall over backward, forgetting, at times, that: There is a patient who has the disease as well as the disease which the patient has. This is the natural sequence of the revolution which our medical schools have undergone. There is a striking difference in the courses of the modern school when compared with those of a few years past, and more especially is this true of pharmacology and therapeutics. Today stress is laid upon a few drugs of proved value, and possibly these proofs are too often entirely laboratorical. Fortunately, however, the importance of sanitation and proper nourishment is emphasized. Carbohydrates are our simplest foodstuffs and of these glucose is the simplest form, and its indications and methods of administration are definite. We shall not proceed with the chronological development of the details of the uses of glucose as is usual in such discussions, but shall endeavor to stick to the practical side of the subject. It will be necessary, however, to recall some chemical properties and the physiological activity of glucose to appreciate fully its indications and usefulness.

Glucose is a monosaccharid, crystalloid substance, forms true solution, diffusable through semi-permeable membrane, and, therefore, in solution, obeys all the laws of osmosis.

Physiologically, glucose is the form in which the carbohydrates are absorbed from the intestines after digestion is complete. It is taken up by the blood and transmitted to the liver, then to the tissues, to be utilized or stored (mainly in liver and muscles) in the form of the polysaccharide, glycogen. This store of glycogen is called upon when the katabolism exceeds the anabolism, as in starvation. This is the food of choice or organism. It has been shown repeatedly that the glycogen content of the liver and muscles is decreased during starvation, and also that further starvation results in an increase in the elimination of nitrogen proving a destruction of protein tissues of the body. The glucose is oxidized, forming compounds of lesser number of carbon atoms, which are further oxidized, so that the final metabolic products are carbondioxide and water, which is excreted by lungs, kidneys and skin.

Before proceeding further we wish to state that we are ardent advocates of the alkalinization of patients. All cases get an alkaline water before and sodium bicarbonate after operation.

INDICATIONS AND METHODS OF ADMINISTRATION

Glucose solution by rectum is indicated in all cases of dehydration and those who cannot take fluids or food for three days or more. This means, then, all cases of major operations, and more especially those in which the peritoneal cavity is opened. After any major operation there is a slight increase in the rate of metabolism evidenced by a slight rise in temperature due to increased nerve tension, absorption of toxins, products of antolysis of strangulated tissues, etc. At this time there is an increase in the katabolism and a standstill in the anabolism if the patient is not taking food. This results in a call upon the glycogen reserve first and tissues protein later if the glycogen is not replaced. This gives us a definite indication for carbohydrate food and it is best administered in the form of glucose, which will keep up the supply of glycogen with a minimum amount of dissipation of energy on the part of the patient. Five per cent glucose and 5 per cent sodium bicarbonate solution by rectum is used because this strength solution is practically isotonic with the blood and is readily absorbed.

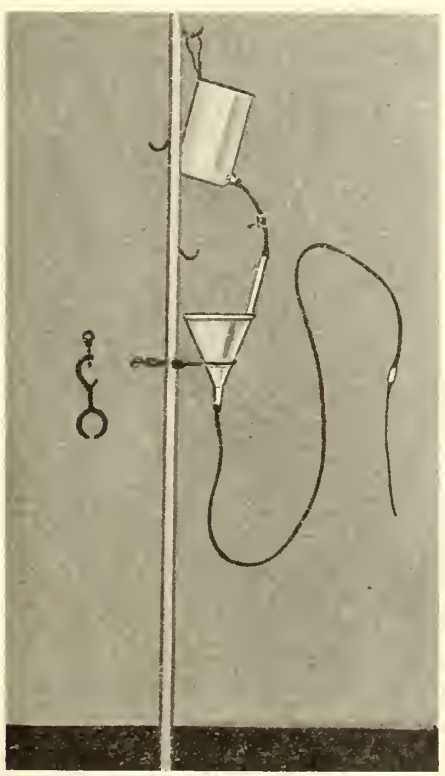
We hear an occasional objection by a physician on the ground that the solution irritates the patient and cannot be continued. This can readily be overcome if the method originated and published some years ago is adhered to. In rare instances it will be found that the patient develops a more or less severe diarrhea, probably due to an alkalosis. This can be overcome by discontinuing the soda in the solution and giving hydrochloric acid by mouth. The method previously published will be emphasized by repetition.

STANDING ORDERS

Before operation the patient's colon is thoroughly washed night and morning to remove all fecal matter. As soon as the patient has returned to bed from operation 16 ounces of the 5 per cent glucose and 5 per cent bicarbonate solution is thrown into the bowel and the patient is left alone for four hours, when the funnel method of giving the above glucose and bicarbonate solution is started. Have the funnel in its holder raised only above the level of the patient's rectum so that the fluid will be seen to rise and fall in neck of the funnel with the patient's breathing. This is the most important part of the method. Use a small catheter to insert into the bowel and pin the sheet over the rubber tubing with a safety pin so that the drag of the five feet of rubber tubing reaching from the catheter to the funnel will not drag the catheter out of the bowel. Allow enough of the above glucose and bicarbonate solution to flow into the funnel from the drip tank until the tube of the funnel is filled. This allows for filling of the bowel and a good view of the solution so that you can see whether it is rising and falling with the patient's breathing. Allow this to go on now for twelve hours' running in enough of the solution to keep up the level in the funnel, seeing that all the time the fluid rises and falls with the patient's breathing. Then begin every four hours to sit down by the bedside and flush the bowel out with warm tap water with

the same funnel and catheter for at least fifteen minutes at a time, raising and lowering the funnel until the bowel is washed free of fecal matter and gas. (It requires a great deal of patience at times and a longer and more frequent washing to have the gas start.) Then hang up the funnel and start the solution again for another four hours. If this is properly done the patient should suffer no inconvenience and there should be no collection of fecal matter and gas in the bowel, and the patient should never complain of gas pains, and at all times the gas has a free way to discharge out of the funnel, especially as the outlet of the catheter cannot be blocked with bowel content if the fluid rises and falls with the patient's breathing. A patient absorbs more fluid this way than by any other method. The catheter need not be disturbed in the rectum for three days, thus lessening the tenderness of these parts, and the nurse should by these means be saved much lifting and worrying of the patient.

In cases of all laparotomies the patient must be in the Fowler position immediately on return to bed from the operating room for at least twenty-four hours. Be sure that the body is on a slant toward the pelvis and not, as is so usual, only from the neck up. This is in order that all fluids



Apparatus to give the Murphy Drip by the Weeks Method.

or possible infection in the abdomen shall be gravitated toward the pelvis where it is the more readily handled by the peritoneum. If there is no intra-abdominal operation or injury the drip can be given to the patient in any comfortable position.

In cases of general peritonitis this method can be kept up for days without giving the patient anything by mouth, but perhaps a moderate amount of water from time to time.

After the patient has begun to pass gas freely through the funnel and plenty of fecal matter has collected in the lower bowel, showing the peristalsis has started and is emptying the small bowel into the large bowel, and the patient has no distress on taking liquids by mouth, the drip can be discontinued. If the patient again complains of gas on the stomach with nausea stop everything by mouth and start the drip again. Continue this until all stomach distress stops, when liquids can again be given by mouth.

If the patient vomits a great deal, try first a tumbler full of water with a teaspoonful of bicarbonate dissolved therein, to be drunk all at once. This will aid in washing out the stomach. If the vomiting continues a glass of ginger ale may be tried. If it still continues, particularly if any dark particles show in the vomitus, notify the doctor at once and make preparations to wash out the stomach.

If the patient complains of pain one-eighth grain of morphine may be given hypodermically and may be repeated three or four times during the first twenty-four hours, or as otherwise ordered.

The illustration pictures the apparatus for the Weeks' Drip. For adults use a seven-inch glass funnel and one-half-inch tubing five feet long with No. 16-18 French catheter. In infants and small children use a three-inch glass funnel and four feet three-eighths-inch rubber tubing with a very small catheter. The catheter is not to be removed from the rectum until the drip is to be discontinued entirely; the long tubing allows for irrigations of the colon by lowering and raising the funnel. If care is used this irrigation can be done while the patient sleeps, without disturbance, and the gas bubbles out of the funnel.

In the course of routine one occasionally meets a case that is urgently in need of fluids immediately. In these cases if the patient has been, for any reason, unable to take and retain sufficient nourishment and fluids by mouth or rectum, a glucose solution intravenously is indicated. For this purpose we give from 500-1000 ccs. of a 5 or 10 per cent solution. In all such cases the rectal drip is continued or started if not in use before. In critical cases of definite starvation, toxemia, diffuse peritonitis, etc., the above procedure is repeated every twenty-four hours as long as needed. Warning should be sounded here in regard to giving large volumes of fluid in the blood stream if the myocardium is weak or if there are pulmonary complications which might offer great resistance to the heart. The solution must be given very clowly, 40 to 60 minutes being taken for the infusion.

There is another type of case which is often overlooked, namely, Hepatic Insufficiency, in which glucose is a specific. This condition, first studied

and described by Bevin and Fovill, is characterized by the following symptoms:

A history of lack of nourishment, icteric tinge to sclera and skin, dry tongue, acetone breath, faces apathetica, restlessness, in fact the patient often cries out, though in a semi-comatose state in the last stages. Following death in such cases the liver and muscles are practically glycogen free, and experimentally this entity has been produced and cured by the use of carbohydrates. In these cases 20 to 25 per cent solution of glucose is given continuously in the vein, care being taken to keep within the tolerance of .8 gram per kilo per hour, usually about 60 grams per hour in the average adult. By this method one can furnish as much as 5000 calories in twenty-four hours without effort on the part of the patient. To see these cases improve and their appetite develop is most gratifying. It is important to keep the temperature of the solution between 102 and 108° F.

In baby surgery and especially in dehydrated and starved cases of Congenital Pyloric Stenosis we use a 3 per cent glucose solution in drachm quantities by mouth, beginning as soon as the patient regains consciousness from the anesthesia. In critical cases we also use the same strength solution hypodermically in both axilla and groin. It is slightly irritating, but with care in the technique there is no abscess formation. Weeks' Drip is given continuously in these cases, 3 per cent soda and 3 per cent glucose, care being exercised in selecting a small funnel, small tubing and a very small catheter.

In cases of suppression of urine following nephrectomy, trauma, eclampsia, etc., the results are often just short of miraculous. Here one must use a concentrated solution of from 25 to 50 per cent and give from 300 to 600 ccs. to the average adult. The rational of this treatment is found in the fact that glucose is a strong and efficient diuretic. Normally there is from .08 to .18 per cent of glucose in the blood, and if this percentage is increased there is rapid and marked diureses, with the urine containing the usual constituents plus some sugar. Some of these cases of suppression with uremic symptoms, with anuria from 3 to 5 days, will, after a single injection, secrete 1500 ccs. or more of urine within the first twenty-four hours and rapidly go on to recovery. The hypertonic solution increases the concentration of sugar in the blood and this stimulates the kidneys to function. By osmosis the fluid is attracted from the tissues into the blood stream and thus accumulated toxins are eliminated. If the patient is dehydrated it is well to give 1000 to 1500 ccs. of hypotonic sodium chloride solution by hypodermoclysis about one hour previous to the administration of the glucose solution intravenously. Attention to the modus operandi of the efficiency of this measure will make it plain that conservatism here will not produce the results. A solution of at least 25 per cent must be used and give from 300 to 600 ccs. depending upon the strength of the patient's heart for a guide in each case.

"REACTIONS"

We seldom see a "reaction" from the intravenous use of glucose solution, but great care is exercised in the preparation of solutions and in the temperature at which they are given. We use Merck's Anhydrous Dextrose and make a 50 per cent stock solution in doubly distilled water. From this stock solution the different strength solutions are made by dilution with fresh doubly distilled water and sterilized in the Autoclave at 120° C. for twenty minutes. In boiling a solution of glucose there is a slight ionization which renders the solution faintly acid, but this has not caused alarm. However, at the suggestion of Dr. Langley Porter, we now add Fisher's Solution in proportion of 1 to 10 to overcome this possible objection. The solutions, of course, must be sterilized separately and mixed after cooling, otherwise caramel is formed. This has not been introduced in our procedure for sufficient number of cases to make a statement as to its value, but is, we believe, a very rational addition. Too much stress cannot be laid upon the importance of giving the solution at proper temperature. We always use a tubal thermometer placed in the tube about eighteen inches from the needle in the vein and the temperature is kept between 102 to 108° F. We discovered that at some of our best regulated hospitals the intravenous administration of solutions was practiced without the use of a thermometer, and the solutions under such circumstances were given too cool for fear of giving them too hot. We also use old rubber tubing, since some writers believe reactions are often due to new tubing.

We wish to emphasize the importance of following the details as outlined above if results are to be expected. It is altogether too frequent that useful methods in the treatment of disease are abused because of carelessness or indifference to the following of necessary details.

We are not unmindful of the work of Henderson and Haggard, but we believe that until we have been able definitely to work out clinically the blood chemistry as related to its acid or alkali demands more patients will be benefited than are overalkalinized.

CONCLUSIONS

Glucose and the alkalies are valuable adjuncts to the surgeon's armamentarium. Three things are vitally essential if the patients are to be tided over the period of lowered resistance:

1. Proper amount of food for the cells in usable form.
2. Proper amount of water, and
3. Proper chemical medium for the tissue cells.

If the above methods are closely adhered to there will be less frequent administration of the futile "shots" of strychnin, camphor, etc., for cardiac failure.

YOSEMITE'S CLIMATE

Although Yosemite was discovered by a member of the medical profession, there are few medical men that know the varied charms of this incomparable valley. It will be of keen interest to those professional men in whose hands lies the health of the State and who will visit Yosemite next May at the annual convention of the Medical Society of the State of California, to find Yosemite's climate, at an altitude of approximately 4000 feet, as distinctive of California as the climate of the coast. Abundant statistics about it may be given, but the best idea of it will be conveyed by an incident of the present season, wherein the human element is more evident than in plain figures.

Two representative residents of Cleveland, Ohio, came to California eager to see the Yosemite, which they had seen pictured in their school histories and geographies, but they were fearful that the trip meant a return to Ohio, insofar as weather was concerned. And they had come to California to bask in the sunshine. Nevertheless, the lure of El Capitan and Half Dome was too strong to be resisted; so they bought their tickets and started to the park, intending to poke their noses inside the "Gates of Yosemite," take one chilly look around and then scoot back to warmer climes.

The beautiful ride from El Portal to Yosemite Valley thrilled them as it thrills everybody—and they were not cold. After luncheon they went outdoors and discovered other guests preparing to ride horseback or to go sightseeing or to walk, while some sat on the veranda in the sun, knitting or reading or just resting. And still they were not cold. It seemed curious, but they forebore to ask questions and began to consider extending their stay.

Next day the sun was as warm as ever, there were other interesting things to do, they were completely comfortable. When finally they departed, the two Clevelanders had spent fifteen days in the valley and left an unsolicited testimonial telling of their pleasure in the visit. As the patent medicine advertisements say, "Original can be seen on request." But perhaps that isn't a recommendation in the eyes of professional men! Anyway——

"We never knew a mountain winter like this," the visitors confessed to someone, and therein lies the best description of "Yosemite, A Winter Resort," that could be penned by anybody. It is different. It is in California.

Is there snow? Yes, plenty of it—sometimes more. The ground was covered with three feet of fluffy, dry powder when the Clevelanders were in the valley. There was more than three feet late in January when the thermometer in the sunshine on the Sentinel Hotel veranda registered 85 degrees. It isn't a trick thermometer either. Government records show an average maximum temperature for the winter months of 54 degrees, and that is not in the sunshine. Night temperatures fall much lower, just as anywhere else in the West; but in the daylight hours, the time when everybody is out exercising and laying up strength and quieting jangled nerves, the temperatures are balmy and delightful, even for the aged and infirm.

The reason for this unusual climate is not strange or remarkable. If it were not for the fact that the unthinking public associates mountains with cold weather in winter, regardless of whether the mountains are in Switzerland or California, there would not be so much misunderstanding to overcome in attempting to introduce Yosemite at this season.

Speaking literally, not figuratively, Yosemite Valley is a hole in the ground. It is one of the most unique holes the world has ever known, with walls of stupendous height, in some places higher than the valley is broad. Wind virtually is unknown in the valley. The sun beats down all day long, until this hole in the ground becomes a veritable natural sun parlor. And here is something that usually makes everybody laugh, but scientific men say it is true, just the same. The sun is warmer, so to speak, in Yosemite than it is elsewhere, because the glacier-polished granite of the cliffs reflects the rays into the valley until the temperature is far higher than it would be without them.

Finally, the air of Yosemite is pure and dry and rare. There is none of that chilly dampness which takes the joy out of life.

A writer described a visit to Yosemite during the cold wave which made the coast shiver and long for furnace heat. He made the statement that a temperature in Yosemite 20 degrees below that in the San Joaquin Valley offered no discomfort, while the people in the "warmer" sections of the State were talking about nothing but the cold weather. His experience and statement were duplicated many times. At a snow carnival early in February, spectators stood on the crusty top of a yard of packed snow watching the races, and complained that they were too warm wearing the topcoats to which they were accustomed in the cities.

To say more about the climate would be mere repetition with only a change of details. It should be added here, however, that any winter climate demands good food and a good place to sleep after the exertions of the day. Visitors have no cause to complain on either score.

Yosemite is open and accessible by way of Merced and El Portal every day in the year.

CAMP CURRY'S ATTRACTIONS

Spring—and in Yosemite! Do you remember how the crimson maple buds began to unfold, back East in the spring, after the snow was gone? And when the first violets emerged from the green of their leaves, and the moist brown pine needle carpet of the woods? Do you know the "feel" of the air, when the sun has driven winter away and life begins to creep upward with the green sap? Take a week and learn what it can mean, or summon it back from the limbo of your memory. Breathe air that has the tang of mountain nights and days.

The Yosemite Valley was still a good deal of a wilderness when Camp Curry's site was chosen, over twenty years ago. Yosemite Village, to be sure, was very much the same collection of frame structures that it is now, many of them dating back to the seventies or eighties. But with all the valley to choose from, this spot in the heart of Yosemite, set about with pines and firs and cedars of noble growth, between the river in one of its green and tranquil moods and the sheer granite wall of Glacier Point, took the eyes and hearts of the beholders.

Have you ever lived the free and easy out-of-door life that Camp Curry offers you? A life that puts ostentation into the discard and becomes simple and healthful and care-free? Yet there is comfort everywhere—in the bungalows, fitting harmoniously into the forest background; in the tents set in clusters among the trees, hedged about by dogwood and azalea and wild lilac in never-ending succession of flowering loveliness; in the central buildings, with their boulder-set fireplaces.

The bungalows afford living quarters unexcelled on the floor of the valley. There are wide porches from which to watch the shifting beauties of sun and shadow among the trees and along the cliffs, rooms whose walls are half windows, comfortable beds, and the most modern of sanitary appointments. The bungalows and some of the tents are equipped with electric heaters, and there is electric lighting throughout the camp.

Camp Curry's tents offer the accommodations of the usual hotel room without bath attached. Twin or double beds, a board floor with grass rug, washstand and dresser of adequate size, are the princi-

pal furnitnre. As in the bungalows there is electric lighting, and the beds are a point of pride with Camp Curry for comfort.

The central plant consists of an auditorium and dance hall with an excellent floor of hard maple, club rooms with bowling and pool, a main office and writing room, postoffice, telegraph, a delightful sunny studio with a splendid collection of photographs, in part the work of George Fiske, a pioneer photographer who lived in Yosemite for forty years and caught its reflections as no other has done, and in part the work of Camp Curry's own photographers. The dining room is comfortably warmed by steam heat and has a capacity of 800. The laundry is an attractive building, in the same unit with bathhouse and a swimming pool where Duke Kahanamoku, George Freith and other champions have met. The storage garage and a storehouse, which will make possible greater efficiency and better service for Camp Curry's guests, are the most recent additions to the main plant.

So much for physical comfort and convenience. But Camp Curry is more than a hotel or camp; it is an institution, a California institution that has taught scores of thousands the joys of outdoor life, and that comfort and camping can go hand in hand. The one great factor to this end has been the spirit of hospitality prevalent from the beginning, under the personal management of its owners. You will find here people who are thoroughly familiar with what the valley has to offer and eager to make your outing one that will linger long in your mind. Courteous and intelligent service ungrudgingly given by young college people is an important item.

The campfire is the symbol of this intimate and cordial welcome. Beside it the informal program is given nightly, brought to a close that is always beautiful and impressive by the firefall from Glacier Point. The dance follows for those who will; for others, the circle narrows around the campfire in friendly talk, or there may be a moving picture from Camp Curry's fine collection, with hints of what to see and how to see it, and glimpses of beauties that lie beyond this gateway to the Sierras.

This is the year of years for Yosemite. All winter long the snows have been piling up in great masses, drifting under the trees, swooping down the canyon sides in avalanches, covering high mountain peaks and frozen blue lakes—for you! There will be moonlight on the swirling mists of waters, and that rare thing upon the earth, the lunar rainbow, circling the Yosemite Falls. The sun will pierce with brilliant light the rockets of Nevada and play a merry game of kaleidoscopic colors in the wind-blown spray below Vernal; and throughout the course of the valley and on down the rocky canyon the Merced will beat and snap and foam about the debris of centuries.

THE ST. LOUIS MEETING OF THE AMERICAN MEDICAL ASSOCIATION

The May meeting of the American Medical Association at St. Louis promises well toward being the largest in attendance of any of the Association's sessions. Since the publication of the hotels in the Journal of the Association in December, inquiries and reservations are being made daily. The hotels and the Conventions Bureau are aiding the Committee in a most satisfactory and helpful way to see that the Fellows are comfortably housed and accommodated. The A. M. A. meetings tax all cities entertaining them to the limit of hotel capacity. Whenever possible a good Fellow should double up so that no one is left without comfortable lodging.

Reservations should be made by communicating direct with the hotels. If satisfactory arrangements cannot be made in this way, write to Dr. Louis H. Behrens, Chairman Committee on Hotels, 3525 Pine Street, St. Louis, Mo.

COUNTY SOCIETIES

Alameda County Medical Association (reported by C. L. McVey, secretary)—A meeting was held on the 16th of January at the Public Health Center. Clarence DePuy, M. D., was in charge of the meeting, introducing W. A. Wood, who read a paper upon "Abnormal Conditions Found in the New-Born." E. Spense DePuy demonstrated X-ray plates of a tuberculous kidney. E. N. Ewer's paper was "Radium Treatment of Uterine Fibroids." These papers were discussed by Sargent, Adams and Jelte.

Miss Florence Atkinson, secretary of the California Association of Physiotherapists, spoke upon the work which the trained physiotherapists are attempting in the treatment of cases upon the prescription and under the supervision of physicians.

George W. Crile of Cleveland, Ohio, was the speaker at the annual banquet of the society, at the Hotel Oakland on February 15.

At the January meeting of the Merritt Hospital Staff Council, A. M. Smith reviewed the literature of arthritis deformans. The frequent association of achylia gastrica with this type of arthritis was noted. C. A. Dukes presented a new type of apparatus for the fixation of certain types of compound fractures. Officers elected for the year 1922 were: President, George Rothganger; vice-president, A. M. Smith; secretary, Robert Glenn.

Butte County Society (reported by J. O. Chiapella, secretary)—At the annual meeting of the society held in January, the following officers were elected for the ensuing year: President, Joseph P. Schell; vice-president, Thomas B. Reardon; secretary-treasurer, J. O. Chiapella; censors, P. L. Hamilton, J. P. Schell, W. E. Poole; program committee, Schell and Chiapella.

Contra Costa County Medical Society (reported by L. St. John Hely, M. D., Secretary)—The January meeting was held in the offices of Drs. Cunningham and Carpenter at Richmond. Routine matters were attended to at the meeting, and E. R. Guinan, M. D., 1002 Macdonald avenue, Richmond, was elected to membership.

Fresno County Medical Society (reported by Thomas F. Madden, secretary)—The February meeting was held at the commercial club on February 7, 1922. Those present were: President G. W. Walker, Madden, Kjaerbye, Schiro, Sheldon, Tupper, Anderson, Cross, Weise, Staniford, Broemser, Barrett, Tillman, Trowbridge, Sciaroni, McConnell, Willson, Couey, Miller, McPheeters, Stein, Aller and Montgomery.

Paul Campichi of San Francisco presented the subject of "Goiter, Classification and Treatment." Tupper, Cross and Anderson took part in the discussion.

Marin County Medical Society (reported by Chester A. DeLancey, M. D., secretary)—The annual meeting and banquet was held at Pastori's on January 21, and the following officers were elected and installed for the coming year: President, J. H. Kuser, M. D.; vice-president, L. L. Stanley, M. D.; secretary, Chester A. DeLancey, M. D.; delegate to State Meeting, A. H. Mays, M. D.; alternates, H. O. Howitt, M. D., and H. O. Hund, M. D.; trustees, Doctors Kuser, Howitt and Hund.

The evening was spent in discussing the "Political Situation as it Affects the Medical Profession and Marin County in Particular."

W. F. Jones, M. D., member of our society, is a candidate for the Assembly for Marin County.

Mendocino County Medical Society (reported by Paul J. Bowman, secretary)—The annual meeting of the society was held at Fort Bragg on the 8th of February. The following officers were elected: President, Lew K. Van Allen; vice-president, F. McLean Campbell; secretary-treasurer, Paul J. Bowman.

Hans Lisser, M. D., of San Francisco, discussed the subject of toxic and non-toxic goitre.

Merced County Medical Society (reported by Brett Davis, M. D., secretary)—The February meeting was held on the 2nd in the offices of the secretary. A. C. Reed of the extension service of the State Society was present and presented the subject of "Heart Disease in Every Day Practice."

The directors of the Mercy Hospital Association of Merced have secured a site and the payments for stock subscribed are about half completed. The directors expect to select an architect shortly and prepare to build the hospital in the spring.

San Bernardino County Medical Society (reported by E. J. Eytinge, M. D., secretary)—The February meeting was held Tuesday, February 7, with thirty members and ten visitors present and forty members absent.

"The Clinical Significance of the Basal Metabolic Rate Determination" was presented by Nelson W. Janney, M. D., of Los Angeles. The entire evening was spent in the discussion of endocrine and metabolic diseases, led by Dr. Janney.

Floyd Wm. Gardner of Loma Linda was elected to membership.

Sacramento County Society (reported by Dr. G. J. Hall, secretary)—The annual meeting of the Sacramento Society for Medical Improvement was held on Tuesday, December 20, and a special meeting of the Board of Directors was held on January 4. An amendment to the constitution and by-laws was passed and made effective.

The following officers were elected for the coming year: President, Dr. G. P. Dillon; Dr. B. F. Howard, vice-president, and Dr. G. J. Hall was re-elected secretary. The following directors were elected: Dr. Schoff, Howard, Dillon, Foster, Pope and Henderson. Delegates to the State society meeting: E. C. Turner and E. T. Sullivan Jr.; Dr. S. E. Simmons was re-elected a member of the Executive Committee.

The annual dues of the society were increased from $12 a year to $15, in order to pay the expenses of the secretary to all State medical meetings.

San Diego County Medical Society (reported by Robert Pollock, M. D.)—The San Diego County Medical Society has again outgrown its quarters and has accepted the invitation of Mr. C. S. Holzwasser to meet in the auditorium on the eighth floor of his new store building, at Fifth street and Broadway. Such meetings as are not of a clinical nature will hereafter be held at this place. Clinical programs will continue to be furnished at St. Joseph's and the County General Hospital.

A joint meeting of the Medical Society and the Medical Staff of St. Joseph's Hospital was held at the hospital auditorium Tuesday evening, January 24. P. M. Carrington gave an interesting résumé of the work of the League for the Conservation of Public Health and urged the support of the profession. Interesting reports of cases of "Meningeal Irritation in Influenza and Simulating Meningitis" were given by C. L. Stealy. A paper on the "Diagnostic Limits of the X-ray" was read by W. O. Weiskotten and discussed by Dr. Churchill.

Bobbitt, of the navy, reported a case of multiple tumors of the cerebellum, which was discussed at some length by Little, Hummel, Thompson, Oatman and Burger.

Dr. O. G. Wicherski has just organized the med-

ical staff of the San Diego County General Hospital for 1922. Three principal groups of service are recognized—General Medicine, Surgery and Laboratories. Each is organized with a chief of clinics and section officers.

San Francisco County Medical Society Meeting of January 10 (reported by L. H. Briggs, M. D., Secretary)—The entire meeting with about 150 members present was devoted to a discussion of the various phases of the diphtheria problem. Charles Fleischner spoke extemporaneously on the importance of the subject from the standpoints of contagiousness, treatment, and of epidemiology.

Wm. C. Hassler, M. D., presented a paper on the work of the Municipal Department of Health in the control of diphtheria. Hassler's conclusions are:

"1. Don't wait for a laboratory diagnosis when the case is clinically one of diphtheria. The laboratory test may be negative because of no growth and except in doubtful cases, is only confirmative if possible.

"2. Administer a large dose at once, of antitoxin preferably into the vein, next into the muscle, but never just under the skin.

"Frequently physicians inquire what should be the dose of antitoxin. This has been settled fairly well by Schick, who advises the administration of 100 units for approximately each 2 1 5 pounds of body weight and 500 units for the same weight in the very severe and late cases. Administer the antitoxin preferably into the vein, next into the muscle, but never just under the skin.

"3. As a procedure of safety, before giving antitoxin, question as to previous doses at any prior illness or as to being afflicted with asthma, urticaria, and always examine the heart. In cases that give a history of urticaria the patient should be desensitized by giving first a half cc. of antitoxin under the skin, and one hour thereafter half cc. of antitoxin into the muscle, and then repeat this process, doubling the dose every hour until the required amount of antitoxin is administered necessary for the status of the case. In cases where heart complications exist, intravenous medication is contra-indicated.

"4. Treat the disease as serious to the life not only of the patient, but of all contacts and the community.

"5. Suspect every child with temperature, sore throat, or running nose, and even a slight degree of aphonia, as being a case of diphtheria until the laboratory has decided otherwise."

W. H. Kellogg, M. D., director of the Bureau of Communicable Diseases, State Board of Health, presented a paper on the "Prevention of Diphtheria." Among other points Kellogg emphasized the public health responsibility of physicians when called to treat patients suffering from diphtheria.

"1. He should realize that cases of apparently simple sore throat may be diphtheria and should always take a swab.

"2. If the case shows any toxic symptoms, or is at all suspicious of diphtheria, he should never wait for the laboratory report before giving antitoxin, particularly if the examination is made at a State laboratory when the delays of the mail are serious.

"3. Having determined to give antitoxin, as many units should be given at one dose as will be required for the cure of the case as near as it can be estimated; the idea being to give at the first dose enough antitoxin to neutralize all of the toxin that is free in the circulation, as well as all that will be produced in the next three or four days.

"4. He should passively immunize other members of the family according to circumstances, as follows: If he is dealing with intelligent people and is in close touch with the family, he may apply the Schick test to the other children, awaiting the result and giving an immunizing dose of antitoxin to those found Schick positive. If for any reason delay could result between the development of a second case and his immediate notification thereof, he should give antitoxin to all the contacts. When antitoxin is used in this manner the physician should never forget that passive immunity does not prevent the carrier state and that the protection disappears in two or three weeks, at which time any carrier may become infected. This frequently results in a second death in the family, the people believing that the second case is not diphtheria, owing to the previous immunization, and therefore fail to call the doctor promptly. Active immunication by toxin-antitoxin is not applicable to the protection of persons recently exposed, as the immunity following is of slow development.

"5. The physician should instruct the family in the importance of strict isolation of the case from the rest of the family. Where possible, the attendant of the sick child should not associate with the well children, as she is almost sure to become a carrier. They should be instructed to collect and burn all secretions from mucus membranes of the patient, to keep separate, clothing, bedding and eating utensils.

"6. Finally, he should preach continually among his patients, the active immunization of children against diphtheria."

No notice of the other papers presented at this program are given because neither paper nor abstract has been submitted to the editor.

There was a meeting of the Committee on Industrial Medicine on January 17, for a discussion of the free choice of physicians in industrial accident cases and discussion of the fee schedule. The principal speakers were W. H. Pillsbury, attorney for the Industrial Accident Commission; Morton Gibbons, Gayle G. Moseley, James Eaves and G. W. Goodale.

The Committee on Eye, Ear, Nose and Throat met on the 24th of January. Abstract of the proceedings has not been received.

The Committee on Urology met on January 31. The only abstract received was of the paper presented by M. B. Wesson, M. D., on "Studies of Trigonal Area of the Bladder." The author called attention to a compensatory hypertrophy of the trigon in cases of obstruction at the vesical orifice due to overexercise of the trigonal muscle in opening the vesical orifice. A corresponding atrophy follows the removal of the obstruction (prostatic hypertrophy or median bar). The trigon may be dissected from the bladder wall in cases of tuberculosis and have to be removed with a resultant incomplete and difficult micturition; with removal of one-half of the trigon the remaining half functions and the bladder can be entirely emptied. The same is true when the trigon is split; however, a split trigon is not functionally as perfect as one with Mercier's bar intact.

The obstruction due to a hypertrophied trigon can be removed: (1) Intra-urethrally, by means of a punch or a trigonotome; (2) perineally, by means of a scalpel or trigonotome; (3) suprapubically, by means of a scalpel and scissors. The latter method is the operation of choice, since hemorrhage can be controlled.

With the removal of all vesical obstructions and the preservation of a maximal amount of the trigon, the untoward symptoms disappear and practically perfect function is restored.

San Joaquin County Medical Society (reported by Dewey R. Powell, M. D., Secretary)—The regular meeting of the San Joaquin County Medical Society was held Friday evening, January 13, at the State Hospital. Those present were: Hudson Smythe, president; Minerva Goodman, Grace McCoskey, J. G. Vischi, B. F. Walker, H. E. Sanderson, E. A. Arthur, F. J. O'Donnell, J. J. Tully, L. R. Johnson, C. F. English, B. J. Powell, H. E. Price, R. T. McGurk, L. Haight, J. P. Hull, Margaret Smythe, F. P. Clark, H. S. Chapman, W. P. Lynch, W. T. McNeil, R. R. Hammond, A. H. McLeish, C. R. Harry, F. J. Conzelman, J. T. Davison, E. L. Blackmun, Hudson Smythe and D. R. Powell, with H. L. Gregory of Stockton, Captain Day of the Army Medical Corps, Stanley Stillman and Walter Scott Franklin of San Francisco as guests of the evening.

The first speaker of the evening was Walter Scott Franklin, M. D., Professor of Ophthalmology at the University of California, who spoke on "Strabismus." The speaker emphasized particularly the fallacy of the adviee formerly given by the family physician to wait in these cases before instituting treatment; that they would outgrow it or else there would be time enough to attend to it when the child should grow older. He spoke of the excellent results that could frequently be achieved by taking the child just as soon as the danger was in any way noticed, the important thing being the preservation of the vision, which otherwise would be impaired from disuse if the eye were not corrected early. He spoke particularly of the advantage of covering the good eye and foreing the weaker eye to do the work, and in that way educate the weak muscles. Franklin concluded his remarks by reiterating the importance of attending to strabismus eases early in young children. The paper was discussed briefly by B. F. Walker, B. J. and D. R. Powell.

The next speaker of the evening was Stanley Stillman, Professor of Surgery at the University of California, who spoke on "Difficulties of Gall Bladder Surgery." He mentioned first the cases of acute cholecystitis and the question that always arose as to whether to treat the case medically or surgically. In his experience a number of cases had gone along very nicely without operation and it was advised when the acute symptoms seem to be subsiding to defer surgical procedure, but if the symptoms progressed to operate at once. He spoke of the inefficiency of the X-ray as aiding in diagnosing gall bladder conditions and cited several instances where the X-ray was positively misleading. He mentioned the danger of operating in cases of gall bladder in suspected focal infection and cited that in a number of apparently normal gall bladders there were oftentimes severe postoperative eonditions. He spoke of the old question of drainage and stated that he felt safer in eases of severe infection to have a drain, particularly where there was distinct hepatitis in association with the gall bladder trouble.

The members present discussed the paper and Stillman very courteously answered a number of questions. The president thanked the visitors on behalf of the society for their courtesy in presenting such splendid papers.

Santa Barbara County Medical Society (reported by Alex. C. Soper, Jr., M. D., Secretary)—The annual meeting and banquet was held January 9. Walter V. Brem, M. D., Wm. T. McArthur, M. D. of Los Angeles, and E. S. Kilgore, M. D. of San Francisco, all presented papers before the society.

The following offieers were elected for 1922: President, William J. Mellinger, M. D., Santa Barbara; vice-president, Harry L. Schurmeier, M. D., Santa Barbara; first vice-president-at-large, J. C. Cummings, M. D., Carpinteria; second vice-president-at-large, Wm. T. Lucas, M. D., Santa Maria; secretary-treasurer, Alex. C. Soper, Jr., M. D., Santa Barbara.

At the meeting of January 23, Charles Stivers, M. D., of Los Angeles, discussed "Speech Defects" with presentation of cases. Horace F. Pierce reported a patient suffering from Primary Splenomegaly.

Construction has been started upon the new children's wing of the Cottage Hospital. This is to cost $50,000 and is the gift of Mrs. William H. Bliss.

The St. Francis Hospital is out on a campaign for funds to build their new hospital.

There is a barber shop in the San Marcos Building at Santa Barbara that sterilizes every hair brush after it is used.

Santa Clara County Medical Society (reported by E. P. Cook, M. D., Secretary)—The January meeting of the society was held at O'Connor Sanitarium on the 18th. Thirty-eight members were present, including four from Gilroy and three from Palo Alto; seventy-two were absent.

J. L. Pritchard, M. D., discussed the new hospital records and staff rules of O'Connor Sanitarium. He stated that a new record room had been prepared and that hereafter O'Connor Sanitarium will keep and index records. O'Connor Sanitarium is also installing a Sanborn apparatus for the determination of basal metabolism.

A. J. Baiocchi, M. D., reported a case of carcinoma of the stomach in a woman thirty-one years of age. The case was interesting from the standpoint of diagnosis with particular reference to carcinoma and syphilis. Exploratory operation was refused and the patient reacted unfavorably to salvarsan. Subsequently an exploratory operation was performed and carcinoma was found.

M. D. Baker, M. D., read a paper on the various conditions affecting the pelvis. J. H. Shepard, M. D., demonstrated basal metabolism methods and discussed the value of basal metabolism determination in various thyroid conditions.

New members elected are: Alson A. Shufelt, M. D., graduate of the University of California Medical School, 1917, office Bank of Italy Building, San Jose; practice limited to Obstetrics and Gynecology. Donald G. Davy, M. D., graduate of the Stanford University Medical School, 1920; resident physician and surgeon of the Santa Clara County Hospital at San Jose. Charles L. Ianne, M. D., graduate of the College of Medical Evangelists, Los Angeles, 1921; intern at Santa Clara County Hospital, San Jose. W. L. McWhirter, M. D., graduate of the University of Texas, 1917, was elected to associate membership in the County Medical Society; Dr. McWhirter is the resident pathologist at O'Connor Sanitarium and is a member of the Texas State Medical Society.

The final plans for the new San Jose Hospital have been aceepted and specifications are now being completed by the architects.

Solano County Medical Society (reported by A. V. Doran, secretary)—The February meeting was held on the 14th at the Vallejo General Hospital, with eight members present and nine absent. The following officers were elected for the ensuing year: President E. B. Todd; vice-president, R. E. Allen; secretary-treasurer, A. V. Doran.

The Vallejo General Hospital is nearing completion. The county is at present without any faeilities for isolation or treatment of communicable diseases.

Sonoma County Medical Society (reported by N. Juell, M. D., Secretary)—The January meeting was held in Dr. Fisher's office at Santa Rosa with eight members and three visitors present.

G. W. Pierce, M. D., discussed plastic surgery and, after the dinner which was part of the program, there was a general discussion of social medicine.

Yolo County Medical Society (reported by Lela J. Beebe, M. D., Secretary)—The December meeting was held at Woodland on the 13th with the following members present: W. E. Bates, L. J. Beebe, W. J. Blevins, M. B. Bransford, C. H. Fairchild, F. R. Fairchild, J. L. C. Goffin, H. R. King, J. P. McManus, F. L. Newton, C. A. Poage, M. W. Ward.

The scientific program of the evening consisted of a "Demonstration of Metabolism Methods," by L. J. Beebe, M. D.; "Diagnosis of Hypo and Hyperthyroidism," by W. E. Bates, M. D.; "Surgical Treatment of Thyroid Disorders," by F. R. Fairchild, M. D.; "X-ray Treatment of Thyroid Disorders," by H. D. Lawhead, M. D., and "Medical Treatment of Thyroid Disorders," by C. A. Poage, M. D. The speakers were limited to ten minutes; the meeting was a very interesting one and discussion was quite general.

Keith of Williams and John Lawson of Woodland are to be voted on for election to membership at the next meeting of the society. Salter of Williams, Floreth of Dixon, Thompson of Winters and Rathbun of Colusa, are licensed physicians of Yolo County who are not members.

Yolo County would like to see more papers in the Journal devoted to physiotherapy and more suggestions on how to get health education over to the smaller communities.

Chiropractor Hollenbeck of Woodland has been arrested for practicing medicine without a license.

The Woodland Sanitarium is enlarging its physiotherapy department and is making various improvements, such as a high frequency coil, deep therapy lamp and a quartz mercury lamp, and is building seven new treatment rooms.

The position of County Health Officer became vacant with the death of C. E. Beebe, M. D., and H. D. Lawhead, M. D., has been appointed to the position.

The Woodland Sanitarium is now holding three health conferences a week; one for infants and preschool children, one for school children and one for mixed group patients.

Is there any ruling covering persons doing massage and electrotherapy, but not advertising themselves as physicians? How far may they go? Must they work only under a physician's prescription, or are they privileged to treat by these means those who come to them without being referred by a physician, so long as they do not claim medical skill or training?

[Note: The answers to these questions are found in the Preamble and Constitution of the California Association of Physiotherapists, published in the July number of the Journal and in an editorial in the same number on the same subject. Members of this association practice physiotherapy only under the supervision of the physicians in certain matters and carry out the physicians' written prescriptions in other matters.—Editor.]

Extension Work—The advertisement of the San Francisco Polyclinic and Post Graduate School appears on page 4 of this issue. Outlined courses of this character given by competent organizations reflect an important phase of extension work and clinical instruction of great value to the profession and to the public. It is hoped that other efforts will be made by hospitals and medical schools to give graduate instruction in a variety of fields.

BOOKS RECEIVED

Lessons on Tuberculosis and Consumption, by Charles E. Atkinson, M. D. 12 mo., Cloth, 470 pages. Price, $2.50 net. Funk & Wagnalls Company, New York, Publishers.

South America from a Surgeon's Point of View, by Franklin H. Martin, C. M. G., M. D., F. A. C. S. Fleming H. Revell Company, Publishers, 158 Fifth Avenue, New York City.

The Surgical Clinics of North America (Issued serially, one number every other month), Volume I, Number 5 (The Mayo Clinic Number), 296 pages, with 163 illustrations. Preclinic year (February, 1921, to December, 1921). Paper, $12 net; Cloth, $16 net. Philadelphia and London: W. B. Saunders Company.

About Book Reviews—"The average medical book review is a perfunctory insult to the intelligence of the journal's audience, and taken by and large is worthless, even from the viewpoint of bookselling, which undoubtedly does exercise a certain influence upon its creation.

"Relatively few people can write a good medical review of any sort, only an expert can write an accurate critical analysis and appraisement of a book treating of a special subject. It requires knowledge and experience to make a judgment of the value of a given book and the book reviewer must in addition be able to give clearcut expression to his criticism. A great many medical books scarcely deserve space in the Books Reviewed columns and should be ignored. Mischievous misleading books should be mercilessly attacked. Strong useful books should be subjected to constructive, stimulating criticism.

"One such able, honest, independent review a month will do a medical journal and its readers more good than a hundred half-baked, stock-form reviews which are equally valueless to author, reader and publisher."—(Abstracted from Editorial, N. Y. Med. Jour., January 18, 1922.)

This editorial and the one in our own Journal outline the policy that the California State Journal of Medicine hopes to follow in the future.

NEW MEMBERS

Edw. J. Ghidella, San Francisco; George V. Alderson, Chino; David C. Mock, Redlands; William L. Vickers, San Bernardino; Vernon C. Charleston, Needles; W. W. Cress, Sacramento; Smith McMullin, Folsom; Henry D. Buckman, Sacramento; Charles B. Bennett, Berkeley; Philip H. Petch, Oakland, Cal.; Dalton G. Paxman, Oakland, Cal.; Fred J. Walter, San Diego; G. W. Blatherwick, R. I. Hubert, Joseph A. Conaty, Jr., Verne R. Mason, Los Angeles; William L. Renick, Long Beach, Cal.; Henry D. Eaton, Los Angeles; Rowland P. Stanley, El Monte; C. Max Anderson, Hermosa Beach; Edward N. McKee, Los Angeles; Clifford A. Wright, Los Angeles; Poul M. Hunter, Pasadena; J. J. Gaynor, Davenport; Robert B. Hoag, Boulder Creek; W. Grant Hatch, Santa Cruz; William F. Stein, Fresno; John A. Montgomery, Fresno; Adolph Rosenthal, Ralph Rabinowitz, Albert H. Moore, Joseph Fife, George H. Becker, Harold J. Cooper, Elizabeth Schulze, Jesse W. Citron, Albert M. Jacobs, San Francisco; Zach Coblentz, Santa Maria.

Resigned—C. F. McCarthy, San Francisco.

MISCELLANEOUS

ADDITIONS TO EXTENSION LECTURES

For other lectures, see November and February numbers of the Journal.

HAROLD W. WRIGHT,
Flood Building, San Francisco.

I—The Psychoses of the Puerperal State:
Toxic-exhaustive syndromes and manic-depressive syndromes; differential diagnosis; factors influencing prognosis and course of disorder and liability to recurrence. Case reports illustrative of the above.

II—The Insanity of Adolescence: (Dementia Praecox)
Historical survey; premonitory symptoms; clinical types; differential diagnosis.

III—The Prognosis in Various Mental Diseases:
Toxic; organic; functional; traumatic; developmental. The type of original personality in relation to prognosis. The need of observation facilities in general hospitals prior to decision as to commitments as a humane and an economic measure.

The Ernest H. Baynes Lecture on "The Truth About Vivisection"—On page 73 of the February number of the Journal announcement is made of the 1922 popular medical lectures given by Stanford University at Lane Hall. All of these lectures are very much worth while to members of the medical profession and to the public. Mr. Baynes' lecture is of particular interest and of the very greatest importance to every citizen of the State, because this matter is making its usual perennial appearance before the voters of California. It is hoped that as many people as possible will attend this particular lecture, the date being Friday, March 10, 1922.

Private Lectures in Ophthalmology—A group of ophthalmologists of San Francisco are making arrangements to have Professor Fuchs of Vienna give a private course of lectures to ophthalmologists during his visit here as the guest of the California Academy of Medicine in June. Invitation is extended to members of the State Society throughout the State to avail themselves of this opportunity. Any wishing to take this course should write to Dr. Harold A. Fletcher, 804 Butler Building, San Francisco, for particulars.

Socialized Medicine—"That there are influences in this country which are bent on bringing all the people's affairs under official scrutiny, is most apparent from the efforts now being made to create a sentiment in favor of 'State medicine.' This means simply: more jobs, no privacy, curtailment of freedom, the destruction of the medical profession by the discouragement of research work, and the coarsening of delicate intimacies. It means practically that what the United States Shipping Board did to the shipping situation of the country, 'State medicine' would be permitted to do to the people's health.

"Between family physicians and families there is a confidential relation which rests on choice and experience. It is not official. It is not altogether professional. It partakes of the confessional in large degree, and constitutes a friendly pact based on the experience of many fights with disease and death. So well recognized is this that the family physician has become a fixed figure in our lives, and with results of undoubted good, as the records generally show.

"To change all this and establish a police health station, as it were, at which citizens must apply for medical aid and await the pleasure of an official doctor who is paid anyway, and whose professional career does not depend on the confidence he is able to evoke by skilled and loyal service, is to suggest something which is so alien to our Americanism as almost to prove an alien course and an alien purpose."—(Editorial from Dearborn Independent.)

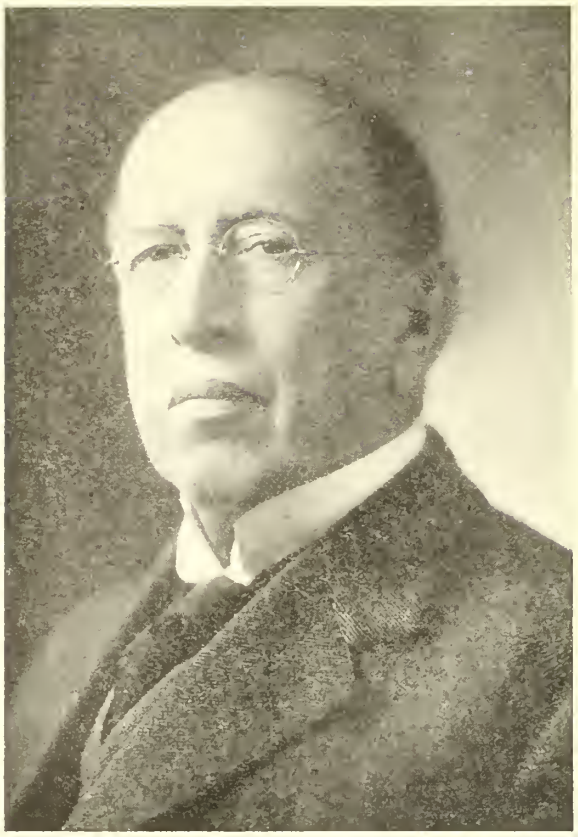
Vacancies in the Regular Corps of the U. S. Public Health Service—Examinations of candidates for entrance into the Regular Corps of the U. S. Public Health Service will be held at the following named place on the date specified: At San Francisco, Calif., March 13, 1922. Candidates must not be less than twenty-three years nor more than thirty-two, and they must have been graduated in medicine at some reputable medical college, and have had one year's hospital experience or two years in professional practice. They must pass satisfactorily oral, written, and clinical tests before a board of medical officers. Successful candidates will be recommended for appointment by the President with the advice and consent of the Senate. Requests for information or permission to take this examination should be addressed to the Surgeon General, U. S. Public Health Service, Washington, D. C.

Physical Standards for Children—According to the United States Public Health Service, "The common test of a child's health development, and about the only test that can readily be applied to children in mass, is to ascertain by some standard table of age-weights prepared for the purpose, whether or not they weigh as much as they should at their age. If the child is 10 per cent or more under standard, it is considered to be under-nourished and is treated accordingly.

"This, however, may or may not be the case, for the standard tables are largely approximations. Nevertheless, they serve a useful purpose, pending the establishment of more accurate and scientific standards, by calling attention to individual children and causing a more careful examination to determine whether the sub-standard weight is due to a remediable cause.

"Some of the age-weight standards used in the United States are merely averages of all classes of children, including with the well those who have hampering physical defects and those who are actually under-nourished. They probably never did apply to all parts of the United States, and quite possibly they no longer apply even to the particular part for which they were originally devised."

This quotation from the U. S. Public Health Service expresses mildly and conservatively a problem that is being daily amplified by the enthusiasm of statistical standardization experts. Inquiries from physicians from all over the State and from intelligent citizens show that the so-called standards are being interpreted too literally and not always by competent observers. We have the definite assurance of pediatricians of uncommon ability that some of the finest, healthiest specimens of children in the State of California are pronounced "under-standard" or "under-nourished," and parents and friends are made anxious over an ever-increasing number of perfectly healthy children.



WALTER LINDLEY, M. D.

AN APPRECIATION OF WALTER LINDLEY

By H. G. BRAINERD, M. D.

It was my good fortune to make the acquaintance of Dr. Walter Lindley in 1886. At that time he had been in Los Angeles about ten years, and had built up a large medical practice, but had taken time to infuse new life and activity into the moribund Los Angeles Medical Society, and was its efficient secretary and later president.

He had improved the sanitary condition of the city by his service as health officer, and had served on the Board of Education: had devoted much time in helping start the Los Angeles Orphans' Home, and for a number of years was physician to the Home, and president of its Board of Managers. He had, also, been superintendent of the Los Angeles County Hospital for a couple of years.

At the time I became acquainted with him he was devoting his energies to organizing the first medical college in Los Angeles, and for several years thereafter was its efficient secretary, and later secretary and Dean of the Faculty.

His work in connection with the Board of Education and Orphans' Home led him to take great interest in defective children, and it was largely through his efforts that the Whittier State School was established. When it was finished and equipped he was its superintendent for the first five years of its existence, and later continued on its Board of Trustees. After resigning the superintendency of the Whittier State School he returned to Los Angeles and one of his first activities was to organize the California Hospital, to which he devoted largely of his time and means. He was its efficient medical director until it passed last year into the hands of the California Lutheran Hospital.

Shortly after the opening of the California Hospital he established a training school for nurses, the first to be established in Southern California. About this time he became publisher of the Southern California Practitioner, and was for many years the editor and publisher.

Prior to his superintendency of the Whittier State School he had become a member of the National Association of Charities and Correction, and for several years served as its secretary and later vice-president.

With all of his many interests he always found time to devote to the political affairs and the social welfare activities of the city.

He once said to me that the height of his ambition in the matter of wealth was to be able to buy all the books he wanted, and throughout his life he was always collecting choice books until he had a very large and valuable library, which was a source of great pleasure to himself and many of his friends.

He always gave a hearty welcome to the new physicians in Southern California, and scores of young doctors have been greatly indebted to him for his encouragement and help. No friend ever went to him with his troubles without receiving sympathy.

The apoplectic stroke, which came to him while at work, proved fatal in a few hours.

He has left to his sons and daughters a wonderful heritage of an unsullied life full of good works, and to his friends a memory of a beautiful friendship.

DEATHS

Hickman, W. S. Died in Georgetown, California, January 9, 1922. Was a graduate of Medical Department Vanderbilt University, Tenn., 1886. Licensed in California, 1886. Age 65.

McCoy, John. Died in the Soldiers' Home, Sawtelle, Calif., December 21, 1921. Was a graduate of Medical Department of the University of Michigan, March 30 1865. Licensed in California, 1890.

Felton, Lucius Ely. Died in Hanford, Calif., January 8, 1922. Was 72 years of age and a graduate of Bellevue Hospital Medical College, New York, 1871. Licensed in California, 1891.

Clifford, John Bruce. Died in Santa Barbara, Calif., January 12, 1922. Was a graduate of the California Medical College, California, 1894. Licensed in 1894.

Felton, Lucius Ely. Died in Hanford, Calif., January 8, 1922. Age 72. Was a graduate from Bellevue Hospital Medical College, New York, 1871. Licensed in California, 1891.

Gilliland, A. B. Died in Cottonwood, Calif., January 26, 1922. Was a graduate of the U. S. Grant University, Tennessee, 1894, and licensed in California, 1897. Was president of the Shasta County Medical Society of the State of California.

Johnson, J. H. Died in San Gabriel, January 16, 1922. Was a graduate from University City of New York, 1887. Licensed in California, 1888. Was a member of the Medical Society, State of California.

Layman, D. W. Died in San Diego, January 15, 1922. Was a graduate of the University of Illinois, College of Physicians and Surgeons, 1904. Licensed in California, 1921. Was a member of the Medical Society, State of California.

Lindley, Walter. Died in Los Angeles, January 24, 1922. Was a graduate of Long Island College Hospital, New York, 1875. Licensed in California, 1876. Member of the Medical Society, State of California, also State Board of Health and a former member of the State Board of Medical Examiners.

Morrissey, Joseph Grant. Died in San Francisco, January 13, 1922. Was a graduate of Medical Department, University of California, 1894. Licensed here the same year. Age 57.

Owen, Henry W. Died in Bakersfield, Calif., December, 1921. Was a graduate from College of Physicians and Surgeons, Kansas City, Mo., 1901. Licensed in California, 1901. Age 53. Was a member of the Medical Society, State of California.

CORRECTION—The Editor regrets that an error was made in the March number of the Journal in giving credit for the article on "Glucose and Alkalies in Surgery" to Alanson Weeks and LeRoy Briggs, when it should have been Alanson Weeks and LeRoy Brooks.

SUPRAPUBIC VERSUS PERINEAL PROSTATECTOMY

A Comparative Study of 134 Personal Cases

By FRANK HINMAN, A. B., M. D., F. A. C. S.
Assistant Clinical Professor of Urology, University of California, San Francisco, Calif.

Unless men who have been trained by Young can demonstrate to their own and their colleagues' satisfaction that they have acquired from him the ability to properly perform perineal prostatectomy, and can themselves train others, this operation is in a fair way to disappear. Its technical difficulties have proven too great for general adoption. Attempts to perform it were almost universal following Young's earlier publications, but the failures are so evident that men have come to prefer the greater surgical risk of suprapubic prostatectomy because of its greater assurance of cure in their hands.[1] Young himself strongly advises against an attempt of his operation by the inexperienced. These ideas have now become so general that a majority of urologists have never done perineal prostatectomy, and others only a relatively few cases. These cases, furthermore, usually have been of the small fibrous type or unusually poor clinical risks. Other perineal operations, such as the median perineal, have also been occasionally tried. Results obtained, however, have often been ascribed to the perineal method. All results, both by the inexperienced in Young's method and perineal methods other than Young's, have been used for comparison by the suprapubist, but from what has just been said of the technical experience required and the fact that we believe that no other perineal operation is as efficient as Young's, such a comparison is unjust. The inability of the majority to perform the operation does not prove to the satisfaction of those who can perform it, that the operation when properly performed is inefficient or inferior to the suprapubic method.

[1] Delbet of Paris, for example, at the French Urologic Association, 1920, reported no mortality by way of the perineum and 17 per cent suprapubically, and yet unqualifiedly declared in favor of suprapubic prostatectomy because practically all of his perineal cases had had persistent fistulae or suffered recurrence of prostatism.

The obvious, though unintentional unfairness to Young's perineal method, has been fourfold:

1. Comparison of the results of men inexperienced in performing perineal prostatectomy with results of experts by way of the suprapubic route. The only just comparison is expert with expert.

2. The general tendency of the operator, who occasionally does both operations, to subject his poor surgical and urological risks to the perineal operation, and the more typical hyperplasia of the younger good clinical cases to the suprapubic operation, because of the recognized more benign nature of the former. The very cases that are most likely to have a poor functional result by any method have in this way been subjected to the perineal operation.

3. It is well to recognize that advanced or complicated prostatism, a type most difficult of cure, is commonly accompanied by the operative risk of a poor clinical condition, such as cardiac or renal insufficiency. A suprapubist kills off these potential functional failures, but the majority survive perineal operation, and in consequence lower the percentage of complete cures. It is only fair, therefore, that operative deaths have due consideration in the comparison of the functional results of cure, improvement or failure by the two methods.

4. Attention should be drawn to the discrepancy in statistics that is apt to arise since the more general adoption of a two-stage procedure in suprapubic prostatectomy. Those cases which do not survive the first stage are not considered as fatalities of suprapubic prostatectomy, but in our limited experience and as generally stated as that of others with a wide experience, those that do survive have weathered 80 per cent of the difficulties. Obviously such a preliminary test of vitality will eliminate both the poor clinical and urological risks from future consideration in the analysis of results of suprapubic prostatectomy. In order to complete the statistics of any series, we believe that the failures in operation, whether by catheter or cystotomy, should be accurately listed.

A more careful study of suprapubic results shows that even this operation is not so universally successful in effecting cures as many would have us believe. The general results, our own personal results in fact, are most discouraging, and it is only in the hands of experts, just as in the case of the perineal operation, that anything like satisfactory results are obtained. Whiteside found only about 30 per cent cures with mortality of over 20 per cent in general hands, and these findings have been more recently confirmed by Thomas. Two in every ten cases did not survive the opera-

tion, and three of the eight who did were not cured. Because the operation is technically easier than the perineal does not prove its simplicity nor justify its universal practice. Its successful execution requires training, and without that training the results will be poor.

Our own poor results in thirty-eight cases suprapubically are briefly given below in comparison to those obtained in ninety cases perineally.[2] In addition, six suprapubic failures of other surgeons, four of whom we know to be expert specialists, have come under our care during the last five years, whereas in the same time we have seen only two perineal failures of others. Five of these first had suprapubic fistulae persisting since operation for four, three, two and one years, and four months, respectively. Urologic and cystoscopic study showed marked structural defects in all six and all were complete functional failures. Cancer or vesical diverticula were definitely absent in all and, therefore, not factors. None of our own suprapubic cases were operated until after considerable experience in bladder surgery and after careful study and observation of the technic of many operators. The results, therefore, cannot be blamed wholly to poor surgery. The six total failures of others, much worse than any of our own, who are frank suprapubic exponents, appeases our conscience in this respect.

Mortality statistics following prostatectomy are fairly complete. The perineal has been universally found to be the more benign procedure. Personally we have now eighty-one consecutive unselected cases successfully operated without death, our total mortality by perineal prostatectomy being 2.2 per cent.[3] Our experience suprapubically has been most unfortunate—six deaths and one suicide in thirty-eight cases, or a mortality of 15 per cent, and we cannot help but believe, in view of most of these cases being good surgical risks, that the majority would have survived, and now be living and well, had they been operated by way of the perineum.

The suprapubic cases have a distinct advantage with respect to the surgical and urological risk. They were selected on the basis of typical intravesical enlargements in good clinical condition. Of the suprapubic cases 84 per cent were in good clinical condition as compared to only 34 per cent of the perineal cases. The average age was sixty-four as compared to that of sixty-eight for the perineal. Prostatism was neither so advanced nor complicated so that surgery being successfully performed, there was good prospect of cure in 80 per cent, fair prospect in 15 per cent, and a poor chance in only 5 per cent, as compared to the urologic risk for the perineal cases of good, 60 per cent; fair, 16 per cent, and poor, 24 per cent.

An effort has been made to determine by cystoscopic and urologic study, occasionally by cystography, the late structural result of operation. Forty-eight perineal cases on an average of two years after operation, and eight suprapubic cases on an average of two years, have been so studied, with the finding of 68 per cent good structural recovery perineally, but only 38 per cent suprapubically. Thirty-two per cent of the perineal cases had fair repair of the prostatic urethra and sphincter, while one-half of the suprapubic cases were so classed. There was one failure among our earlier perineal cases, of structural restoration, a case of incomplete enucleation, whereas 12 per cent of the suprapubic cases were structural failures.

Good structural restoration is the most important factor in either perineal or suprapubic prostatectomy in securing a good functional result. The defects in structure may be the result of changes produced by the enlargement or by the surgeon, but sometimes by both. The defect common to suprapubic enucleation is the persistence of a larger or smaller prostatic cavity communicating with the bladder either by a wide funnel-shaped neck or a narrow contracted orifice. The latter are the type difficult of instrumentation or catherization. Plication of the prostatic mucosa after the removal of large glands is the common defect following perineal prostatectomy. Tags of mucosa or hyperplastic nodules or even lobes left at the vesical neck or some portion of the prostatic cavity, are common to both methods, but are more apt to occur after perineal prostatectomy because of the common practice of removing the hyperplasia in one intact mass suprapubically and not by separate lobes or portions as is usually done perineally. It is this particular difficulty in the performance of a successful perineal operation that has appealed to the writer as the principal cause of the general disfavor of the operation, rather than the difficulty of anatomical approach, for it is this difficulty of complete, clean enucleation that leads to poor functional results or later to a recurrence of prostatism, on account of all the gland not having been completely removed. En masse enucleation with divulsion of the prostatic urethra simplifies this step of the operation and secures complete removal. We have described a procedure, with this object in view, that has now been used with slight modifications in our last twenty-five cases with 100 per cent functional cures. Just as good preservation of sphincters, veru montanum and ejaculatory ducts is possible as by Young's technic, and it has the added advantage of a more certain complete removal of all the hyperplasia, secures a better structural result, quicker surgical healing, and does not require so much technical skill to obtain what has been emphasized as the important step of any operation, a complete, clean removal.

The functional results of all cases have been determined by the careful questionnaire,* answers

---

2. Reported in detail before the Montreal meeting of the American Urological Association, June 3, 1921.

3. We have had two deaths in ninety cases (June, 1915-April 30, 1921) operated since leaving Johns Hopkins, but we had two in the twelve cases operated by us while resident under Dr. Young at the Johns Hopkins Hospital, and in all justice to our statistics, these are excluded (4 deaths in 102 cases).

to which have been received from sixty-five perineal and twenty suprapubic cases. Perineally, there are 83 per cent cures, 7 per cent improvements and 10 per cent unimprovements, or poor functional results, as compared to 38 per cent cures, 19 per cent improvements and 43 per cent poor results suprapubically. The patients were asked to answer the direct question, "Do you consider yourself cured?" Eighty-nine per cent of the perineal cases said "Yes" unqualifiedly, while only 70 per cent of the suprapubic cases were so well satisfied as to admit a cure. The morbidity among the sixty-seven perineal cases is 16 per cent (eight deaths "since operation," two "at operation") as compared to a morbidity of 33 per cent suprapubically (three deaths since operation, six operative deaths). The deaths since operation of the perineal group would naturally be higher (15 per cent) than the suprapubic (10 per cent), because of the preponderance of poor clinical risks and generally more advanced age of this group.

SUMMARY

This analysis clearly demonstrates that in our hands Young's perineal prostatectomy excels the suprapubic operation in every respect. It has given a lower mortality, 2.2 per cent, as against 15 per cent; and a higher percentage of cures, 83 per cent as against 38 per cent, even in spite of the handicap of less promising material. We now have eighty-one consecutive unselected cases successfully operated by way of the perineum without death. Recto-urethral fistulæ, persistent perineal fistulæ and incontinence have been absent in all our later cases and at no time troublesome, and, though five years is the longest time since operation, we have yet to have one case return with a recurrence of prostatism.

The generally poor results that have been reported for Young's perineal prostatectomy are, in our opinion, directly blamable to the inexperience of the operator rather than the fault of the operation. With other types of perineal operations we have had no experience. Properly performed, Young's is an ideal surgical procedure, but presents two types of technical difficulty—the anatomical approach and the actual glandular enucleation. Errors in the first lead to injuries of the rectum or external sphincter; in the second, to structural defects, with either persistence of prostatism or its recurrence.

Prevention of surgical errors in the anatomical approach comes by experience and a knowledge of the anatomy of the perineum; prevention of the structural defects is best secured by a complete, clean removal of the hyperplasia. This is simpler and more certain by the modified method of enucleation whereby the hyperplastic mass can be accurately dissected out intact under direct control of the eye. In the twenty-five cases in which this perineal en masse enucleation has been used, the immediate and later results have been most gratifying, 100 per cent functional cures.

* Questionnaire

I. **Urination:**

1. What is your frequency of urination?
   (1) Give the average number of voidings during the day ———
   (2) Do you get up at night to void?
      (a) Give the average number of times ———
      (b) Give the approximate time of night that these voidings occur ———
2. Do you have burning on urination?
3. Do you have hesitancy of urination?
4. Do you have difficulty of urination?
5. Do you have dribbling of urine?
   (1) Is this at end of urination?
   (2) Is this between urination? ———
   (3) Have you good control of urination?
6. What is the character of your urine (1) Clear ——— (2) Cloudy ———
7. Have you had a swollen testicle (Epididymitis)? If so was it
   (1) Before operation?—Right ——— or left ———
   (2) After operation and while in hospital?—Right ——— or left ———
   (3) Since leaving hospital?—Right ——— or left ———

II. **Sexual Ability:**

Regarding your sexual life since operation:

1. Have you sexual desire? ———
2. Do you have erections? ———
   (1) Are they satisfactory? ———
   (2) Or unsatisfactory? ———
3. Have you had sexual intercourse? ———
   (1) If not, has it been attempted? ———
   (2) Or not attempted ———
   (3) If so, give average frequency and character ———
4. Is ejaculation complete? ———
5. Do you have seminal discharge? ———

III. **General Condition:**

1. Do you consider yourself cured of your prostatic trouble? ———
   (1) If you do not, please describe the character of your present disability ———
2. How does your general health, since operation, compare with what it was just previous to operation? ———

(516 Sutter Street)

Throwing Away Our Birthright—"The immigration problem can never be settled wisely and justly unless it be settled by those who have a vision of what the United States stands for. The United States will cease to be the land of opportunity unless we preserve unsullied and undiminished the ideals by which, and on which, this republic was created. The foreigner who hopes by plotting to win advantage for his creed over here, though he were twenty times naturalized, would remain a foreigner. He who seeks to involve the American States in the political or religious quarrels of the country from which he came is no American; he is a traitor of the baser sort. That citizen who would use his country for his private gain deserves to be uncitizenized. No true American will consent to the admission to our country of foreigners who will lower its standard in health, in morals, in intelligence, or in patriotism. Until we realize that we have inherited a sacred trust and that we must preserve it sacredly, we, too, are but imperfect Americans." (William Roscoe Thayer, in the North American Review of February.)

There is more in this article that is worth the time of any physician to read. The basic principles of right and wrong in adequate immigration laws and in effective law enforcement are medical.

THE DIFFERENTIAL DIAGNOSIS OF ECZEMATOID DISEASES

By SAMUEL AYRES, JR., M. D., Los Angeles
From the Department of Dermatology, White Memorial Hospital, Los Angeles

Anyone who comes into daily contact with patients suffering from skin diseases must be aware of the confusion which exists in the minds of most physicians and practically all of the laity in regard to that elusive dermatological scrap-heap called eczema. From the standpoint of treatment, some so-called cases of eczema differ from each other as widely as diphtheria and syphilitic sore throat. The purpose of this paper is not to offer a treatise, dealing minutely with all the possible diseases which are capable of being confused with eczema, but to indicate in a general way that there are a number of very definite and well-recognized diseases which may simulate eczema, but which must be treated according to their individual requirements. Since the etiology of many of these conditions is unknown their classification is naturally a matter of controversy and will remain subject to revision.

Darier,[1] one of the leading French dermatologists, emphasizes the fact that the eruption known as eczema is not limited to a single and specific cutaneous disease, but is a relatively common mode of inflammatory reaction of the skin toward a variety of irritants, either of external or internal origin. It is analogous to the symptom of abdominal pain, which is a mode of reaction to such widely differing causes as lead poisoning, gall stones, tabes and appendicitis.

The Eczematous Reaction.—The lesion which, above all others, is characteristic of the eczematous reaction is the vesicle, but it must be clearly understood that the vesicle is only one of a number of eruptive elements which may follow each other in a definite sequence, may co-exist, or any one of which may dominate the picture. The usual order in the appearance of the lesions is as follows: Erythema, sometimes gross edema, vesiculation, exudation, crusting, lichenification or thickening, and desquamation of crusts or scales. Papules sometimes occur, but they are frequently surmounted by vesicles or oozing pores. Pustules may result from secondary infection. Vesiculation may be so intense and confluent as to produce raw, oozing surfaces. The eruption typically passes through these stages, but it may become arrested in any one of them and continue indefinitely. In such cases, however, a few lesions typical of other stages usually occur from time to time. The onset may be acute or gradual, but the condition tends toward chronicity, frequently with acute exacerbations. The process is an inflammatory reaction, involving both epidermis and corium. The lesions are arranged in spots or patches, usually with ill-defined outlines, and are attended by a considerable amount of itching or burning. The fact that the eczematous reaction may pass through so many phases accounts in large measure for the confusion that exists.

Histologically, as well as clinically, the principal lesion of the eczematous reaction is the exudation of fluid. This begins in the corium with hyperemia, edema, and perivascular infiltration, especially in the papillary body. The plasma, which is more in the nature of an inflammatory exudate than a mechanical transudate, tends to collect in the prickle cell layer, where it infiltrates between the cells, pushing them aside and forming spaces or vesicles between them. These vesicles usually form in the deeper layers and rising to the surface with the upward growth of the cells, enlarge by further accretions of plasma and by confluence with neighboring vesicles. The vesicles may dry without rupture if the inflammation is mild, or as more commonly happens, they break through the surface of the skin, giving rise to the clinical picture of "weeping." If the edema is severe, these ruptured vesicles may remain open as oozing pores for the outlet of the plasma, which is constantly forming below. Under these circumstances secondary infection often results. Two other important histological changes are: defective cornification of parakeratosis, and in long-standing cases, an increased thickness of the prickle layer or acanthosis, which is due both to the edema and to increased cell growth.

Eczema.—There is no adequate reason, clinically, histologically, or therapeutically, for differentiating between "true eczema" and dermatitis venenata or external eczema. The etiology should be ascertained, if possible, in every case, and the treatment naturally will be modified to a certain extent, depending upon the cause. Sometimes the localization of an eruption will suggest an external origin as for example, the eruption on the hands, arms, face, and exposed part of the neck from poison ivy. The poisonous plants usually produce a more severe and acute type of eruption with greater edema than the eczemas of internal origin; the vesicles develop rapidly, cover extensive areas on exposed parts, later also on covered parts by auto-inoculation, and are closely crowded. They sometimes occur in linear arrangement due to the contact of a leaf or branch. Practically, any substance may irritate an especially sensitive skin, or even a resistant skin if applied often enough and long enough. Many cases of eczema are caused by overzealousness in the use of soap and water. A persistent dermatitis on a limited area, due to frequently repeated contact with an irritant such as chocolate in candy dippers, may in time, through a process as yet unknown, possibly allied to anaphylaxis, cause a lowered resistance or hypersensitiveness of the whole body surface so that the entire skin may become involved.

Some of the internal causes of eczema are: food anaphylaxis, other obscure gastro-intestinal derangements, chronic nephritis, diabetes, varicose veins, etc. An adequate search for the causative agent, therefore, frequently requires not only a careful and searching history, but a complete physical examination, urine tests, renal function determinations, anaphylactic skin tests, etc. All of these measures sometimes fail and symptomatic treatment is all that can be offered.

Eczematoid Diseases.—Epidermophytosis is prob-

ably the most recent disease to be rescued from the eczema junk-pile.[2] It is caused by a fungus, the epidermophyton inguinale, which under the microscope is seen to be made up of spores and mycelia; culturally, it differs from the related tineas, which cause ringworm and other parasitic diseases.[3] The recognition of this disease represents a synthesis of conditions which formerly were supposed to be unrelated. It is not always an easy matter to demonstrate the organism under the microscope. For this purpose scrapings should be taken from the deeper layers of the lesions; they should be immersed in 40 per cent potassium hydroxide on a glass slide and heated until bubbles form beneath the cover-glass.

The lesions develop and spread rather slowly; a single small patch on the hand or foot may remain localized for months and sometimes a year or more. In the genital regions, the development is more rapid. The points of election are areas where perspiration is most abundant such as the genito-crural regions, the axillæ, the interdigital spaces of the fingers and toes, the palms, the soles and sides of the feet, and sometimes the flexures of the knees and elbows. Individuals who have excessive sweating of the hands and feet are especially susceptible to the development of epidermophytosis in these locations. Between the fingers and toes the lesions consist chiefly of maceration, scaling, or a white, sodden appearance. On the palms and soles there is thickening, scaling, redness, and scattered deep-seated vesicles and vesicopustules. Here the disease very closely resembles pompholyx or dyshidrosis, but the clinical differentiation lies in the fact that pompholyx is less inflammatory, shows very little scaling and more vesiculation, and occurs in definite attacks lasting from four to six weeks, completely disappearing between attacks. Epidermophytosis frequently becomes less active during cold weather, but it may persist for months or years in some degree of activity if untreated. The lesions of epidermophytosis, pompholyx and eczema of the palms are all very itchy. In eczema there is more oozing and fissuring, and the lesions also occur on the backs of the hands, wrists, and sometimes the arms; the fungus cannot be demonstrated. Syphilis and psoriasis of the palms and soles are both dry, have no vesicles, itch little or none, and have more sharply defined margins. There are usually other evidences of these diseases elsewhere on the body. In the genito-crural regions the lesions form large red patches with little or no elevations except possibly to a slight extent along the borders. The margins are sharp, slightly scaly, and run in fairly straight lines or in a festooned design. There are frequently a number of small outlying lesions. The eruption may be bilaterally symmetrical, but is often asymmetrical. The centers of the lesions are either dry or more usually glazed in appearance, but almost never frankly oozing.

Two other diseases involving the axillary and genito-crural regions must be differentiated from epidermophytosis. Erythrasma is caused by a much smaller fungus, the microsporon minutissimum, the lesions develop more slowly, they are more superficial, scaly, and are of a pink or buff color rather than red as in epidermophytosis. The treatment, consisting of strong anti-parasitic ointments, is the same for both conditions, and is in striking contrast to the treatment of eczema. Intertrigo is a dermatitis due to local, external causes, and may occur in two stages of development—intertrigo erythema and intertrigo eczema. Some of the causes are: insufficient bathing, excessive sweating, friction, as after a long march, fermentative diarrhea in infants, leukorrhea or diabetic urine in women. Secondary infection is common. This disorder always involves contiguous surfaces, is symmetrical, and has more diffuse borders.

Ringworm of the body is a diagnosis too frequently made. The lesions are usually few in number, are circular, tend to clear in the center and to spread peripherally with a sharp border made up of minute vesicles and crusts. It is important to remember, however, that a circular lesion with a sharp border does not always spell ringworm. Chronic recurring, localized eczemas, seborrheal eczemas or eczematides, the early lesions of mycosis fungoides, infectious eczematoid dermatitis, and other conditions, may all have very sharp borders. A microscopic examination of scrapings taken from the border of a lesion will usually reveal the spores and mycelia, if due to ringworm.

Scabies ordinarily is easily recognized, but if through lack of cleanliness and excessive scratching the lesions become eczematized and secondarily infected, or if the skin becomes irritated from overtreatment, the diagnosis may not be so clear. An oozing, crusted eczema of the breasts in women should arouse a suspicion of scabies, for the female breast is one of the areas of predilection for the parasite. In such questionable cases, a careful search for burrows should be made between the fingers and toes and about the wrists. With care, the acarus scabei can be picked out of one end of a burrow on a needle-point, and can be demonstracted under the microscope.

Pediculosis, whether of the head, body, or pubic region, in the absence of cleanliness may give rise to secondary eczematization from scratching and bacterial infection. Extensive pediculosis of the scalp is often responsible for an eczematous eruption of the face, neck, and upper part of the chest. Finding the eggs or "nits" in the hair of the scalp or pubic region, or in the seams of the clothing, is strong confirmatory evidence.

Among the local bacterial infections which resemble eczema, probably the most recent to be recognized as a distinct entity is infectious eczematoid dermatitis, first described by Engman of St. Louis, in 1902. The infection may have its starting point in a furuncle, an impetigo, an infected wound, a chronic discharging ear, or any overtreated skin condition. A frequent history is that a boil or an infected wound was bandaged, and the bandage not removed for several days. The resistance of the tissues thus bathed in pus becomes weakened, and the characteristic dermatitis is the result. Most cases are auto-inoculable. Sutton,[4] of Kansas City, has found the staphy-

lococcus aureus in pure culture in most of his cases, although the albus occurs occasionally. The eruption is asymmetrical, usually on exposed areas, and is in the form of circumscribed patches with redness, oozing pores, vesicles, pustules, vesico-pustules, and crusts. The lesions spread peripherally, and the epidermis at the border is split or undermined; there is little or no tendency for the center to heal spontaneously. The disease may respond readily to appropriate antiseptic treatment, but it may persist for weeks or months. There is practically never any pain or itching.

Dermatitis repens is another chronic infectious disease, also frequently caused by the staphyloccus aureus. It is relatively uncommon, bears a faint resemblance to eczema, and is usually rebellious or recurrent. Clinically, only a few lesions are present, the areas of involvement most often being the hands and feet, but no regions are exempt, and lesions may be present on the neck, arms, axillæ, genito-crural area, etc. The lesion begins frequently at the site of a trivial injury. There is a red spot at first, which, in the course of a day or more, acquires a central flaccid vesicle or vesico-pustule, which on rupture shows a small amount of clear or milky fluid. The lesion enlarges peripherally, showing a ragged, undermined border, from under which the same clear or milky fluid exudes. The center becomes raw or glazed or sometimes crusted, and usually heals spontaneously while the borders are still advancing. An individual lesion may remain stationary for weeks, months, or years, or it may slowly spread, or it may entirely disappear and later recur. Subjective sensations are slight or absent. The disease was first described by Crocker, in 1888.

Impetigo usually offers no difficulty in the way of diagnosis, unless through lack of care or cleanliness or by overtreatment the course is prolonged. Under these circumstances it may take on an eczematous aspect; in fact, it may become converted into an infectious eczematoid dermatitis.

Among the diseases of unknown etiology resembling eczema, the commonest and most frequently mistaken is seborrhoic dermatitis or seborrhoic eczema, or according to Darier, eczematide, a condition which is presented in admirable detail and clarity in his recent text-book on dermatology which has been translated into English by Pollitzer.[5] Although eczematides and eczema show clinically imperceptible transitions, and histological lesions which are nearly identical, Darier cites the following four reasons for placing eczematides in a separate class: 1. Their usual dryness; 2. The sharpness of their rounded or polycyclic outlines; 3. Their very prolonged persistence under the same aspect; 4. Their very ready curability under the influence of appropriate local treatment. Although vesiculation frequently occurs in eczematides, the fluid is small in amount as compared with eczema, and the vesicles usually dry and become crusted without rupturing. Without attempting to describe all the clinical varieties of this disorder, it might be profitable to mention some of the characteristics of the commonest type, the figured or seborrheal eczematides. The areas of predilection are the sternum, between the scapulæ, the scalp, behind the ears, and the forehead just below the hair-line. The lesions itch moderately or only very slightly, sometimes in the scalp very severely. They occur in spots or patches with rounded, polycyclic, sharply defined margins which may be slightly elevated. The centers may heal as the borders spread. The lesions are usually covered with greasy or fatty scales.

Pityriasis alba or simplex is a benign but very persistent disease of childhood, mildly contagious, and of unknown cause. It is usually diagnosed as "dry eczema," but may be related to the eczematides. The lesions are most common on the face, especially about the mouth and chin or on the cheeks. They are superficial, dry, scaly, flesh-colored or white. The outlines may be very indistinct, but are sometimes sharply defined and polycyclic. The lesions may become eczematized. There is usually no itching.

Lupus erythematosus is a dry, scaly eruption which usually does not occur till after the second decade of life. Characteristically, it involves the bridge of the nose, extending to the flush areas of the cheeks in the form of a butterfly. It may occur elsewhere on the body. It is chronic, but may develop rapidly. The lesions are superficial, and centrally show a certain amount of surface atrophy. The borders may advance slowly or may become stationary. The mouths of the sebaceous glands, especially about the edges, are dilated and filled with horny plugs. There may be slight itching or burning during active periods. Evidence for the tuberculous origin of lupus erythematosus is entirely inadequate and contradictory. When the eruption does not appear in its characteristic location on the face, it is very often called dry eczema, but the features described above should serve to differentiate it.

There is small excuse for failure to recognize the dermatitis occurring in pellagra since the clinical picture of the disease has been so carefully worked out. The diarrhea, the sore tongue, the loss of weight, the mental and neurological disturbances are all corroborative evidence. The dermatitis itself, however, is sufficiently characteristic: the greatest involvement on exposed areas, the sharpness of the borders, the almost perfect bilateral symmetry, the dry roughness, the color—at first red, later brown, sometimes with a chocolate or purplish hue.

Lichen planus is always a dry eruption except in an extremely rare variety. The itching is sometimes intolerable. The areas of predilection are the flexor surfaces of the wrists and forearms, the shins, the external genitals, and the buccal mucosa, but no region is exempt. The lesions are flat-topped, angular, shiny, violaceous, sometimes umbilicated papules which, on an average, are about the size of a pin-head, and are arranged in patches, plaques, or streaks. Discrete lesions are usually found beyond the borders of the plaques. In the mouth the patches are white and have a cross-hatched appearance.

The erythrodermas constitute a heterogenous and ill-defined group of diseases, characterized by

redness in patches or large areas, usually of universal distribution, intense itching, dryness, and scaling. Some arise spontaneously, others are secondary to previously existing dermatoses, such as eczema, psoriasis, acute lichen planus, eczematide, etc. The skin is usually dry, but in severe cases there may be maceration and oozing in the articular folds or where fissures develop. All of the diseases in this group are extremely rebellious to treatment, and many of them end fatally. Although the etiology is unknown, febrile reaction, mortality, and such severe involvement points to the probability of a profound toxic disturbance somewhere. Leukemia sometimes manifests itself in the skin as erythroderma.

Mycosis fungoides, which is apparently a cutaneous lymphoma, may in its early stages masquerade for many months as eczema or as erythroderma. The resemblance to eczema is often striking, there being intense itching, oozing, and redness. The patches are too sharply outlined, however, and often are arranged in discs, ovals, crescents, or other designs, which should arouse one's suspicions that he is dealing with something other than eczema. The lesions are very resistant to all treatment except the X-rays, but will in time disappear spontaneously, to be followed, however, by the characteristic fungating tumors, which in the course of months or possibly a year or two, always terminate in death. In the early stages a microscopic examination of the tissues will usually serve to confirm the diagnosis. Sometimes a blood examination will reveal a pronounced leukemia; one case showing this combination came under my personal observation.

Dermatitis herpetiformis is almost never correctly diagnosed except by physicians who have a wide experience in skin diseases. It was first described and named by Duhring about thirty-five years ago. The disease may be toxic in origin, but the almost perfect bilateral symmetry of the eruption in most cases suggests an involvement of the nervous system as part of the process. The eruption is multiform: on different parts of the same patient may be seen erythematous patches, vesicles, bullæ, papules, pustules, crusts, scars, and pigmentation. The characteristic lesions are groups of vesicles on erythematous bases, which go through the whole range of evolution, sometimes with secondary alterations, ending in pigmented scars. The lesions itch severely and are sometimes painful. The natural history of the disease is a succession of persistent, rebellious attacks, lasting weeks or months, alternating with periods of complete or nearly complete freedom from the disease. The characteristics described above, especially the symmetry, should serve to differentiate the condition from eczema.

Erythema multiforme, pityriasis rosea, tinea versicolor, and psoriasis could hardly be confused with eczema except by the most inexperienced, unless a secondary dermatitis had been produced by improper or excessive treatment.

SUMMARY.

Many dermatoses commonly diagnosed as eczema are distinct clinical entities, which in some instances require treatment that is diametrically opposed to that of eczema.

Eczema is not a single and specific disease, but is more in the nature of a symptom or mode of reaction on the part of the skin toward a variety of causes acting both internally and externally.

Whenever eczema is written as a diagnosis, the etiology, if ascertainable, should be included.

The failure to differentiate between eczema and conditions which more or less closely resemble it, and the failure in cases of true eczema to make an adequate search for the cause, account in large measure for the reputation which eczema has acquired of being an uninteresting and incurable disease.

ST. LOUIS MEETING OF THE AMERICAN MEDICAL ASSOCIATION

The arrangements for the National Convention of the A. M. A. are singularly convenient for delegates and members who are planning to go from California and other Pacific Coast States. The 1922 convention of the Medical Society of the State of California will open in Yosemite National Park May 15, and will close May 18 in time for those going to the A. M. A. Convention to reach St. Louis for the opening session May 22. We are informed that the grouping of the meeting places shows a decided improvement over the accommodations which were offered by St. Louis at the 1910 meeting. Allied Sections are so closely grouped together that those who attend the convention may travel from section to section in from one to five minutes.

The registration office, postoffice and commercial exhibit is to be in the Moolah Temple (Shrine), a beautiful and commodious building on Lindell Boulevard, two blocks west of Grand avenue. At the other extremity of the group is the Odean, with a main hall which seats more than two thousand, and several lesser halls. The main hall will be used for the opening session.

The St. Louis profession is preparing for an unusual attendance; hotel reservations are reported as coming in rapidly, but it is purposed that even the late-comer shall be comfortably housed. Dr. M. B. Clopton, 3525 Pine street, St. Louis, is chairman of the Committee on Sections and Section Work.

ORAL FOCI OF INFECTION, THEIR DIAGNOSIS, DIFFERENTIATION AND SYSTEMIC MANIFESTATIONS.*

By ROBERT BURNS, JR., D. D. S., San Francisco

Diseased teeth and their surrounding tissues are often factors in ill health. Physicians frequently fail to utilize this fact in diagnosis and treatment. A cursory inspection of the mouth and a radiogram do not furnish sufficient data to warrant conclusions. The judgment of the dentist is often inadequate because by education and habit he is primarily concerned with saving teeth and his training in pathology is restricted to a very narrow field. Dentists are inclined to look upon a tooth as something apart from the rest of the human economy to such an extent that to many an abscess is a "gum boil" to be shut off from all drainage by sealing in with a patent medicine.

The diagnosis of foci of infection in the oral cavity is not always a simple matter. Both physicians and dentists need to study more in detail the anatomy and pathology of the oral tissues. If the dental profession is too mechanical in its bent, scornful of the fact that infection at the apex of a tooth is more dangerous than the more drainage free infection in a tonsil, no small portion of the blame rests with the medical profession. For back in 1840 when the dentist, Chapin Harris, sought to interest the medical men of Baltimore in the establishment of a course in dentistry in the medical school he was repulsed. So he established the Baltimore College of Dentistry, the first dental college in the world, a movement that has resulted in an immeasurable amount of good, but after all a colossal mistake, for it set up as separate and as things apart two professions that should have beeen as one.

In the consideration of oral pathology, particularly with reference to systemic sequelae, I desire to lay especial stress upon the fact that a tooth is no more nor less than bone,—highly specialized bone,—hence possibly a little more prone to disease, and that with its investing tissues as it rests in its alveolus, we have represented a joint,—no more no less. An appreciation of this fact may help make clear why one of the most common results of peri-dental infection is an impairment of some other joint in the body (arthritis).

Let us consider the principal structures of the teeth.

Pericementum is the analogue and the homologue of the periosteum of bone. The only modification is that the periosteum of bone lies between a hard and a soft tissue while the pericementum of a tooth lies between two hard tissues.

Cementum in its function is unique in the body. Broadly speaking its only purpose is to act as an enveloping pad for the root of the tooth to reduce the impact of mastication and to afford attachment for the fibers which maintain the tooth in the socket.

Cementum is exceedingly thin, varying from 1 to 250 microns—say 1/100 of an inch. It is entirely structureless, devoid of any histological pattern, devoid of cells, blood vessels, nervous system or lacunae. Its viability is maintained solely by the pericementum, a point of very great significance in considering the prognosis of peridental infections. Cementum is laid down in practically the same manner as the intra-membraneous ossification of bone: that is, upon osteogenetic fibres of connective tissue are deposited masses of small globules, the product of numerous round cells functioning as osteoblasts.

Dentin forms the greatly preponderant bulk of the tooth. It closely resembles bone. It is of mesodermic origin and its cells are similar histologically and in physiological function to cementum. It is not hyaline in character as is cementum, which, in this respect, resembles cartilage.

It contains about 28 per cent of organic matter and throughout is penetrated by a mass of tubuli with an enormous number of branches anastomozing freely. These tubuli are from 1 to 3 microns in diameter. They have their origin at the pulp and terminate at the Granular Layer of Tomes. Through them pass the Fibres of Tomes which are protosplasmic projections of the odondoblastic or genetic cells of the pulp—erroneously spoken of as the "Nerve" of the tooth. Of the pulp Noyes [1] says: "The vital function of the pulp is the formation of dentin and is performed by the layer of odontoblastic cells. These cells also, by means of their dentinal fibrils, maintain the same relation to the dentin matrix that the bone and the cement corpuscles bear to the matrix of bone and cementum. *When the pulp is removed* from a tooth its dentin becomes *dead* dentin in the same sense that bone in which the corpuscles have been killed is necrosed bone." (Italics mine.)

The sole blood supply of the bulk of the tooth proper, the dentin, is received by minute arteries passing into the root canal through the apex through which passes also its innervation. The blood is returned by a complete venous system and Schweitzer [2] has demonstrated the presence of lymphatics as well. Thus when a dentist "kills the nerve" of a tooth undoubtedly we have a dead tooth, though some men euphemistically insist that it is just merely a "pulpless" tooth! These facts explain why 80 per cent of dead teeth are infected.

The granular Layer of Tomes marks an absolute and impenetrable line of demarcation between the dentin within and the cementum with its pericementum without as shown by Marshall.[3] So that when the "nerve is killed" we have absolutely destroyed beyond recovery all blood and all nerve supply to the dentin and the granular layer of Tomes prevents the possibility of any collateral circulation from the pericementum. Wherefor I hold that every dead tooth is a potential source of danger and in the presence of symptoms should be surgically removed.

Oral foci of infecton, just for convenience, I have divided into three groups. (1) infections, acute or chronic about the apices of teeth; (2) gingivitis, pyorrhoea and infections about un-

* Read before the St. Francis Hospital Clinic Club.

erupted and impacted teeth; (3) old lesions in the maxillae or the mandible due to failure of removal of infection when teeth have been removed. The latter class are more common following the ordinary "pulling" of teeth either with or without blind attempts at curetment of the sockets, than following what for a better term we may designate "surgical removal" of teeth. Such lesions are often found in mouths entirely edentulous as are also fragments of teeth broken in attempts at pulling.

Group one are due in the great preponderance of cases to death or removal of the pulp. Death of the pulp may be caused by caries, trauma, direct as from physical injury, indirect and less violent such as results from undue stress in mastication when a filling is left too high, or when due to the irregularity of the teeth so that a particular tooth receives more than its share of stress. Similar results may be brought about following the extraction of one or more teeth, if the others, through the lack of support by continuity of the arch, move out of place. The same holds true when teeth loosen and move in pyorrhea. In these forms, death of the pulp may occur very insiduously and be entirely unsuspected by the patient, much less by the physician and often are difficult to determine by the dentist. Often the only positive means of diagnosis is actually to drill into the tooth a sufficient distance to determine the state of the pulp. This point alone emphasizes the importance of ordering complete radiographs of all the teeth and the edentulous spaces as well, rather than merely a few suspected teeth.

Given a tooth in which the pulp has died or been removed, the mere physical factors render successful treatment extremely dubious, for we have a minute root canal of capillary dimensions at the apex and it may even be tortuous. From this canal we must remove every vestige of broken down, infected tissue. Then we must render this tube sterile. Beyond this we must sterilize the maze of tortuous interlacing tubuli throughout the dentine and maintain this sterility. It simply can't be done yet. Following this we must seal the apertures of these tubuli as they open into the canal and seal the canal against both efferent and afferent bacteria or toxins. A common procedure in dentistry employed to cleanse the canal is to introduce a mixture of sodium and potassium in minute quantities. At once a violent reaction occurs as soon as the chemicals come in contact with the moisture. Fortunately the intense heat created can not do a great deal of harm in the canal, but think what must be the result upon vital cells when, as sometimes happens, that sodium and potassium passes out into the bone. Some men use sulphuric acid followed by soda bicarb. Some seal a mixture of equal parts formalin and tri-kresol. I wonder how any of these formulae would appeal to surgeons if suggested for the removal of a T. B. infection in a hip joint or a knee joint. And do not forget that a tooth in its socket is no less a joint.

After this cleansing of the canal remains the necessity of making it bacteria proof. Some think they succeed in this by attempting to pump down just exactly to the apex some form of solid dissolved in a solvent followed generally by a gutta percha point packed in as tightly as may be. The liquid first portion is usually gutta percha in chloroform or in eucalyptus, or fiddle bow resin in chloroform. It strikes me as simply assinine to think that after the evanescent solvent has disappeared the resultant canal filling will be as dense as it was before and that it will bar passage to bacteria or to toxins. Price [4] of the National Dental Research Institute has established the co-efficient of contraction of our canal filling materials, so much so that not many dentists now seriously claim that they actually seal canals. Some fall back upon their belief that cementum will sometimes grow over the apex of a pulpless tooth. At best such cementum is purely hyperplastic and its presence is prima facie evidence of an abnormal condition the result of irritation. Furthermore if the cementum ever is denuded of its pericementum it never will repair itself nor can it oxfoliate, but will remain permanently necrotic unless removed by surgical interference. Upon which evidence I assert that when a good radiogram indicates such a denuded condition about a dead tooth that tooth is doomed unless the patient, banking upon an absence of demonstrable symptoms, is determined to bet his powers of resistance against the menace. Bearing upon this factor it may be mentioned that recently, addressing a meeting of the Association of Railway Surgeons, Martin Fischer asserted that diseases of the vascular system, so often unobserved until very definite and dangerous lesions are manifest, have their inception in minute foci of infection which have been of long standing and slow progress. Striking support of this view can be found in a preliminary report by Ophuls [5] of 500 consecutive necropsies had for the purpose of studying the relation of cardiovascular disease and of arteriosclerosis to infectious diseases. It was found that those cases wherein all history or signs of previous infection were absent, chronic arterial disease was almost lacking and made its appearance early and very frequently in the group where infection was known to have existed but was fairly well limited to chronic rheumatic (septic) conditions.

No better exemplification of such foci can be found than the slightly bleeding gums, usually the first noticed but also neglected symptom of a pyorrhoea that has been present for a number of years. Likewise granulomata at the apices of dead teeth rarely produce local symptoms.

The reason dead teeth may remain for years is that nowhere are they in physiological contact with other tissue save through the minute apical foramina and the organisms generally are of low grade, the degenerative process being slow. And yet through all the years there may be going on systemic disturbances equally slow and unobserved until unexpectedly there is observed a valvular

or a myocardial lesion or a cholecystitis or some other secondary lesion and even then the patient beyond hope of complete recovery.

The chief danger of gingivitis and of pyorrhoea lies in the insiduousness of their attack. Very often when they have reached the stage where they become apparent to the patient by reason of discomfort, the prognosis is decidedly unfavorable. More particularly is this true of pyorrhoea, for gingivitis, so long as it remains merely an inflammation of the gingiva, is entirely amenable to treatment which consists in removal of the cause—any irritation to the gum due to tartar, an ill-fitting crown, filling, or prosthesis of any sort, or irregularity of the teeth whereby food impactions occur about the gums. A gingivitis which, were it present about but one or two teeth, might be entirely negligible insofar as the possibility of systemic results were concerned, could very well be a serious matter were all of the teeth concerned because the sum total of the small ulcerating surfaces would represent a considerable area. For instance, it has been estimated that in the average mouth, if all the teeth were affected with pyorrhœa and the pockets averaged one quarter of an inch in depth, it would be equivalent to an ulcer approximating eight inches. I believe the dangers of pyorrhoea have been very much more underrated than overestimated. To begin with, practically nothing is established concerning its etiology and absolutely without exception, including those dentists who give it only the most perfunctory attention up to the men who do nothing else—the pyorrhoea specialists—all are attacking symptoms or end results, not causes. The first manifestation of pyorrhoea of which we become cognizant is an irritation of the gum, which later becomes detached from the root of the tooth. A pocket is formed, the pericementum is destroyed, the cementum becomes necrotic and all the structures infected. The dentist tries to cure this condition by scaling away the tartar, if any be present, and the dead cementum. If the pocket is not too deep, if access is such that all the necrotic cementum can be removed and if the pocket can be and will be kept clean and if the resistance of the patient is at par, in a certain percentage of cases there will be a cure—or at least a remission of the symptoms—and the best pyorrhoea specialists insist that their patients shall return regularly at intervals from one, three or six months for proper prophylaxis. In other words every pyorrhetic must be kept under exceedingly close observation.

In by far the greater number of cases there will be very scant abatement of symptoms, but constant exacerbations at varying intervals and renewed treatments, each attack accompanied by further loss of cementum, a progressive advance of the infection, until finally, if the patient lives long enough, the tooth will be lost. During all this time it is possible that there may have been no absorption sufficient to manifest any physical signs or symptoms. On the other hand there is great probability that great harm has been done and either the dentist should be qualified to recognize these manifestations or there should be very close co-operation with the physician. For it is just as certain that a focus of infection can lie in a pyorrhoea pocket as in a pus tube.

It may savor of heresy for one of my profession to say there is very strong evidence that the treatment of pyorrhoea should be under the control of the physician. No doubt I will be held temerarious at least to assert my opinion that pyorrhoea represents a failure of the medical profession. But I do so believe because Howe at Harvard maintained perfectly healthy guinea pigs on a scorbutic diet and produced lesions that could not be distinguished from pyorrhoea. When returned to their proper ration the lesions disappeared. Generally speaking, the systemic manifestations of oral infection are as varied as we would naturally expect from a low-grade chronic infection, while it must be ever borne in mind that in certain instances the characteristics are rather those of toxemia than of bacteremia. This I believe is markedly true, for example, in hypertrophic-osteo-arthritis, where cultures may be negative, and entirely a different matter from the definitely blood-borne arthritic infections. Yet in both instances the injury is due to the primary focus.

Following operations for the removal of foci of infection too often the patient, and sometimes the physician, fall into the attitude that now the teeth are out—I shall confine myself to oral foci—the patient is bound to get well without further care, without thought of possible secondary foci that may have been set up and from which it would seem the most natural thing in the world to expect an exacerbation of symptoms. Furthermore we often forget that after a long period of struggle with a low grade, persistent infection, wherein chronicity is the outstanding feature, patients develop a state approaching anaphylaxis. They become sensitized. Some effort at least should be made to desensitize them. The greatest effort should be put forth on the part of the internist to assist Nature in the rebuilding of the sufferer. Then it is, I am inclined to think, that autogenous vaccines, if used at all, might be used with the best hope for some benefit. This, of course, is a matter solely for the physician to decide.

By far one of the commonest disorders conjoint with oral infection is a disturbance of the nervous system. Our good old standby "neurasthenia," which so often saves our face, is probably as often due to oral focal infection as any other one thing. Let me quote the words of William Hunter in an address delivered at the opening of the session of the Faculty of Medicine of McGill University on October 3, 1910, published in the London Lancet January 11, 1911. He says: "I speak from experience. The worst cases of anemia, gastritis of all kinds and degree, of obscure fevers of unknown origin, of purpura, of nervous disturbances of all kinds, ranging from mental depression up to actual lesions of the cords, of

chronic rheumatic affections, of kidney disease, are those which owe their origin to or are gravely complicated by the oral sepsis produced in private patients by these gold traps of oral sepsis."

In the Journal of Dental Research for March, 1920, Lewellys F. Barker, M. D., very interestingly discusses the systemic manifestations of oral foci as drawn from the work at Johns Hopkins. He reports two cases that came under his observation where embolic infections of the lung appeared to be secondary to primary peridental infections. He further reports twenty cases of viridans endocarditis arising from septic teeth and in each instance the patient died. He says: "I desire at this time to emphasize the fact that the evidence is very strong that streptococcus viridans not infrequently enters the circulation from granulomatous areas about the teeth." Likewise he calls attention to "extra systolic arrythmia in which premature beats of one ventricle occur, a condition often associated with pyorrhoea as well as peri-apical granulomata of the teeth." The patients describe their sensation as though the heart were turning over. Referring to the practice at Johns Hopkins he adds: "We study the mouth in all cases of arterio sclerosis and arterial hypertension to see whether or not there is any source of infection there that may be of significance. We do this not only in cases of arterio sclerosis but in every patient who comes to us for a general diagnostic study. I feel sure that the condition underlying arterial hypertention may be aggravated by long-continued infection. Though chronic infection is by no means the only cause, it may, I believe, sometimes be an important contributing factor." Referring to the accepted fact that anemias may be due to acute or chronic infections, including oral sepsis, he says: "Whether oral sepsis can be the cause of a primary, or so-called pernicious anemia, I do not know; certainly a majority of patients exhibiting this form of chronic hemolytic anemia have infected teeth but this may be merely an accidental association." Thereupon he makes this significant statement: "Dead teeth and pyorrhœa are very common in pernicious anemia and the patients more rapidly secure a remission of symptoms if you clean up the gums and remove any peri-apical infection."

Now, just a very few statistics: Hartsell and Henrici, College of Medicine, University of Minnesota, failed to find bacteria in pulps of vital, normal teeth. Organisms were found 41 times in 93 vital pulps of pyorrhetic teeth. Streptococcus viridans was present in 29 of the 41. Staph. albus in 8 such.

Carl D. Lucas, May, 1920, before the Indiana State Dental Society reported 181 cultures from dead teeth and 71 from granulomata. Total 252.

Pathogenic organisms were obtained two hundred times, about 80 per cent. These scanty figures in themselves may not be very convincing. They are offered as simply typical of what various observers report, the aggregate of which are significant.

In 1917, before the Stomatological Section of the A. M. A., Arthur D. Black, A. M., M. D., D. D. S., Fellow of the American College of Surgeons, presented a tabulation from six thousand radiographic films of teeth and the adjacent bone in the mouths of six hundred adults. Fifty-five per cent gave evidence of bone involvements. We know that a great deal of infection exists that is not indicated by the X-ray, so the actual percentage of infection was undoubtedly greater than 55 per cent.

The eradication of oral foci of infection, with the exception of gingivitis and the earlier stages of pyorrhœa—or at least those which have failed to respond to proper attempts at treatment—falls entirely within the domain of surgery. And if, from my experience, I have reached one single definite conclusion it is that the usual "pulling" of these teeth is contraindicated. The operation of choice is surgical removal described by Novitzky,[6] which consists of the laying back of a proper flap over the bone so that it can be removed with a chisel sufficiently to expose the area involved or, at least, give proper access with specially devised curettes after the tooth has been lifted out, having proper regard to the prime importance of minimizing trauma and reducing to a minimum, consistent with thorough work, the period of anæsthesia. At the same time we must realize that the great value of the work lies in the opportunity of painstakingly searching out every bit of pathological tissue possible. By this means only, have we reasonable hope for attaining such an object, inasmuch as only by this method, after the tooth has been removed, is it possible to control the hemorrhage and carefully explore the bone under direct vision. All rough edges are carefully smoothed, the flap trimmed as may be necessary and sutured into place. The wound heals more rapidly than is usual when teeth are just pulled. Of course, circumstances may arise when it is not advisable to suture but to pack. The operator will be governed by his judgment.

"Pulling" teeth fails because, of course, it does not remove the infection in the bone beyond the tooth itself. Attempts at currettement down the socket are mere guesswork, even when straight-rooted teeth are pulled. When the roots are tortuous, it becomes a physical impossibility to reach clear to the bottom of the socket. Furthermore, the areas of infection in bone do not occur, according to regular pattern. They may extend at right angles to the socket, absolutely precluding access unless the superimposed bone is removed. As a matter of fact, blind curettement down a socket is rather more apt merely to stir up the infection, to shove it deeper into what may have been healthy tissue and make a bad matter worse. Pulling teeth violates one of the very fundamentals of bone surgery in that it establishes a dead

space into which three times a day is forced food detritus and broken-down blood clots.

When teeth have been affected with pyorrhœa for any length of time, the adjacent soft tissue is infected no less than the tooth itself and the bone. The mere "pulling" of such a tooth would in no degree whatsoever remove this tissue where it is no uncommon thing to find a granulomatous condition, which is very slow indeed in being thrown off by the body. And there invariably results more resorption of the underlying bone than would have occurred had all the pathological tissue been removed with the teeth—so much so that the gums and bony ridges are left in a very much worse condition for the retention of a prosthesis. Indeed, when it becomes necessary to remove all of the remaining teeth, surgical removal and a proper shaping of the bony arch and soft tissues—in short, plastic surgery, will play a very important part in the success or failure of the artificial restoration. Just exactly as the proper shaping of the bone to receive the pad of flesh under the flap of skin largely governs the success with which a wooden leg will be worn.

In conclusion, it seems hardly necessary to add that it is ridiculous to speak dogmatically. The mere presence of a dead tooth is not sufficient indication for its removal, and mere pulling may be proper under certain conditions. Complete histories of the patient are imperative, wherefor the active and sympathetic co-operation of the physician is indispensable.

A FALSE RUMOR

This office is amazed to discover that a rumor is prevalent that members of the Indemnity Defense Fund have been assessed $30 a year since the institution of the fund in December, 1916. This is not true. The first assessment on Fund Members will be levied this year. Those who joined it at its inauguration have had the benefit of its protection for five years without assessment of any kind for that period.

Payment of $15 in cash and the execution of a note in the sum of $15 due one year after date entitles any member in good standing to join the fund.

SOME CLINICAL ASPECTS OF PNEUMONIA*

By HENRY H. LISSNER, M. D., F. A. C. P., Los Angeles

The purpose of this paper is to discuss certain clinical impressions which were gained during the influenza epidemic from observation of over one thousand cases of pneumonia.

At the beginning of the influenza epidemic the pneumonia cases were not numerous, but as the infection increased in virulence pneumonia was present in greater numbers. We found that pneumonia developed in three different ways: (1) During the course of influenza, after the second or third day; (2) at the end of the disease, four or five days after the fever began to subside; (3) after the temperature had been normal for a few days and the patient was apparently convalescent, a sudden rise of fever and chill, with marked depression, presaged the development of pneumonia.

The most striking objective symptom of the transition from simple influenza to the pneumonia complication was the change in color of the patient. The erythematous flush of the face, neck and upper part of the thorax changed to a bluish or deep purple cyanosis, which involved not only the face and upper extremities but, in some instances, the lower extremities as well. This type of cyanosis was usually due to pneumococcic infection. Streptococcic pneumonia changed this erythema to a pale yellow waxy skin with blanched lips and finger-nails, or a color resembling muddy water, and was accompanied by profound asthenia. This change in color was obvious in pneumonia patients before the change in pulse and respiratory rate were manifest, and before definite physical signs were present.

There were no accurate means at hand by which the differentiation of the different types of pneumonia could be made clinically. It was evident very early in the epidemic that the usual physical signs of pneumonia were insufficient to cope with the multiplicity of the lesions, and that not infrequently lobar and broncho-pneumonia occurred simultaneously in the same individual. We were fortunate to have with us the Pneumonia Commission, sent by the Surgeon-General's Office and headed by Dr. Eugene Opie, so that we could follow to the post-mortem room a great many of the patients seen clinically.

A striking feature of the pneumonias was that usually two and sometimes three lobes were involved without definite distribution in either lung.

This multiplicity of infected areas made the diagnosis of the type of pneumonia difficult, accounting, in part, for the errors in diagnosis noted in the report of the Pneumonia Commission that "erroneous diagnosis of lobar pneumonia was made in 36.6 per cent of 227 fatal cases with autopsy."

Furthermore, it is my belief that many of the discrepancies between clinical and post-mortem

* Read before the San Francisco County Medical Society.

diagnoses were due in a large part to rapid examinations and hasty conclusions. It is also impossible always to make an accurate clinical diagnosis, even with the most careful examination and backed by laboratory and X-ray aid. These situations demanded extra effort to find methods by which lobar pneumonia could be more certainly differentiated from bronchopneumonia. The whispered voice sound, as reported in 1919, has been of greater value in this respect than any of the previously known objective signs of pneumonia. This sign is fairly accurate in the differential diagnosis between lobar and bronchopneumonia, except in cases of confluent bronchopneumonia, when it also fails.

From my observation of numerous cases seen clinically and followed to autopsy, I was impressed by the utter hopelessness of attempting to make a pathological diagnosis upon clinical findings. One has but to read the opinion of Opie in this respect to realize the handicap with which the clinician approaches this task.

"A diagnosis of suppurative pneumonia is rarely if ever made. The difficulties of diagnosis are in part explained by the frequent association of lobar pneumonia, with purulent bronchitis, with bronchopneumonia, or with both, and by the occurrence of bronchopneumonia with confluent lobular consolidation involving a large part of a lobe or whole lobes.

"There are many defects in the present knowledge of the symptomatology of pneumonias under consideration. Many of these deficiencies might be supplied by the time-honored method of comparing the clinical course of the disease with the changes found at autopsies, supplemented by bacteriologic studies made during life and confirmed after death."

These observations should be taken as a stimulus to the development of a clinical diagnostic acumen, which will keep abreast with the bacteriologic and pathologic progress of our knowledge of these acute respiratory diseases.

There are two types of pneumonia seen by the clinician that are important; the one from the diagnostic standpoint, and the other from the immunologic.

The first is the so-called central pneumonia. The frank pneumonias, whether of the lobar or broncho-pneumonic type, never presented any serious difficulty so far as the question of pneumonia was concerned, but in the central pneumonias diagnosis was much more obscure. Given a case of influenza in which the fever would not subside in the usual number of days, with slight increase in the pulse and respiratory rate, with the development of cyanosis, a few rales but no bronchial breathing heard and no dullness elicited, in all probability a central pneumonia is present. In this type there are three valuable diagnostic aids: First, the development of cyanosis; second, the transmission of the whispered voice sound over the consolidated area; and third, the X-ray findings. Central pneumonia is met with much more frequently than was formerly supposed. Many of the cases go unrecognized, because of the usual lack of clinical evidence upon which to base a diagnosis. In private practice, as well as in army practice, I am sure each of us can recall many cases with cough, fever, rusty sputum, etc., in which the physical signs of pneumonia were not found, and still we felt confident of the existence of consolidation. These cases usually ran their course as central pneumonias, the pneumonic process never reaching the periphery of the lung, and were most frequently observed in the lower lobes. A careful ring-to-ring examination, with the use of the whispered voice, will generally locate the consolidated patch of the lung responsible for the symptoms. It will also differentiate between the presence of a walled-off effusion or empyema, where the shadow in the X-ray is not definite.

The second questionable pneumonia is the abortive type, which is rare.

The fear of superimposed infection is important, as the report of the commission shows that "other types of pneumococci than those primarily responsible for the development of pneumonia occurred not infrequently in a certain group of cases, either during the course of the disease or shortly after the recovery from the first attack of pneumonia. Contact infection with different types of pneumococci were directly due to infection from patients in neighboring beds. In a similar manner, superimposed infection with streptococcus hemolyticus occurred at some time during the course of pneumonia with decidedly fatal results."

The clinical significance of such data must at once be obvious. It is invaluable so far as the grouping of cases in hospitals is concerned, but the knowledge gained is particularly applicable to the care and protection of the pneumonia patient in civilian practice. The time has passed when the clinician should take an indifferent attitude toward the dangers of undue exposure to certain forms of acute infectious diseases which involve the respiratory passages. We need only to hark back to our experiences not only with the past pneumonia epidemic, but influenza and measles are fast making themselves felt by their dangerous sequellæ, and are commanding increased clinical respect. Post-measles and influenza myocarditis are not at all infrequently met with in private practice, and clinical findings verified by X-ray have thrown considerable light upon the effect of these diseases on the lungs. It behooves the physician to use every means at his command to prevent contact infection, either in the hospital ward or the sick-room, and the ways and means adopted by the army proved most efficacious after they were once put into force. These methods are well known and will not be repeated here.

In the private sick-room the protection of the patient does not present the same problems. More complete isolation is undoubtedly possible and should be insisted upon by the attending physician. There is no way of knowing, except by bacteriologic study, if the patient has contracted a second infection after his crisis is delayed beyond the expected period. Not enough physicians in private practice have their pneumonia cases typed, and if they have such a study made once at the time of establishing the diagnosis of pneumonia,

in the face of prolonged fever, too few make a second bacteriological study to determine whether or not a secondary contact infection has occurred.

In discussing secondary infection, Opie states:

"Pneumonia cannot be regarded as one disease, but must be looked upon as a group of different diseases, with more or less similar physical signs and symptoms, it is true, but caused by a considerable variety of bacteria, infection with any one of which not only provides no protection against infection with another, but even may render the individual more susceptible to secondary infection." . . .

The fact that secondary infection is possible must of necessity revolutionize all of our previous knowledge of pneumonia, particularly from the standpoint of immunology, and must arouse in us a sense of clinical asepsis which in every way should equal the care with which a surgeon approaches an operation.

CONCLUSIONS

To sum up briefly the clinical lessons gleaned from this epidemic, I would say:

1. Cyanosis is one of the earliest objective signs of a pneumonic complication in influenza.

2. Prevention of contact infection should be sought in every case of pneumonia, with attention to early isolation.

3. Primary infection of either upper lobe is not as infrequent as was previously supposed; right middle lobe involvement is not common.

4. The pneumonia problem of the future should be looked at from the standpoint of preventive medicine and should be made a part of the problem of public health service as much as any of the other epidemic diseases.

UNUSUAL COMPLICATIONS IN A CASE OF MIDDLE EAR INFECTION *

By ISAAC H. JONES, M. D., Los Angeles

This case report is made because it presents many unique features, and sheds some light on the problem of surgical treatment of tympano-mastoid infection, associated with labyrinth irritation. I feel that if a similar case presents itself in the future, we would handle it in the same way, but we want to emphasize that such a combination of phenomena is rarely seen, and that the treatment and handling of this case, is not to be regarded as the way to handle an average case of tympano-mastoid infection.

Briefly, the case presented an apparently mild otitis media, violent labyrinth irritation, and a very large post-auricular abscess. The superficial abscess was drained, but the internal ear region was left strictly alone—a mastoid operation was *not* done. We thought it wise to wait, although, of course, we stood ready to open the mastoid if anything occurred to suggest its necessity. This very thing happened two months later—at which time the patient began to have disquieting symptoms, and the X-ray showed unquestioned involvement of the mastoid. Mastoid operation was then advised as being the safer procedure, although it was explained to the patient that there was a possibility of spontaneous recovery. The family preferred not to have the operation; fortunately, the patient made a satisfactory recovery. A careful examination made three days ago shows normal middle ear, normal cochlea, and a complete absence of all irritative symptoms—a fact the patient is entirely well, except for a diminution of function of the vestibular portion of the labyrinth.

The patient is a male, age 33, who has enjoyed good health; is of good mentality, and has unusual ability as an organist. He served in Royal Air Force in Canada, and had not previously suffered from dizziness, staggering, deafness or tinnitus.

In November, 1920, the patient contracted an acute nasal infection, following sea bathing. He used salt water douches, "trying to dislodge what was in the nose." This caused right earache, for which he consulted a doctor, who suggested opening the drumhead. This was not permitted, so nasal and throat treatments were substituted. Had two treaments a week—for six weeks—then followed a period of six weeks without treatment, and practically without symptoms. Then a recrudescence of ear symptoms occurred, for which he again consulted the doctor, who removed polyps from left naris.

On December 8, 1920, Dr. von Wedelstaedt noted a mild congestion of the right middle ear. The patient felt a bit dizzy while at the doctor's office, and then went to the theater. It was thirty minutes after that the attack occurred.

* Read before the Fiftieth Annual Meeting of the Medical Society of the State of California, Coronado, May, 1921.

As he was playing the organ, he began to notice that he could not turn his eyes to the left; (it was necessary for him to look to the left in order to see the moving pictures, and synchronize the themes of his music with the portion of the picture being shown). He found that he could turn his entire head to the left and watch the pictures, but that he could not turn his eyes toward the left without being made violently dizzy. He managed to play for the entire thirty minutes expected of him, and then suddenly he was seized with violent vertigo and fell to the left, pitching from the organ seat down into the organ pit, where he lay for one hour and a quarter, with six attacks of nausea and vomiting, vertigo and inability to move. He was found in this condition—entirely conscious, however.

During attack:

1. External objects all whirled from his left to his right.

2. He could not look to the left without becoming more violently seasick.

3. The falling tendency was entirely to the left.

4. In the organ pit, he found some comfort by lying on the right side, and stated, "If I rolled over on my back or on my left side, it brought on seasickness."

In analyzing this, it would seem that he had a pull of the eyes to the right, and that he was more comfortable when his eyes were kept in this position toward the right. Dr. Hiller took him home, at Dr. von Wedelstaedt's request, and put him on his right side. During the night, he tried to turn to the left side and vomited each time. He once tried to turn on his back, and immediately vomited. If he tried to walk, he fell forward. Each time he got on his feet, the room would whirl from his left to his right. He continued to vomit off and on for three days. On the fourth day, he was able to retain a little food, and he found that he could then lie on his left side without getting sick. On this fourth day, Dr. von Wedelstaedt felt it wise to do a paracentesis of right drum membrane, although no pus was forthcoming. The patient had been noting a rather mild earache, and on the fifth day he began to have "an entirely different kind of an earache," caused by a quickly appearing post-auricular swelling. At this time, Dr. von Wedelstaedt referred the patient for consultation.

Examination, December 17, nine days after the attack, revealed a curious otoscopic picture: the drum membrane showed some middle ear involvement, but the most noticeable thing was a good-sized mass, in the center of which was a pouting granulation situated distinctly external to the drum membrane, and on the posterior inferior wall of the external canal. Pneumatic suction caused the drum membrane to move, but failed to affect the contour of this mass.

Incision caused this external mass to subside within twenty-four hours; no swelling of the posterior superior wall, and the day following, the drum membrane looked almost normal. It was considered possible that the large post-auricular abscess had been produced through the external canal and not through mastoid involvement. Hearing was somewhat impaired in right ear, but bone conduction was greater than normal, and Weber lateralized to affected side (right); conversational voice well heard, and whispered sibilants at three feet; both cochleas normal. Caloric test showed marked impairment of responses from right ear. This, at first, made us think that the right vestibular function was impaired; however, the turning tests produced an unusually large and prolonged nystagmus, equally after turning to the right and to the left, and demonstrated that the internal ear was not only normal but somewhat hyperactive. We considered that the impaired responses to douching could be accounted for, in that the mass in the external canal and the moderate thickening of the drum membrane together might have prevented the cooling effect from reaching the internal ear. Incidentally, it is sometimes asked why the caloric test might not make the turning test unnecessary. This data given above shows the wisdom of performing every test whatsoever that could give any information in such a serious case. If we had relied upon the douching test alone, we would surely have drawn a wrong conclusion, and would have probably concluded that the internal ear was probably becoming purulent, even though the cochlea was normal.

Summarizing — Cochlea normal, and turning showed functionating vestibular portion. The internal ear was evidently intact, in both cochlear and vestibular portions; the middle ear showed little evidence of activity; the mastoid region showed large post-auricular swelling, but with no bulging of posterior superior wall. Because of the recent labyrinth symptoms, and the danger of disturbing the quiescent state of the labyrinth, it was decided to do an exploratory operation. Under local anæsthesia, a postauricular incision was made, evacuating a large quantity of pus. The periosteum was then incised and laid back, exposing normal bone. This is all that was done. It was decided for the present to defer mastoid operation. The patient made a good immediate recovery. Two weeks later, while at a theater, he had headache, and could not walk in a straight line.

January 16, paracentesis, after which staggering gradually lessened, although he noted that external objects appeared to jump up and down.

February 1, while playing the organ, sharp pain on top of head lasting a few seconds; suddenly there was "a click in the head, as if something had snapped"; after this the sharp pain ceased, and there was a burning sensation on top of head. The next morning, on looking to the right, everything stationary; on looking to the left, objects seemed to move up and down.

February 3, again objects jumped up and down, when looking to the left. While walking with a friend on his left side, patient was continually bumping into him; sensation of pressure in back of head (lower occipital region); unable to sleep

and tossed around in bed. Mastoid operation was suggested to patient, but was refused. About one o'clock in the morning, patient "began to feel shaky" and right arm began to shake; after two or three minutes the legs commenced to shake. There had been at no time any nausea, vomiting or sweating. Since February 1, soreness and throbbing behind the right ear; on February 4, throbbing had disappeared, but soreness remained.

Neurologic examination by Dr. Samuel D. Ingham—"Face flushed, expression anxious; eyeballs unsteady, but no definite nystagmus, even on lateral deviation, when subjective vertical movement of objects occurred. Station good and on each foot separately—eyes open and closed—no motor cranial paralysis. Tendon reflexes in arms and legs somewhat excitable."

Eye examination by Dr. E. R. Lewis showed probable nonpathologic tortuosity of the veins. Margins of discs were not obscure.

February 5—Fistula test markedly positive. Pressure upon the drum membrane, which is entirely intact, produced a sustained rotary movement of the eyes to the left; no horizontal movement whatever; and no quick component. This air pressure also produced a subjective sensation of falling to the left, and also a subjective sensation of external objects moving upward and to the left.

Galvanic Test—Anode and kathode gave normal responses from both ears—five milliamperes—suggesting intact internal ears; in fact, there was a rather better response from the affected ear than from the other.

X-ray Examination by Dr. William Bowman—"Cells of right mastoid appear to be filled with fluid or pus, and a portion of the cell walls is destroyed at the point indicated by an arrow on the plate. Another plate was made for the purpose of checking these findings, and again the mastoid region showed marked pathologic changes, with cell destruction in the mastoid region."

The patient was willing and rather anxious to have the mastoid opened, but the family persuaded him not to have any operation. For two weeks the patient had symptoms of pain and headache, and then all discomfort disappeared. He has been perfectly well ever since—three months.

Examination right now, May 9, shows normal drum-membrane, apparently normal middle ear and perfect hearing. In fact the patient could be considered to be quite unaffected by his illness except—

1. There is a striking reduction of vestibular function, evidenced by reduction of after-turning nystagmus from 34 and 34 to 17 and 13.

2. The rather unique exenteration of mastoid cavity shown by X-ray. Dr. Bowman's report: "At a former examination the mastoid cells were murky and indistinct, but while a portion of the trabeculæ had been destroyed, there were still some mastoid cells left in the lower-half of the mastoid. Now, the right mastoid region fails to reveal any evidence of any normal mastoid cells, the trabeculation having been entirely destroyed. The bone, however, is clear and shows no evidence of any necrotic area."

SUMMARY

1. We consider it quite possible that a mastoid operation, if done in the first place, might have resulted in stirring up a purulent labyrinthitis.

2. When later it became apparent that all was not well within the mastoid, it would have been safer to have opened the mastoid antrum, when we realize that the necrosis eventually not only exenterated the mastoid, but produced a fistula into the labyrinth; it is to be regarded as simply good fortune that the refusal of operation turned out as well as it did.

3. It is unwise to generalize about cases of labyrinth involvement, except to suggest that we should show hesitation in invading the region of the internal ear during an irritative attack, unless there is urgent necessity to drain an unquestionably purulent mastoiditis. Needless to say, the average case is that of definite purulent otitis, with involvement of the mastoid antrum, and in all such cases, of course, we should not only do a thorough paracentesis, but also open the mastoid antrum. This case, however, is not an average case and it impresses us that we must not generalize, but let each individual case be a law unto itself.

THE TREATMENT OF HUNNER'S ULCER OF THE BLADDER BY FULGURATION*

By HARRY A. R. KREUTZMANN, M. D., San Francisco

In 1914 Hunner reported in detail eight cases of bladder ulcer in women of a type, which previous to that time, had not been recognized. Due to the position of the ulcers and also to the fact that so little pathology is observed cystoscopically in contrast to the severe symptoms, this condition had previously been overlooked.

Nitze described a condition of the bladder-wall, which, no doubt, is the same as that presented by Hunner. However, the credit belongs definitely to Hunner for having emphasized this condition, and having brought it forcibly to the attention of the medical profession. Since his first paper this condition has been made familiar, and about seventy-six cases have been reported.

This type of ulcer has been given a number of different names. Cullen suggested "elusive ulcer of the bladder." Geraghty called it paracystitis; Keene named it circumscribed pan-mural ulcerative cystitis because all the coats of the bladder are involved. Bumpus considers submucous ulcer of the bladder appropriate, because of the great involvement of the submucousal structure. The term most commonly applied is Hunner's ulcer.

The etiology was not definitely known until Bumpus (1921) reported that he had produced

* Read before the St. Francis Hospital Clinical Group, October 28, 1921.

the typical bladder lesion in animals by the intravenous injection of pus-producing organisms, thereby strongly indicating an infectious etiology. The bladder urine is often sterile to culture, and many of the patients have no demonstrable focus of infection elsewhere in the body, nor do they have a clear history of any former infectious disease.

The pathological picture is that of a chronic inflammation involving all the coats of the bladder.

The predominating symptoms are pain and frequency of urination. The pain is of a sharp, stabbing character, usually occurring in the region of the bladder. However, it may be referred to the rectum, to the lower abdomen, to the perineum, or even to one hip. Stranguary, or burning on urination may be present.

The bladder walls are thickened and contracted, and the capacity greatly reduced. This may explain some of the symptoms. The pain occurs when the bladder becomes moderately distended and the rigid wall begins to expand under the pressure. Similarly, cystoscopy, especially with the water cystoscopes, is a most painful procedure and usually cannot be undertaken except under a general anæsthetic. Frequently the symptoms are of long duration, and many of the patients have had one or more major pelvic operations performed in an unsuccessful attempt to alleviate their suffering. In the first series of eight cases which Hunner reported, the average duration of symptoms was seventeen years. These ulcers are as common in men as in women.

The patients usually fail throughout their long illness to observe hæmaturia. Hunner states that very careful repeated microscopic examinations usually will show a few red blood cells and leucocytes. This minute bleeding occurs from breaks in the mucosa due to unusual stretching of the bladder-wall, either from overdistention or trauma.

Cystoscopic examination reveals very little, considering the intensity of the subjective symptoms. A thorough examination of the bladder reveals single or multiple ulcers, most frequently located at the vault or at the sides of the bladder and never in the region of the trigone, where Fenwick's ulcer usually is located.

When viewed with the water distention cystoscope, the ulcerated area has a glazed, dead-white appearance, from which the fine blood vessels have disappeared. Segments of blood vessels are seen coursing along the white area for a short distance, and then suddenly disappearing. Either in or near the edge of the dead area, single or multiple petechial spots, resembling the small reddish areas produced occasionally when the beak of the cystoscope traumatizes the bladder wall, may be seen. Small, wavy masses of fibrin may be attached to the edges of the ulcer.

A very characteristic phenomenon is noted, when the bladder is dilated beyond its pathological capacity. Immediately a fine stream of blood begins to flow from the ulcer and trickles down towards the base of the bladder. Very often the glazed, dead section is surrounded on all sides by an area of bullous edema.

All authors agree that the only treatment is excision of the diseased portion of the bladder. If a less dangerous procedure is available, in my estimation it should be given a fair trial before operation is attempted.

Following is the history of a patient treated successfully with fulguration alone.

CASE REPORT

B. M. Female; age, 46; no children, no miscarriages; venereal diseases denied. No history of tuberculosis, cancer, or insanity. Typhoid at six; pneumonia at twelve; no attacks of tonsilitis or peritonsillar abscess.

Present illness began in 1911, with frequency and urgency of urination. Dribbling during the day necessitated her wearing a napkin all the time. There was no dysuria or haematuria.

Various physicians had made diagnoses ranging from nervousness to "tumor." In 1912 patient noted that she had a constant sharp pain in the region of the bladder whenever she caught cold, but at no other time.

The patient states that she was operated upon in 1914 for "tumor." No tumor was found, but many intestinal adhesions were freed. There was no relief from symptoms, and the dribbling returned while the patient was still in bed.

During 1914 patient states that she was again operated upon for fibroid of the uterus. No fibroid was found; but the ovaries, tubes, and appendix were removed. Shortly after the second operation bladder pains developed similar to those she had previously suffered from whenever she caught cold. The pain was sharp and constant, radiating, at times, toward the perineum. When the pain was at its worst, the patient was compelled to stop whatever she was doing and remain perfectly immobile in a semi-bent position, with the left thigh flexed onto the abdomen.

Although she visited a number of physicians, complaining of frequency and great pain in the bladder, no cystoscopy was performed.

In 1919 the patient was referred to me by my father for urological examination. Urinalysis showed nothing abnormal. No red blood cells were found, but they may have been present and overlooked, as no special effort was made to identify them. Blood Wassermann was negative.

Cystoscopy under gas-oxygen revealed a whitish area on the left side of the bladder. Two small petechial spots were found above and to the left of the left ureteral orifice and on the edge of the dead area. While under observation and as the water was filling the bladder, suddenly a stream of blood began to flow from the two reddish areas towards the trigone. Urine cultures from the right kidney and the left kidney were sterile. No guinea-pig inoculation was made, but smears examined for acid-fast organisms were negative.

The diagnosis of Hunner's ulcer was made, and the patient was advised to have the diseased portion of the bladder resected. The patient refused operation. Bladder irrigations with silver nitrate were intolerable.

In April, 1920, fulguration of the bleeding areas was attempted. Due to a constant short in the electrical circuit, the trial was unsuccessful. She then went away to the country, hoping to benefit by absolute rest. On her return, her symptoms were unchanged. She still refused operation, but was finally persuaded to have fulguration performed the second time. The bleeding areas were deeply burnt until the hemorrhage stopped. The whitish area for a distance of one centimeter

about the ulcers was also fulgurated. The postoperative pain was controlled with morphine, and the patient left the hospital the next day.

Two weeks later the fulguration was repeated. She had some relief from the first sitting, and in less than a month after the second treatment her symptoms were entirely gone.

The patient has been under constant observation since that time. She voids four to five times during the day and once at night. She has been entirely free from pain throughout the past eight months.

Cystoscopy was performed the latter part of August, six months after treatment. The bladder capacity was 145 cc. The whitish area was still present. The reddened, ulcerated points had disappeared, and no bleeding occurred when the bladder was distended. It is of interest to note that there was no puckering of the mucosa, as one so often finds after fulguration of the interior of the bladder.

DISCUSSION

It may seem rather bold to say that the patient has been relieved by fulguration, in view of the fact that other physicians with large experiences have not had satisfactory results with this method of treatment.

In reviewing the literature, however, it appears that fulguration has not been given a sufficient trial to warrant its disuse. Hunner used fulguration twice in each of two different patients, and each time the patient was so much worse with pain that she refused to have it again.

Bransford Lewis used high frequency current in several of these ulcers, and found them exceedingly rebellious from every standpoint.

Buerger reported success with fulguration in one case characterized by excessive bleeding.

Fronz states that of twenty-six cases of Hunner's ulcer, which have occurred at the Brady Urological Clinic during the past five years, five were treated by fulguration. He concludes that this method of treatment is of value only in those cases in which there is a superficial involvement of the bladder wall and not where all the layers are affected; and that where possible, resection should be done in place of cauterization. None of the other authors have attempted fulguration.

CONCLUSION

The fact that this patient has remained well, though she, no doubt, had a severe lesion as was shown by our records, indicates that treatment by fulguration under an anæsthetic is warranted before the more severe operation of resection of the bladder is attempted.

(323 Geary Street)

PROGRAM OF STATE CONVENTION

The May number of the State Journal will contain the Official Program of our 1922 State Convention at Yosemite. There will be no separate program printed for this convention, so all delegates and other members of the State Medical Society who are going to attend our annual meeting are hereby informed and urged to bring the May number of the State Journal to Yosemite.

The May number will reach you in time to be read and then placed in your grip-sack as part of your necessary Convention Equipment.

THE RADICAL MASTOID OPERATION UNDER LOCAL ANAESTHESIA *

By H. B. GRAHAM, M. D., Shreve Bldg., San Francisco

For ten years it has been our practice to do mastoid operations in acute cases under local anaesthesia, this at the suggestion of Professor Heinrich Neumann of Vienna. The technic is simple, as there is no sensation in the bone, the skin and periosteum alone are desensitized. The customary one-quarter of morphine and one hundred-fiftieth of atropine having been given a half hour before the operation, a skin and periosteum infiltration of 2 per cent novocain solution is made, particular attention being paid to the external canal. The operation is then completed as usually performed, a sharp chisel being used and small, thin chips being removed with each blow of the hammer.

About two years ago I performed a radical mastoid exenteration by this method in a case of tuberculosis of the lungs where it was unwise to give a general anaesthetic, the bridge and small bones being removed under local anaesthesia and gas used for the middle-ear curettement and the plastic work.

Since then I have done two other tubercular cases; all of these have been very satisfactory and have been so much improved in their general condition that one was lead to suspect that the ear condition was responsible for their former lack of improvement. One case showed a quiescent lung condition but was coughing considerably and running a temperature of 99. After the operation the cough completely disappeared and the temperature remained normal, the patient being discharged in four weeks completely cured in respect to his ear and with arrested lung symptoms.

Another patient has shown marked improvement in her temperature and pulse chart and has lost an annoying cough.

That there are cases where the local anaesthetic is the one of choice is without question. Kidney and lung lesions may all be conserved by this method, and it is a question whether it would not be advisable to employ it in the majority of all adult cases. The entire operation has been done under local anaesthesia by Dr. Harold Hays, but I see no advantage in employing as much morphine, or 20 per cent cocaine, as he suggested and the whole operation is much simplified by resorting to five minutes gas at the end of the operation for the middle ear and plastic work.

The operations under local are slightly longer than under ether anaesthesia, as the chiseling must be done more cautiously, but none of these took more than one hour, and one was done in thirty minutes, so the patient is not under a very severe strain mentally or physically. As a rule a brisk conversation is conducted with the patient during the operation to distract his attention from his troubles.

* Read before the San Francisco County Medical Society.

PYELONEPHRITIS: A CRITICAL REVIEW OF 100 CASES *

By LT.-COM. O. C. FOOTE, M. C., U. S. N., San Pedro

This study is based on a critical review of one hundred cases of pyelonephritis, in which a complete urological investigation has been carried out. Pyelonephritis in children and infections occurring secondary to stone, urethral obstruction, prostatic obstruction, or in association with cerebrospinal syphilis, have not been included. This narrows the study, therefore, to the etiology of infections occurring in the kidney secondary to obstructions in the ureter, malpositions of the kidney, or malpositions of the pelvic organs in women, to the question of constant injury to the kidney as the result of gastro intestinal disturbances, and to the mere accidents of infection occurring here as may occur elsewhere in the body.

Sex—Sixty-nine per cent of the patients were females. This preponderance of females is not accidental and depends upon such factors as pregnancy, malpositions of the uterus and bladder, and infections of the bladder secondary to operative procedures on the pelvic organs. It was found necessary to recommend abortion in four cases of pyelonephritis incident to pregnancy because of extreme toxemia. In seventeen others infection had been firmly established at term, probably by long months of interference with urinary drainage from the kidneys. A few pyelograms have been made of pregnant women which showed considerable dilatation of the ureter. It would be interesting to know how constant a condition this is in pregnancy, and whether it may not be responsible, for infection of the kidney, and for other toxemias of pregnancy.

Pyelonephritis was associated with oöphorectomy in seven instances, hysterectomy in two instances, and with a suspension operation in one instance. Cystoscopic study of the bladder after hysterectomy shows intense congestion and, therefore, it is susceptible to infection and may properly be considered the focus of infection for secondary kidney involvement. Catheterization of the female bladder after pelvic operation has long been held responsible for the undoubted occurrence of infection; but if this is the mode by which infection is introduced, it is only because the bladder has been rendered extremely susceptible by injury, and it would seem that as a result of this hypersusceptibility, it might well become infected in other ways than by the introduction of the catheter. Suspension operations as a cause of pyelonephritis have not been sufficiently emphasized. During the slow descent of the uterus the patency of the ureter may be insured as it gradually assumes new positions and new relationships. When the uterus is lifted a considerable distance and put again into its normal position the ureter may be obstructed, and sufficient stasis may occur to result in infection.

It is therefore recommended that in pelvic procedures, which may result in trauma of the bladder, or in which the uterus is to be shifted in its position, the patient should be given, previous to operation, sufficient urotropin to secure prophylactic antisepsis of the urine.

Age—The following table shows the ages of patients on admission:

From	15	to 19	2
"	20	to 24	10
"	25	to 29	8
"	30	to 34	13
"	35	to 39	11
"	40	to 44	18
"	45	to 49	9
"	50	to 54	11
"	55	to 59	9
"	60	to 64	6
"	65	to 69	3

It is interesting to note how few infections were found to occur in youth. A number of cases of pyelonephritis in young children have come under observation, and pyelonephritis is known to be common in children. However, a study of these cases shows that pyelonephritis has two periods in which it is frequent: one in early childhood and the other in adult life. From this the interesting deduction is warranted that nephritis occurring in children, they must recover spontaneously in the large majority of cases. Not included in this series are three cases of pyelonephritis that have been encountered in childhood and which resulted in the death of one, and marked deterioration in health of the other two. In this type of case pelvic lavage should undoubtedly be carried out.

Types of Infection—The right kidney was infected in 18 and the left in 22 patients. In 60 the infection was bilateral. Eighty-four per cent of the patients showed a bacillus infection, and 16 per cent a coccus infection. Although we have not done sufficient bacteriological work to fully identify the organisms in all of the cases, most of these coccus infections showed more involvement of the bladder and were more frequently associated with surface ulceration and hematuria. These cases also were more resistant to treatment.

Pain—It is astonishing how severe an infection of the kidney may be present without pain of sufficient severity to cause distress. The large majority of the cases complain of only bladder disturbances, and it is the absence of pain in the renal regions which formerly led to so marked a chronicity in this type of infection. Eighty-nine of the cases in this group presented bladder symptoms, leaving a small percentage of eleven in which there were no urinary disturbances. Cases of severe infection of the kidney are sometimes subject to renal pain, usually aching in character, and which may be typically renal in distribution.

In other instances the pain in the back may be associated with pain in the upper abdomen or in the region of McBurney's point on the right side, and a corresponding position on the left side. There are still other instances in which infection of the kidney may be associated only with abdominal pain, and when this pain occurs in the region of the appendix it may be extremely difficult to differentiate between acute infection of the right kidney without appendicitis, and acute infection of the right kidney in association with appendi-

* Read before the Obstetrical Section of the Los Angeles County Medical Society.

citis. In either case there is fever, leukocytosis, pain in the region of McBurney's point, and in the actual absence of appendicitis we have observed a slight degree of rigidity and a tendency toward muscle spasm.

Urine—Ninety-five per cent of the cases showed pus in the urine. Sometimes even prolonged observation would show only an occasional pus cell, in spite of the large numbers of bacteria. The absence of pus in all cases of bacterurea has led some to the belief that one of the functions of the kidney is to excrete bacteria. When ureteral catheterized specimen of urine contains bacteria, the kidney is the seat of a definite infection. Prompt smear examination immediately after catheterization are necessary, because if examination is delayed it is impossible to be positive that the infection is in the kidney. The bacteria may be the result of contamination which has been picked up in passing the ureteral catheter through an infected bladder.

Direct slide smears are of more diagnostic value than cultures because cultures are nothing more than a multiplication many times of a misleading contamination. Also it must be remembered that all bacteria do not grow on ordinary laboratory media and many observations have failed to secure satisfactory cultures, even when direct slide smears showed a heavy infection of bacteria.

Macroscopically clear urine may be heavily laden with bacteria, and no urinary examination is of value unless freshly catheterized specimen in the female and freshly voided second-glass specimen in the male are immediately centrifuged and stained. Fifty-nine per cent of the cases showed blood in the urine. Albumen was present in 65 per cent of the cases, and infection was demonstrated in all of them.

Some cases of pyelonephritis have been found associated with parenchymatous nephritis in the same patient. In some of these cases exhaustive searches for focal infection, had been made, but a bacteriologic study of the urine had been neglected. It is possible that infection had occurred in association with a typical parenchymatous nephritis; but if this is the case, infection of the kidney would seem to have played a large part in the renal destruction, for in one of the cases showing a heavy cloud of albumin, the left kidney had been virtually destroyed, and the right reduced considerably in its functional capacity. The kidney itself should be more often considered as a source of its own focal infection, if focal infection bears any great relation to nephritis.

Other Considerations—The fact that pyelonephritis may be latent and is frequently associated with gastro-intestinal disturbances has led some to the belief that pyelonephritis may not be due to fault of the kidney but to constant invasion of the kidney by bacteria as a result of some type of intestinal stasis.

This theory is supported by the frequency of bilateral infection, but infection might well occur on the second side as a result of ascending infection. It is further supported by the frequency of gastro-intestinal disturbances in association with kidney infection, but in such diseases of the kidney as hydronephrosis, tumor, and stone unassociated with infection, it is not uncommon to find gastro-intestinal disturbances of a similar character. If kidney infection were often dependent upon gastro-intestinal stasis, local treatments of the kidney would not often prove successful, or lasting, and it may be that the persistent types of infection in which no stasis of the urine is demonstrated may depend upon constant injury to the kidney through intestinal stasis.

A good many cases of pyelonephritis are undoubtedly dependent upon stasis of the urine as a direct result of obstructions somewhere along the ureter, and dilatation of the ureter is of undoubted value in treating these particular conditions.

CONCLUSIONS

Pyelonephritis occurs more frequently in females than in males, due to pregnancy and gynecological procedures. Gynecological procedures should be preceded by the administration of urinary antiseptics, and these should be continued during convalescence.

Pyelonephritis is extremely common in childhood, is less frequent during youth, and again appears throughout life. From this it is concluded that the large majority of cases occurring in children spontaneously recover. There is an occasional case in which this does not occur and so lowers their resistance as to render them susceptible to other infections proving fatal. Children in whom pyelonephritis exists for a long period of time should be given the benefit of pelvic lavage. There is practically no difference between the right kidney and left kidney in incidence of infection.

Clinical observations of marked bladder disturbances and of infection of the urine subsequently followed by pain in the renal regions and fever have led to the conclusions that ascending infection may occur and probably often accounts for the bilateral nature of the disease.

Pyelonephritis is most often emphasized by bladder disturbances alone, but it may be associated with pain abdominal in type, and when associated with acute infection may be extremely difficult to differentiate from urinary infection associated with appendicitis. Not all cases of pyelonephritis show pus in the urine. Direct slide smears are of more value than cultures. There are infections of the urinary tract other than tuberculosis which, in the absence of urinary antiseptics, will not grow on ordinary media. It is not one of the functions of the kidney to excrete bacteria, and the finding of bacteria in kidney urine is evidence of a pathological process in that kidney. Chronic nephritis associated with infection of the kidney is not uncommon. The presence of large amounts of albumen in these cases has in some instances led to exhaustive studies of other portions of the body for foci of infection with total neglect of the kidney itself as a focus of infection.

Persistent cases of pyelonephritis in which no

stasis is present may have as their cause gastro-intestinal stasis. Pyelograms should be made in cases of persistent pyelonephritis to demonstrate the absence or presence of ureteral stricture.

I wish to express my grateful appreciation of the courtesy of Dr. Arthur B. Cecil, who has so kindly made the material for this study possible.

PERSONAL OBSERVATIONS ON UNUSUAL FORMS OF ACUTE POLIOMYELITIC PARALYSIS.*

With Remarks on Clinically Related Types of Epidemic Encephalitis and Landry's Paralysis

By WALTER F. SCHALLER, M. D., San Francisco

Wickman[1] has classified the following clinical forms of poliomyelitis:

1. The spinal poliomyelitis form.
2. The form resembling Landry's paralysis.
3. The bulbar or pontine.
4. The encephalitic.
5. The ataxic.
6. The polyneuritic (resembling neuritis).
7. The meningitic.
8. The abortive.

Weisenburg[2] in a study of 717 cases in the 1916 Philadelphia epidemic modified this classification as follows:

1. The spinal form.
2. The form resembling Landry's paralysis.
3. The pontine bulbar:
   - (a) Bulbar.
   - (b) Pontine.
   - (c) Pontine bulbar.
   - (d) Pontine spinal.
   - (e) Bulbar spinal.
   - (f) Pontine bulbar spinal.
4. Encephalitic.
5. Cerebellar.
6. Meningitic.
7. Abortive.

It will be seen that Weisenburg's classification differs more particularly in the subdivisions of the bulbar types and the omission of the so-called polyneuritic type. In fact, this author is convinced that the pain and tenderness in the affected limbs, which is so marked and characteristic of a certain group, is not at all of neuritic origin. He found at no time pressure over the nerve trunks producing pain. In favor of the view of the meningeal origin of these sensory disturbances is the rapid subsidence of pain following lumbar puncture. In fact, from the standpoint of therapy lumbar puncture was considered indicated and was done in every patient on admission to the hospital and was repeated as occasion arose according to meningeal symptoms and pain.

In the spinal types Weisenburg makes the point that the progression of the paralysis in both upper and lower limbs is from the proximal portions to the distal portions of the limbs. He makes the statement that there is no record of a single instance in which the paralysis started in the parts below the knee and extended upward. In the recession of the paralysis the distal portions cleared up more rapidly than the proximal. A more rapid improvement in the upper extremities took place when contrasted with the lower extremities. A Landry type is spoken of, but is not considered to be as distinct as is commonly supposed.

Wickman classified Landry's paralysis as a form of poliomyelitis. From a study of two unpublished cases of Landry's paralysis—one in which a necropsy was done and the spinal cord and peripheral nerves studied—it is my personal opinion that it is very doubtful whether this is the case.

Charles K. Mills[3] in 1910, studying an outbreak of poliomyelitis in the Lehigh Valley and Philadelphia of that year, mentions cases reported in Norway and Sweden and in this country showing lesions practically identical with those in the cord, also in the cortex and in the basal ganglions. He speaks of the so-called cerebello rubro-spinal symptomatology—coarse tremor with some paresis and rigidity; the whole somewhat like paralysis agitans, or a mixture of this disease and multiple sclerosis. Although on the lookout for this form, Dr. Mills had evidently not met with an example of it.

This brings up the question of the possible identity of epidemic infantile paralysis and epidemic encephalitis, which has been suspected because of the similarity of the histo-pathological picture. The fact that this latter disease has always been associated in epidemic form with influenza; that it is unusual for it to produce lower motor neuron paralysis and atrophies comparable to poliomyelitis; that adults are predominantly affected; that the seasonal prevalence is different; and that no corresponding increase in the number of cases of infantile paralysis occurred when the encephalitis epidemic was at its height: all these would speak against this identity.

Strauss,[4] Loewe and Hirshfeld claim to have demonstrated a filterable virus in epidemic encephalitis, to have cultivated it and by it to have reproduced the disease in animals.

Although morphologically this organism resembles that described by Flexner and Noguchi in poliomyelitis, it acts differently in its infectiousness in different animals, namely, in monkeys and rabbits. Strauss told me personally this summer that he believes that the virus of influenza and epidemic encephalitis are the same.

Thalhimer[5] confirms the above authors on the specificity of this organism.

Riley[6] and others before him have discussed the spinal forms of epidemic encephalitis. Such a classification may lead to the impression that this clinical picture of encephalitis, and poliomyelitis are similar. This has not, however, been my experience. In a study of some twenty-nine personal cases of epidemic encephalitis gotten together over a year ago, and read before the annual meeting of the Pacific Railway Surgeons, no example of a frankly similar picture to acute poliomyelitic paralysis occurred. Riley describes an irritative type and a paralytic type, this latter often being an end result of the former, and included as a type largely on theoretic grounds.

* Read before the San Francisco County Medical Society Meeting of November 1, 1921.

The irritative type is evidenced either by myoclonic or fibrillary contractions.

In the last number of the Archives of Neurology and Psychiatry (November, 1921) Morris and Jacobson [7] have written an excellent article on acute ascending myelitis of the infectious type, with necropsy findings in two cases. The literature on this type is reviewed; they do not feel that they can conclude definitely that these cases are due to infection by the poliomeylitic virus, although it is equally difficult to deny it.

It may be said, therefore, that there is definite proof lacking in the identity of acute poliomyelitis, epidemic encephalitis, and Landry's paralysis, although it still may be possible that they are different clinical expressions of the same disease. I note that in "Oxford Medicine" Peabody accepts as cause of poliomyelitis the organism of Flexner and Noguchi.

When we are dealing with cases of acute poliomyelitis the clinical forms are so variable that sometimes we are in doubt about the correctness of the diagnosis, particularly at the onset of the disease. I have recently met with two examples, both in adults, in which the first probability which occurred to my mind on seeing these patients was a transverse myelitis.

CASE REPORTS

Case I. F. G. E., male, age 21—Private Record No. 1801—Pre-paralytic onset of three days, commencing with weakness of the legs gradually increasing, and difficulty in starting flow of urine. No pain. Examination revealed a total flaccid paralysis of left lower extremity, and also of right lower extremity excepting some motion at the right ankle. A distended bladder extending almost to the umbilicus necessitated catheterization. Questionable hypesthesia below middle of thighs in both extremities. No disturbance of deep sensibility and no pain on deep pressure of muscles. A history of a penile sore, in spite of negative serological reactions, made it appear probable that this was a case of transverse myelitis on a syphilitic and endarteritic basis. Time showed the error of this view, as the paralysis remained a flaccid one; there never occurred any pathologic pyramidal tract signs; and there were no lasting sensibility disturbances. The muscles eventually showed frank atrophies and reaction of degeneration with tendency to recovery of function especially in the muscles of the right lower extremity.

Case II. B. G., male, age 34—Seen in consultation at the Southern Pacific Hospital, San Francisco, October 18, 1921. Pre-paralytic onset as follows: Eleven days before the paralysis violent pains on both sides of chest, accompanied by slight chill and a temperature of 103° F., made probable a diagnosis of pleurisy or pneumonia. Two days later the temperature fell to normal and the pain disappeared. Three days later the patient returned to his occupation and felt well with the exception of some pain in his chest on deep inspiration. Three days after return to work a return of pain, but at this time across the small of back, radiating down the anterior part of both thighs to the patellae. Pain was lancinating and intermittent and continued for three days. On the third day about 11 o'clock in the morning the patient was unable to cross his legs in bed, and this weakness progressed so that by 7 o'clock that evening he had no use of the lower extremities except to move the toes. The arms were not involved. The examination in consultation revealed a flaccid paraplegia with no discernible involvement of sensation. There was some pain on deep pressure of the affected muscles, but more so by stretching the muscles either by passive flexion or extension, and particularly by the Kernig maneuver. There was some motion left in the toes of both feet but no motion at the hips, knees or ankles. In this case, as the foregoing, patient was obliged to be catheterized twice after the onset of paralysis. This case is of such recent occurrence that marked atrophies have not yet developed.

Another clinical type which has interested me very much is the predominant type associated with distressing and continued pain in the affected muscles. We have investigated these cases by lumbar puncture to determine whether the meningeal reaction ran pari pasu with the subjective sensory disturbances.

Case III. R. C., male, age 18.—Stanford Dispensary No. 94194—Pre-paralytic symptomatology of nervousness, irritability, sleeplessness and diplopia following overwork. The paralysis of the extremities began in the left arm, extended to the left lower extremity, then to the right arm, and then to the right lower extremity. Whereas, objective sensation was quite normal in the affected extremities, the patient noticed from the beginning marked sensitiveness of the muscles especially on pressure. The examination showed a flaccid quadriplegia with hypotonia, areflexia and atrophy much more marked in the proximal than the distal parts of the extremities, although the patient was paralyzed to the extent that he could not assist himself or move from the supine position in bed.

The following were the lumbar puncture findings in this case under the following dates:

	Pressure	Leucocytes	Globulins
April 22, 1921.....	250 mm.	18.1 per cmm.	increased
April 26, 1921.....	?	33.7 "	"
May 2, 1921.....	180 mm.	10.9 "	"
May 11, 1921.....	85 mm.	23.1 "	"
May 18, 1921.....	150 mm.	10.9 "	"
May 24, 1921.....	.....	18.6 "	"
June 2, 1921.....	145 mm.	28.1 "	"
June 9, 1921.....	.....	126.8 "	"
June 23, 1921.....	140 mm.	10.6 "	"
July 5, 1921.....	70 mm.	8.1 "	"

Following the puncture of May 24, June 1, and June 9, mercurialized autogenous serum was injected in order to stimulate the leptomeninges to greater effort to overcome the apparent subacute infection of the subarachnoid spaces. When the patient left the hospital on July the 12th the pain in the muscles although less was still present.

Case IV. A. N., female, age 11—Stanford Dispensary No. 97459—Entered hospital with complaint of paralysis of both lower extremities from the hips down. Duration about two weeks. Prodromal symptoms of "growing pains" in the legs, especially in the calves, and some headaches; increasing pain in the legs and in the lumbar region, with chilly sensations. Two days after this onset fell in attempting to walk and afterwards inability to use the lower extremities. Immediately prior to the paralysis, sensation of numbness and tingling in the feet. Examination: Both lower limbs held flexed on the abdomen, and legs flexed on the thighs, with some motion in the right toes. Exquisite tenderness of muscles on manipulation; areflexia, hypo-tonicity. Sensation was unaffected. The examination was made exceedingly difficult on account of the great muscle tenderness. Active motion was very difficult to determine on this account, although the flexion posture of the limbs suggested that more active motion was possible than could be elicited.

A lumbar puncture on this patient done two days after admission showed a considerable in-

crease in the globulins and a leucocyte count of 11.8. On account of the faulty position of the lower extremities in flexion and the possibility of contractures, the orthopedic surgeons were called in consultation. On September the 1st, or about three weeks after patient was admitted, a lumbar puncture was done under great difficulty, the fluid being contaminated by an admixture of blood. There were but 10.5 leucocytes per cu. m. m. with some increase in the globulin, which might have been accounted for by the normal blood content of white cells. This count was, however, not satisfactory. This patient left the hospital after the last puncture and has not since been heard from.

Case V. S. R., male, age 3½—Stanford Dispensary No. 98753—Pre-paralytic symptoms lasting three days, commencing with headache and a temperature of 102° F. The fever fell on the second day, but the child was languid and rather stuporous. The third day he was unable to stand because of paralysis of the right leg. This was on September the 20th. Examination showed flaccid paralysis of the right leg in extension, the leg being externally rotated and the foot everted. The tendon reflexes of this extremity were not elicited. No evident objective sensory disturbances. The left leg showed no paralysis. A very striking feature of this case was pain and tenderness on passive motion or pressure of the affected leg muscles, and also of the left leg muscles, but to a considerably less extent. The spinal fluid examinations were as follows:

	Leucocytes	Globulin
September 23, 1921.....	32	positive
September 27, 1921.....	11.2	"
October 12, 1921.....	48	"
October 29, 1921.....	3.1	negative

When last seen (October the 29th) the power of flexion and extension of the right thigh was possible, but no motion was present at the knee or in the toes. The tenderness was decreasing but still present.

It occurred to us to seek some references regarding the spinal fluid content following acute poliomyelitic paralysis. Whereas Draper gives no data concerning the fluid after the first few days, Ruhrah and Mayer state that "cells disappear rapidly so that after two weeks the count is either normal or nearly so."

This is probably the case in most instances, but in our series the persistence of the fluid reactions most probably indicated a meningeal origin of pain in the third and fifth cases, the former showing an increase in the cells for more than two months, and the third not clearing until one month. Unfortunately, the most typical case of pain, or the second case, we were not able to thoroughly study from the standpoint of meningeal reactions.

STANFORD COLLOQUIA AT THE SAN FRANCISCO HOSPITAL

Surgical — (By Dr. Sterling Bunnell) — Our first patient is a middle-aged Mexican woman, with extensive tubercular enlargement of the cervical glands of all of the triangles in the left side of the neck. There is an especial enlarged one, probably with abscess, under the upper part of the sternocleidomastoid muscle. She noticed enlarged glands here for six years, though the greatest enlargement has taken place in the last month; this probably from abscess formation. Pathology of this degree is beyond cure by X-ray. I feel that X-ray and hygiene is the best treatment for beginning tubercular adenitis.

Surgery of this condition has gained ill repute because often merely the enlarged glands, and not the gland bearing tissue, has been removed from the neck. Considering this, it is not at all surprising that recurrent cervical enlargements are so frequent after operative removal. It is my conviction that the proper way to remove the glands and gland bearing tissue is en bloc, just as we do for carcinoma. It has been my experience that whenever the whole tubercular gland bearing mass has been removed in one piece, without tearing the tissue and spreading the germs about, that that patient has been cured, providing that the tonsils are removed and that there is no other tubercular focus. In such cases I have never seen local recurrence. A block dissection was then done and because of the magnitude of the operation it was followed by a transfusion of 900 cc. of blood. This reduced the pulse from 140 to 90.

The next patient is a woman forty years of age and very fat, who has had typical attacks of gall stones for six years. The present attack has lasted a week and was accompanied by a temperature of 101. About the lower part of the abdomen is a huge roll of fat, which suggests the necessity for a lipectomy, but peculiarly enough the layer of free peritoneal fat is as scanty as in a thin person. This, together with the finding of an infantile uterus, suggests hypopituritarism. The gallbladder is somewhat enlarged and congested, slightly thicker walled and more gray than normally and adherent to the neighboring viscera. The surface of the liver in the immediate vicinity shows a ribbing of scar tissue and along the cystic duct and common duct can be felt several enlarged glands. The pancreas is slightly harder than normal. Many stones can be felt in the gallbladder. In this case we have a full set of signs of cholecystitis. Quite often, however, we have a good history of cholecystitis and no gross signs in the gallbladder, except perhaps the enlargement of the telltale gland along the cystic duct. In such a case it is best to be guided by the history and remove the gallbladder. . . .

Our next case is that of an injury to the knee joint, caused by sitting upon it with the leg in the abducted position. There is local tenderness over the internal lateral ligament and pain is produced when the leg is abducted. There is also a greater degree of lateral motion in the injured leg compared with her normal leg. It

is, therefore, concluded that there has been a rupture of some of the fibers of the internal lateral ligament. This ligament is uncovered through a semilunar incision and a longitudinal incision is made through it. Through a small hole in the capsule of the joint the internal articular cartilage is explored and found to be normal. For a distance of about two centimeters the fibers of the internal lateral ligament are seen to have been torn. A strip of fascia is taken from the fascia lata of the same leg and transplanted under the internal lateral ligament, contacting with the tibia below and the femur above and the incisions are repaired. The free fascial graft, together with the resulting reaction in the surrounding ligamentous tissues, will result in so re-enforcing the internal lateral ligament as to effect a cure. This principle can be applied to a chronically spraining ankle. Fascia and ligaments are the safest tissues to graft and will live even when but one surface is contacted with vascular tissue.

Obstetrical and Gynecological—(By F. R. Girard)—Ovarian transplants: The patient before us is a gravida IV para II, thirty years old. Menstruation of the normal thirty-day type of four to five days' duration began at 14. Since an abortion, six years ago, menstruation has been every three to five weeks, accompanied by severe pain in both lower quadrants, down thighs and associated with backache. Vaginal examination shows no evidence of inflammatory disease; a small cervix with bilateral lacerations. The uterus normal in size, position, outline and consistency, but motion is limited by adherent adnexa to lateral pelvic walls. Operation shows both adnexa buried in dense adhesions to lateral walls and floor of the pelvis; left adnexa also adherent to sigmoid; posterior surface of cervix adherent to sigmoid; body of uterus normal; bilateral salpingo-oöphorectomy; blood supply of both ovaries badly damaged during enucleation and much raw surface on ovaries; bilateral hydrosalpinx.

Comment: A healthy uterus in a thirty-year-old patient makes this an ideal case for ovarian auto-transplantation. It is evident that these ovaries must be removed, and by removing the cystic areas from both ovaries and also the markedly thickened and sclerotic capsule we can place two grafts at the upper and lower angles of the incision in pockets prepared on top of the anterior rectus sheath.

Question—What are the chances of the grafts sloughing out?

Answer—By using multiple small grafts a much larger surface is obtained for establishment of new blood supply and by being careful to use ovaries which are not involved in acute inflammatory processes I have been able to secure grafts which have lived and functionated in all of the twenty cases of my experience.

Question—How long do you expect it to take before menstruation is re-established?

Answer—That varies with different patients. The shortest time from operation to first menstrual flow was five weeks and the longest time was six and a half months. Regarding length of time that patients menstruate after auto-grafting, my personal experience has been that cases grafted approximately two and a half years ago are still menstruating regularly and in a satisfactory manner. Professor Tuffier of Paris has, from a large series of cases, determined that the menstrual life after auto-grafts is approximately from two and a half to three and a half years. It is most gratifying to see the freedom from the distressing nervous, atrophic, nutritive and vaso-motor disturbances that these patients have when auto-transplantation has been done and menstruation preserved.

Medical Fees Under the Workmen's Compensation Act—It is believed that concrete examples of rulings upon medical fees may be of use to physicians in more ways than one. The following ruling in an actual case is furnished by Morton R. Gibbons, M. D., Medical Director, Industrial Accident Commission:

"My understanding is that your services involved a journey of 106 miles, being 53 miles one way; that the injury for which you attended the injured employe was a compound jagged fracture of the humerus three inches below the head, dislocation of the head of the humerus, and twelve small lacerations and four large lacerations, together with dangerous hemorrhage from many lacerated blood vessels. Your services included reduction of the fracture under anaesthesia and reduction of the dislocation; also the repair of twelve small wounds and four large wounds above mentioned; also ligation of several bleeding vessels. In addition to this there was the necessary treatment of shock, and application of retentive appliances.

According to the Fee Schedule you are entitled to fees as follows:

For reduction of the fracture of the humerus, compound	$ 60.00
Reduction of dislocation of the head of the humerus with complications	20.00
Repair of twelve small wounds	20.00
(N. B.—In multiple small wounds it is not logical to charge full fees for each.)	
Repair of four large wounds	20.00
(N. B.—It is noted that several of these wounds are of great extent, more than contemplated in the minimum of the Fee Schedule.)	
Mileage, 53 miles one way	39.75
For sutures, medicines and materials	2.70
This makes a total of	$162.45

A large latitude in judgment must be left to the surgeon who sees the case in emergency. If in his judgment, knowing his own facilities, his own skill and experience, and most of all, the needs of the patient, it would be better to treat him extensively without delay, he should certainly do so. Failure to perform the proper service at the proper time when it is possible to do so, entails danger of malpractice suit against the doctor, no matter whose rule he may be following or what employer's criticism he may incur later.

From the information which you give me and what I gather from your correspondence, it is my opinion that you did right in treating your injured man as you did."

The Hotel Casa Del Mar, near Venice, California, will be opened in a few days as a hospital of about 100 beds. William G. Lutz is superintendent.

The William H. Lewis Memorial Hospital has been opened at Atascadero, California. The hospital has 30 beds, including 12 private rooms. Charles A. Love, M. D., is director of the institution.

EDITORIALS

THE NOMENCLATURE OF DISEASES OF BONES AND JOINTS

The human mind, on recognizing an object, endeavors to put a name to it, and this is quite necessary in order that description and discussion may take place. Unfortunately, the mind has also a tendency to delude itself with the thought that investigation and exact knowledge may be avoided, provided an object be endowed with a name sufficiently scientific in its sound and all-embracing in its scope. Nomenclature, then, instead of being a help may become a hindrance, and the investigator may find himself hopelessly tangled in a net of ambiguous terms, which prevent him from making his meaning clear.

Diseases of bones and of joints well illustrate this point, probably on account of the obscure pathology of some of them. As the pathology of tuberculosis has become better understood, such terms as "caries sicca," "white swelling," and "scrofula" have slowly disappeared, but the nomenclature of the non-tuberculous arthritides is still so confusing that a reader is often quite unable to distinguish the meaning of the author he consults. What is arthritis deformans, osteoarthritis, rheumatoid arthritis, destructive arthritis, proliferative arthritis, degenerative arthritis, hypertrophic arthritis, atrophic arthritis, villous arthritis, metabolic arthritis? What is chronic rheumatism? The originator of each of these terms probably thought he knew what he meant by it, but how is anyone to guess at his meaning? Or how ascertain if he had any idea of the subject he was discussing? Osteoarthritis is, of course, an inflammation involving bone and joint, but its sponsor evidently does not wish us to attach that meaning to the term. Metabolic arthritis means everything and nothing. Villous arthritis is an arthritis characterized by the production of villi in the synovial membrane. The formation of villi is the reaction of the synovial membrane to any irritant, and is present in all forms of arthritis.

What is ankylosis? Let us ask a dozen medical men and tabulate their answers. Then let us attempt to define the various kinds of ankylosis, and again we are at sea.

A joint mouse has in our minds a fairly definite place, but to express our exact meaning is no easy task. The true joint mouse, as we well know, is found almost exclusively in the medial condyle of the adolescent femur. Some study is necessary to find out the exact reason for this, but the Germans avoided the difficulty by predicating a special disease for the condition and attaching to it the mouth-filling and awe-inspiring term, "osteochondritis dissecans." Accept the disease and the name, and no further investigation is necessary.

A very rare condition in the new-born is characterized by such a brittleness of the bones that they fracture easily and often. Call it "fragilitas ossium," and let it go at that. If we are still unsatisfied, change the Latin to Greek, and substitute "osteopsathyrosis idiopathica." If uttered glibly enough, this term will defy pursuit and will serve to quiet almost any class of students.

In 1903 Osgood and Schlatter discovered independently and almost simultaneously a peculiar condition of the tibial tubercle in the adolescent. In spite of the disadvantages of calling a disease after the name of its discoverer, until the nature of this affection is definitely determined, most of us are fain to name it Osgood-Schlatter disease. But lo! Certain ambitious observers think, after seeing two or three cases, that they have solved the problem and attempt to settle the matter by clapping on a name. According to all the rules of the game, Ebbinghaus must be right, for his title is almost as imposing as all the rest—"epiphysitis tibiæ dissecans traumatica adolescentium." Poulsen is a poor second with "periostitis tuberositas tibiæ," while Leclerc, Blencke and Kennedy trail far behind with "apophysitis tibiæ" and "acute epiphysitis."

Many examples might be multiplied to show the need of intensive study of bones and joints, in order to clear up the confusion. The pathologist and the clinician must work hand in hand, or better yet, one man must combine pathology with clinical medicine and surgery. As a preliminary to his study, let him decide on a definition of the active constituent of all bones—the marrow.

STOCK HOSPITAL PROPAGANDA

A second word of caution is issued upon this subject because, since our former editorial, some physicians have invested in hospital propositions that are bound to be failures. Physicians should require that new projects have the endorsement of their organizations before taking part in them.

Many of the various new activities that are springing up all over the State, and all over the country for that matter, are sound and deserve the fullest co-operation and support both in service and money. Other proposed hospitals, sanitariums, clinics, associations and what not are impracticable, visionary, unsound or dishonest. The records of many of the good, as well as the unsound propositions, are in the offices of your organizations. Investigate before you endorse any proposition with your moral support, service or money.

ARE YOU GOING TO ST. LOUIS?

Members of our Society, who intend to go to the A. M. A. meeting at St. Louis, from May 22 to 25, are requested to write to the Secretary of the Medical Society of the State of California regarding the matter of transportation and accommodations.

If 125 or more physicians wish to go from Yosemite to St. Louis we will be able to secure special accommodations and other attractions for our members. In order to have a census to present to the railroad company, it is urgently requested that you inform the State Secretary without delay of your intentions.

MORE ABOUT "ENDOCRINE GLANDS"

Doctor, have you read the book by Louis Berman, M. D., entitled "The Glands Regulating Personality: A Study of the Glands of Internal Secretion in Relation to the Types of Human Nature"? Have you read the extensive reviews of this book in the various magazines and newspapers? You should read them carefully and thoughtfully because thousands of people are reading them and you should be prepared to deal intelligently with those of your own patients who will need your services after such reading.

This book is a remarkably clever and attractive blending of known facts about an important and only partially understood subject with logical, illogical and visionary theories in such a way that the average reader accepts the whole thing as a fact.

Multitudes of readers will act upon the "knowledge" they obtain from this book and from its extensive reviews to "prolong" their lives, change their "personalities," restore their "lost vigor" or cure their diseases by purchasing and using these dangerous preparations now everywhere available, or by becoming patrons of some of the numerous advertising fake healers who already are reaping harvests from this field.

Publications about such subjects with more positive differentiation between fact and fancy are useful to physicians and other serious students, but they would have no great "news" value and no "publicity" or "propaganda" value under these circumstances.

Stories like the book in question are being issued about other unsolved questions of pathology, and no doubt more will be forthcoming. They do a great deal of harm of several varieties and little, if any, good in any way.

Of course, there are problems—great problems—bound up in the physiology, pathology, diagnosis and treatment of disturbances of the glands of internal secretion. There is and has been for many years an ever advancing chain of new knowledge being produced from many sources tending toward solution of the problems. All that is safe of this new knowledge is taken advantage of by physicians in the diagnosis and treatment of disease, and such progress, research, and practice should and will continue.

However, serious thinkers regret the introduction of literature which, whatever the intentions of the authors, tends to deceive the general public and lends itself so readily to the uses of propagandists and even unscrupulous persons for commercial purposes. This to the detriment both of legitimate science and of the public health.

OVERSPECIALIZATION IN PUBLIC HEALTH WORK

We are hearing and reading a lot about overspecialization in the practice of medicine and the importance of this development in the constantly increasing cost of medicine to the public.

We are not yet hearing so much about the vastly more important problem of the enormous cost of public health and public welfare and the more certain element of overspecialization in producing the excessive cost.

The generally recognized specialties in diagnosis and treatment of disease are less than ten. They are all in the hands of physicians. The specialties in "prevention" as now practiced and paid for range from twenty or more in rural communities to hundreds in some cities. Some of these are the legitimate medical and government agencies usually operated by physicians and other health officers of experience.

The array of so-called voluntary organizations is bewildering in their number, in their activities, in the changing and often doubtful quality of leadership and in the amount of money they spend.

The contributing public is becoming curious, and one of these days someone is going to take the trouble to find out how much money is collected, donated, levied by taxes and otherwise provided by the public for "welfare and health work"; they will show when, where and what for this money was used, and when that is done and published there is going to be a slump in organizations devoted to "uplift."

DANGERS IN EDUCATION

The dangers of government bureaucracy, politics and over-organization in education are emphasized in the annual report of the President of Columbia University just issued. We read:

"One of the most noteworthy of recent developments in American life is the zeal with which machinery is designed and built ostensibly to serve various public interests and undertakings, but in reality to control them. Perhaps in no other way is the decline of faith in liberty so clearly marked. . . .

"So far as education is concerned, this has been over-organized for a long time past. Too many persons are engaged in supervising, in inspecting and in recording the work of other persons. There is too much machinery, and in consequence a steady temptation to lay more stress upon the form of education than upon its content. Statistics displace scholarship. . . .

"It is now proposed to bureaucratize and to bring into uniformity the educational system of the whole United States, while making the most solemn assurance that nothing of the kind is intended. . . . If tax-supported education be first encouraged and inspected, and then little by little completely controlled, by central authority. European experience shows precisely what will happen. . . .

"The true path of advance in education is to be found in the direction of keeping the people's schools closely in touch with the people themselves. Bureaucrats and experts will speedily take the life out of even the best schools and reduce them to dried and mounted specimens of pedagogic fatuity. Unless the school is both the work and the pride of the community which it serves, it is nothing. . . .

"It is fortunate that Columbia University, a public institution, was founded and is supported by the State in the field of liberty, and that it is free to carry on its work beyond the reach of the deadening hand of government."

There is more in this report that every person interested in education should read.

STATE SOCIETY

ABSTRACTS FROM THE MINUTES OF THE ONE HUNDRED AND TWENTY-NINTH MEETING OF THE COUNCIL OF THE STATE MEDICAL SOCIETY.

(Held in Los Angeles, January 28, 1922.)

Industrial Accident Work—The report of the State Society's committee on Industrial Accident Insurance Work was considered by the Publicity Bureau, where a few minor changes in the report were suggested, and the matter in this shape came before the Council. Upon motion of Parkinson, on behalf of the committee, it was unanimously

RESOLVED, That the amended report, containing the modifications and changes suggested by the Publicity Bureau, stand on the minutes of the Council as the original report of the committee, this report being as follows:

REPORT OF COMMITTEE ON INDUSTRIAL ACCIDENT INSURANCE

Adoption of Blanks and Fee Schedule—The committee requests that it be authorized to hold conferences with insurance companies and with individual representatives of same, to secure the general adoption of the Society's blanks, which automatically adopts the fee schedule.

Increase in Fees—The committee believes conditions at present are inopportune for seeking an increase in the present fee schedule and recommends that action be deferred until prices have been stabilized and the business outlook improves.

Enlargement of the Panel—In line with its former suggestions, the committee believes steps should at once be taken to enlarge the panel. It recognizes that, while many physicians believe the injured employe should have the right to choose his medical attendant, this right cannot be conceded by those legally responsible for his care and legally liable for every expense attached thereto. At the same time there is no reason why men competent to do surgical work and to make the necessary reports should not be permitted to treat all cases referred to them by employers.

The question of professional competency is not based upon personal preference, nor can it with certainty be determined by a layman nor, indeed, by an insurance company not employing a medical director. The medical profession is the only judge of the qualifications of its members and their efficiency in the various specialties.

The committee therefore recommends that various County Societies be requested to assume this responsibility toward the State and that each Society be instructed to certify to the secretary of the State Society a list of its members competent by education, training, experience and licensure, to do the industrial surgery required in industrial accident insurance, willing to undertake this work and willing to make prompt and accurate reports of all cases. If a physician claims to be practicing any specialty exclusively, his specialty should be indicated, with his experience and qualifications as above mentioned.

It is recommended that the County Societies assume the responsibility not only of providing the State secretary with this original list, but of providing at least a monthly list showing changes in this panel.

No attempt should be made to indicate the manner in which any society shall reach its conclusions, nor is any machinery suggested for determining the result. It must, however, be understood that every society certifying a panel will stand sponsor for the accuracy of the statements given as to the men's education, training and other qualifications to do insurance work, and agrees to demand from them and extend to them the customary professional support and courtesies.

The committee believes that if this course be adopted by the County Societies it will result in better treatment for beneficiaries and a more equitable distribution of industrial medicine practice, and that carriers when assured of these facts will accept the plan.

JAMES H. PARKINSON,
JOHN H. GRAVES,
GAYLE G. MOSELEY.

Question of Laymen Contracting for Accident Insurance Work and Hiring Physicians to Do It—This matter being before the Council, it was unanimously resolved that the matter be investigated by the Publicity Bureau and reported upon at a subsequent meeting.

Program for 1922 Meeting—The secretary discussed the progress being made by the Program Committee and asked for approval or instruction upon a number of points, the only one requiring action being to the effect that the report of the Committee on Industrial Accident Insurance be presented at one of the general sessions by the chairman, James H. Parkinson, instead of before the House of Delegates only, as usual.

Action by the Council—Upon motion regularly moved and seconded, it was

RESOLVED, That the report be read to one of the general sessions, and that the House of Delegates be requested to recognize this as the official presentation of the report.

Rebates and Commissions—Communications in the hands of the secretary suggested that the Council reiterate its stand in interpretation of the ethics upon the problem. The following resolution was unanimously passed:

RESOLVED, That the Council believes that any agreements or understandings between members of this Society and pharmacists, whereby money or any other valuable consideration is paid to physicians in connection with their prescriptions, is unethical and derogatory to the medical profession. Further, that the writing of prescriptions by physicians on blanks furnished by druggists or bearing the names of druggists should be discouraged as open to misconception.

Convention Number of the State Journal—The Council approved the policy of making the May number of the State Journal the "Convention Number" and including the program therein instead of printing a separate program. They furthermore approved as a matter of policy the issuing of a daily Convention Bulletin under such conditions as may be brought about by the chairman of the Publicity Committee and the executive officers of the association.

Rules of Policy Regarding Publications in the Journal—The Publicity Bureau presented a number of rules upon this point. These rules were unanimously approved by the Council and are as follows:

1. The Journal will not publish original manuscripts except as presented by members of the State Society; provided, in the case of invited guests to the State Society or one of its constituent society meetings or invited guests to some special conference or meeting, they may be accepted at the discretion of the editor.

2. Except in special instances approved by the Publicity Bureau, manuscripts will not be accepted for publication in the Journal until they have been presented at a State Society meeting or a meeting of one of its constituent societies.

3. Manuscripts consisting essentially in individual case reports, unless these reports deal with extremely rare or unusual conditions, are not considered as being suitable for the Journal.

4. The editorial staff, as is usual in publications, shall reserve the right to modify, condense, extend or reject any manuscript from any person.

5. As a matter of policy, which may be changed only in special instances, the Journal will not accept articles of more than 5000 words and will give preference to those of from 2000 to 4000 words.

6. The Journal being intended to represent the entire membership of the State Society, the editor will, as far as feasible, give preference to material for publication that promises to be of the greatest good to all members of the profession.

7. In the selection and rejection of manuscript the editor and the Publicity Bureau will be guided in their action by the merit of the paper and to a limited degree by expediency. No discrimination will be made between the manuscript read at the State Society meeting and one read at any constituent society meeting. The determining point in both instances shall be the merit of the paper, and neither the Publicity Bureau nor the editor is obligated to publish any manuscript simply because it has been presented to either the State meeting or any other medical meeting.

8. The following information and rulings regarding articles for publication in the Journal are adopted with slight modifications from the A. M. A. "Style Book." This pamphlet of sixty-six pages, and which costs 25 cents, is a necessity to any medical author, and it is urgently recommended that physicians who read papers before medical societies or who write for publication secure and use this pamphlet:

Acceptable Paper—In order to be acceptable for the Journal, a paper must either (1) contain and establish positively new facts, modes of practice or principles of real value; (2) embody the results of well-advised, original researches, or (3) present so complete a review of the facts concerning any particular subject as to enable the writer to deduce therefrom legitimate, important conclusions. Our medical literature is loaded down with articles which do not come up to any of these specifications.

The Spoken and the Written Word—The requirements for a paper to be read before fifty or a hundred physicians are necessarily different from those for a paper to be published in a journal in which it may be read by thousands. Hearers will listen to a lengthy paper, even though it be rambling and discursive; readers of the same paper will impatiently turn the pages to the next article. Anyone can write a long paper, but presentation of facts concisely marks the experienced, careful writer. Every writer should realize this fact: the longer the paper, the fewer the readers.

Simplicity—Avoid (1) unnecessary, irrelevant or second-hand information; (2) needless references to literature; (3) extensive quotation; (4) elaborate language.

Carefulness—Hasty, careless composition is inexcusable.

A suitable title, suggestive subheads, a clear summary, and cogent conclusions represent the framework of a well-constructed paper.

The Right Title—Titles should be explicit and descriptive. They should be brief and definite.

Summary and Conclusions—The summary—the brief abstract of the article—may appear as an introduction or at the close; the conclusions—the deductions drawn from the cases, experiments or other facts set forth—appear always at the close. The value of the summary and conclusions is less appreciated by the average writer than by the average reader. The busy physician looks at the title to see if the subject interests him, glances at the subheads to see the phases considered, and then turns to the summary to get the gist of the article. The summary and conclusions will be reproduced by journals which otherwise would not take the trouble to abstract the article, thus presenting it to a larger circle of readers.

Negative Findings—Space should not be devoted to unimportant findings, or those which have no bearing on the subject under consideration. Negative findings are of value in few instances.

Exclusive Publication—Articles are accepted for publication on condition that they are contributed solely to this Journal.

Neatness—Illegibility, close spacing or other marked defects in the preparation of a manuscript, as well as errors in spelling, grammar or diction, give the impression that the research or observation embodied in the article is equally slipshod and inaccurate, and may turn the scale against its acceptance by the Journal.

Illustrations must illustrate; they should be clear, distinct pictures. To show instruments, apparatus, diagrams of operative technic, etc., drawings with pen and black ink on hard white paper are usually preferable to photographs.

Roentgenograms—Unless exceptionally clear and distinct, these are unsatisfactory. A roentgenogram which must be studied with much care in the original in order to find the significant points will probably show no details at all in the reproduction. When it is possible to use a diagram instead, this is frequently more graphic and hence more acceptable.

Character of Reproductions—The illustrations found in the Journal are known as "halftones" and "zinc etchings." A halftone can be made from any copy furnished, whether it is a photograph, a washdrawing or a linedrawing. Halftones are used almost exclusively in reproducing photographs and washdrawings. Zinc etchings are made from linedrawings. A zinc etching cannot be made from a photograph or from a washdrawing. Halftones require a "supercalendered" or "coated" paper; zinc etchings reproduce satisfactorily on soft or "machine-finished" paper.

Proof—Unless otherwise arranged in advance, proof of original articles is submitted to the author before publication.

SUMMARY

Plan your paper before you write it.

Make your title descriptive but brief.

Use subheads.

Number all pages consecutively.

Put your name on your manuscript and on each illustration.

Be brief.

Write in a simple, careful, grammatical style.

Delete all non-essential words, phrases, sentences and paragraphs.

Provide a summary if your article is long; give your conclusions if any were made as a result of your observations.

Verify the spelling of technical and unfamiliar words, and of all proper names.

Don't call the patient a case.

Don't copy a report of a case from the clinical record sheet. Tell the essential parts of the story in narrative style.

Send the original, not the carbon copy, to the publisher.

Fold, do not roll, manuscripts.

Manuscripts should be typewritten, double-spaced, on one side of the paper only.

Illustrations must illustrate.

Do not send negatives or glass slides. Send prints on glossy paper.

Number all illustrations consecutively.

Provide a legend for each illustration.

Write legends consecutively on a separate sheet of paper at the end of your manuscript.

Patient's consent must be secured to the reproduction of photographs.

Correct and return proof promptly.

Verify all facts and be careful to omit anything of a libelous nature, both in the written word and in the illustrations.

Junior Medical Societies for Medical Students—The question of forming Junior Medical Societies from among the members of the different medical schools of the State was discussed. The advantages of having these students operate their own medical society under the same constitution and by-laws that a regular medical society is operated under, insofar as this is feasible, were discussed, and it was felt that this should be of advantage to students in preparing them to take up the broader duties of citizenship after they have received their degrees. It is understood, of course, that such societies would have no authority whatever to take action binding on the medical profession, nor would they have power to represent the medical profession. It was suggested that there might be one unit society for each of the three medical schools in the State, made up exclusively of its student body, and that these societies recognize the advisory or censorship control of the Council of the State Medical Society.

Upon motion regularly made and seconded, it was resolved, that this matter be referred to the medical schools of the State of California, and that, if they approve as a matter of policy, the Council approve the general policy laid down and that the matter be referred to the Publicity Bureau with instructions to formulate rules and regulations.

Accredited Agencies and Other Accredited Representatives for the Journal—Applications to become accredited agencies for selling individual copies of the Journal and for securing subscriptions upon a commission basis being before the Publicity Bureau, it was voted by the Publicity Bureau to recommend to the Council that they approve a policy of establishing accredited agencies and recognizing accredited representatives for the Journal, the number of agencies and the conditions under which they work to be approved by the Publicity Bureau.

Action by the Council—Resolved, That the agencies should be established, the price to be charged them to be fixed by the Publicity Bureau.

Biographical Data on Members of Our Association—The question of obtaining biographical data of our members was brought up for discussion. It was recommended that in sending out the official membership cards to individual members, mailing facilities be taken advantage of by enclosing with this membership card a letter (form submitted) inviting our members to furnish biographical data for the files of the State office.

RESOLVED, That this recommendation be approved and the secretary be instructed to have a supply of these form letters printed.

New Licentiates in Medicine in California—The question was discussed of greeting new licentiates in California by sending each one a letter from the State office (for msubmitted) and asking them for biographical data.

RESOLVED, That the form letter be approved and the secretary instructed to have a supply printed, to be sent to all who are eligible for membership as soon as notice is received from the Board of Medical Examiners that they have been licensed in California.

Superintendent of Publications—Realizing the constantly increasing importance of the mechanical and typographical features of our State Journal and other publications, and in consideration of the splendid willingness of Mr. William H. Barry of The James H. Barry Company to aid and assist the Society in all of its work, upon motion it was

RESOLVED, That Mr. William H. Barry be appointed "Superintendent of Publications," his name to be carried on the Journal with the other members of the editorial staff; this appointment to be subject to control by the Publicity Bureau of all conditions and problems arising out of this arrangement, and to be without salary.

Reassignment of Editorial Pages in the Journal—The question of reassignment of editorial pages to the center of the Journal instead of the first pages as at present, was discussed. As it was felt that this would comply with the general usage in publications and as it would also aid materially in the mechanical work of the Journal, it was

RESOLVED, That the editorial pages should be assigned to the center of the Journal and the scientific articles should comprise the first pages.

Medical Advisory Committee—The secretary presented a circular letter from a "Medical Advisory Committee," Dr. F. H. McMechan, secretary, Avon Lake, Ohio. Upon motion it was

RESOLVED, That the Council lay this matter on the table and advise every county medical society in the State to do the same thing.

Question of Instructing Delegates to the American Medical Association—After discussion and upon motion regularly made and seconded, it was voted that the following resolution be introduced by the Council to the House of Delegates at the next annual meeting:

RESOLVED, By the House of Delegates of the Medical Society of the State of California, That it is the policy of this Society to instruct by resolution, either of the House of Delegates or of the Council, the delegates of this Society to the American Medical Association, on all matters of national concern upon which this Society either has or desires to institute a definite policy, or which in the opinion either of the Council or the House of Delegates peculiarly affects this Society.

Assessment on Indemnity Defense Fund Members—The fact was brought up that it will be necessary for the Council to take definite action in levying the assessment on all old members of the Indemnity Defense Fund in the sum of $5 for the year 1922 and for each year thereafter until otherwise ordered; provided, that the admission fee for new members shall remain at $30, in accordance with the authority conferred upon the Council by the House of Delegates at the 1921 meeting. Upon motion regularly moved and seconded, it was

RESOLVED, That the recommendation of our attorney that this matter be held over for consideration at the Yosemite meeting, be adopted.

Local Transportation in Yosemite—It was reported by the Publicity Bureau that the Yosemite Transportation Company has adequate facilities for

local transportation, but some means must be provided to pay the expenses of this transportation during the State meeting. The following methods were suggested: Shall the "street car" fare be a charge to all persons or only to those who do not have badges, or shall the Society in some other way arrange for these expenses, so that all persons may ride as they please without charge? After discussion and upon motion, it was

RESOLVED, That individuals riding shall pay their own fares.

Improved Service by State Society in the Problem of Industrial Medicine—All members of the Society realize the difficulties connected with the work under the Industrial Accident law; all members realize the necessity for the State Society's taking some responsibility toward great efficiency and harmony in the carrying out of this law. It is realized that the present finances and office force of the State Society will not permit of such necessary expansion. After due consideration, on motion regularly moved and seconded, it was

RESOLVED, That the secretary be empowered to employ additional help along the lines suggested by the attorney and himself, so that this industrial accident work may be properly co-ordinated with the other work of the Society.

Question of Responsibility for Section Programs—The secretary raised the question as to who is responsible for section programs. It was stated that in the opinion of the State Program Committee general programs should be filled by invitation from the Program Committee, and section officers should be, as far as possible, responsible for their own section programs, the State Program Committee assigning to each section the number and length of time of periods and the place of meeting of each section. Upon motion it was

RESOLVED, That, except for the fixing of the number, time, places and duration of section meetings, which is the duty of the General Program Committee, the responsibility for section programs is in the hands of section officers, and that the details of section programs are only supervisory as far as the secretary is concerned.

Membership in Local and State Societies as to Licentiate Requirements of the State—The constitution and by-laws as they now stand provide that only doctors of medicine from acceptable medical schools, who are licensed to practice medicine and surgery in the State of California, are eligible for active membership in county and State medical societies. This works a definite hardship in certain specific instances of highly trained men, usually engaged full time in some of the non-clinical branches of medicine, the detriment being equally shared by the Society. Because of the inadvisability of suggesting changes to the Medical Practice Act, it is recommended that the Council introduce at the next House of Delegates the following resolution, as an amendment to Article VII, Section 5, of the By-Laws:

RESOLVED, That the Council of the State Society be authorized to make exception to the existing State license requirement for active membership in local and State societies in specific instances and under such conditions as seem to them sufficient.

Rules Regarding Papers and Discussions at the State Meeting—It was voted by the Publicity Bureau that the following rules be submitted to the Council, with the recommendation Do Pass:

1. The maximum time that may be consumed by any paper is fifteen minutes, provided that not to exceed ten minutes latitude may be allowed invited guests at the discretion of the presiding chairman.

2. Motions from the floor to extend the time of an author may not be entertained by the presiding officer.

3. The maximum time permitted any individual discussant on any paper is four minutes. This also applies to the author in closing his discussion. No discussant may speak more than once upon the same subject.

4. A copy of each and every paper presented at the State meeting must be in the hands of the chairman or secretary of the section or in the hands of the general secretary before the paper is presented.

5. No paper will be accepted by the general program committee nor by a section program committee unless accompanied by a synopsis of not to exceed one hundred words.

6. Papers shall not be "read by title."

7. No member may present more than one paper at any one State meeting, provided that members may present additional papers before sections on technical specialties; and provided further, that a member may be a collaborator on more than one paper, if these papers are presented by different authors.

8. Failure on the part of an author to present a paper precludes acceptance of future papers from such author for a period of two years, unless the author explains to the satisfaction of the Publicity Bureau his inability to fulfil his obligation.

RESOLVED, by the Council, That the recommendation of the Publicity Bureau be approved.

Auditor's Reports and Financial Statement for the year 1921—The secretary and the attorney presented the auditor's report for the State Society and for the Indemnity Defense Fund and the Financial Statement of the office for the year 1921: Upon motion, it was,

RESOLVED, That these reports should be accepted and placed on file.

Cost of Hospital Care—Clipping bureaus show that cheap costs of operating a hospital and otherwise caring for the sick are still items of sufficient interest to call for prominent headlines. The clipping bureaus show many reports of hospitals that take great pride in caring for their sick people at from 75 cents to $1.50 a day. Any person, even the least bit familiar with the facts, or even the facts of what it costs well people to live, can appreciate something of the care that patients get in institutions of this kind.

Annual Meeting
State Society
May 15 to 18, 1922
Yosemite Valley

COUNTY SOCIETIES

Alameda County Medical Society (reported by C. L. McVey, secretary)—On the evening of February 15, 1922, the annual banquet of the association was held at the Hotel Oakland, with one hundred members present. Dr. George W. Crile was the speaker of the evening. His subject was "Special Points in Abdominal Surgery," and talk was illustrated with lantern slides.

The meeting was held on February 20, 1922, at the Public Health Center, with Dr. George Rothganger in charge of the program.

Dr. Reinle read a paper upon "Kidney Infection." He emphasized the neeessity of complete Urologieal examination in cases where urinary findings repeatedly show the presence of pus. He also brought out a new classification which described more particularly the kidney pathology with which the Urologist has to deal. The paper was discussed by Drs. A. M. Meads, E. Spence Depuy, and W. A. Clark.

Dr. Herbert Gunn of San Francisco talked on Amoebiasis. He stated that Amoebic Dysentery was a misnomer and that the disease should be called by its proper name, Amoebiasis. He discountenanced all drugs except Emetine Hydrochloride Bismuth-iodide and Neo Salvarsan. The paper was discussed by Drs. C. L. McVey and Stewart Irwin.

Dr. P. K. Gilman read a paper on the surgical treatment of Amoebiasis, emphasizing the necessity for surgery of the appendix and gall bladder, in cases which were not cured by three attempts in medical treatment. He discussed the surgical drainage of the liver. He discountenanced the use of irrigation. The paper was discussed by Dr. L. P. Adams and W. A. Clark.

Dr. Palamountain spoke of the unemployment in the East Bay district and the presence of the influenza epidemic now active, and suggested that the society take some steps towards the betterment of the condition. The matter was referred to the committee of Clinic Relations and Public Health.

Fresno County Medical Society (reported by Thomas F. Madden, secretary)—The regular meeting of the society was held at the Commercial Club on March 7, with the following present: G. W. Walker, president, Robbins, Miller, J. R. Walker, Tupper, McConnell, Tillman, Kjaerbye, Couey, Schottstaedt, Divanovich, Tobin, Willson, Hare, Schiro, Stein, Collins, Cowan, Peterson, Cross, Steinwand, Doyle, Craycroft, Pettis, Montgomery, Sheldon, Staniford, Trowbridge, Madden. The paper of the evening was read by William Fitch Cheney of San Francisco on "Diseases of the Gall Bladder." The paper gave the author's classification of the diseases and went extensively into the modern diagnostic methods. Dr. Cheney was instructing again many of his old pupils and it was indeed a great pleasure to hear him. The discussion was opened by Dr. McConnell and he was followed by Tupper, Cross, Collins and Cowan.

On Tuesday, February 21, W. E. R. Schottstaedt of the Fresno City Health Board made an address before the local Lions' Club on "Problems of the Board of Health." His subject was well handled, and gave the layman an idea of what was being done by the board.

Kern County Medical Association (reported by Wm. H. Moore, Editor and Reporter)—At the December meeting of the society the following officers were elected for 1922: President, Joseph K. Smith; vice-president, Geo. C. Sabichi; secretary and treasurer, P. J. Cuneo; censor, Edward S. Fogg; 1922 delegate, F. J. Gundry; alternate, Francis Hamlin; editor and reporter, Wm. H. Moore.

A public health committee was appointed and consisted of Drs. Hamlin, Sabichi and Moore.

Frank J. Gundry presented a paper upon "Renal and Urethral Lithiasis," which was discussed by Moore and Smith.

At the meeting of the society on February 24, at the Kern County Hospital, Keeth S. McKee was elected to membership.

Wm. H. Moore presented a paper upon "Asthma." The different theories were discussed and the reasons given why we believe asthma an anaphylactic phenomenon. The experimental artificial sensitization in animals was reviewed. In man, sensitization is inherited as a dominant factor and follows Mendelian laws. Asthmatics are of two types, sensitized and non-sensitized. The treatment for non-sensitized types is the treatment of the bronchitis and cardio-renal conditions, with possible use of autogenous vaccines.

The sensitized types are four. First—Inspired, represented by pollens, dust, and hair from animals; second—ingested, shown by the egg and milk protein sensitization in babies and food sensitization in adults; third—bacterial, represented by any chronic infectious processes giving rise to bacterial absorption as an antigen; fourth—local pathological conditions allowing absorption, as shown by the results following clearing up of chronic sinusitis, and other nasal conditions.

Authorities disagree on the relation of asthma and tuberculosis. Treatment is symptomatic during the paroxysm, and after treatment depends upon the causative factor. Certainly all possible pathological conditions allowing absorption should be removed. Then by the cutaneous reaction we determine the protein causing the anaphylactic shock. Care must be taken that patient has not been taking K. I., or the traumatic and non-specific reaction cannot be told from the true specific skin reaction.

If the causative protein is inspired, as in pollens and danders, we desensitize or render the patient refractory by repeated injeetions of diluted solutions of proteins, usually starting with 1 to 1,000,000 dilution. If ingested, we eliminate the food from the diet. Baeterial, we use vaccine of the causative bacteria. Many excellent results have been obtained with autogenous vaceines.

Imperial County Medical Society (reported by Frances P. Elliott, secretary)—The regular monthly meeting of the society was held at the Barbara Worth Hotel, El Centro, February 22, with twenty members present. A. Stanley Granger of Los Angeles gave a very interesting paper on "The Interpretation of Some of the Newer Diagnostic Methods and their Relation to Treatment." The members met at dinner preceding the business meeting.

Marin County Medical Society (reported by Chester A. DeLancey, secretary)—Due to the large number of influenza cases in Marin County, the regular meeting of the society was postponed, as all of the doctors have been kept busy night and day with these cases. There has also been a small epidemic of German measles, some of whose prodomal symptoms are similar to those of influenza.

Placer County Medical Society (reported by R. A. Peers, secretary)—A meeting was held at Auburn on the evening of March 11. Robert E. Eveleth of Roseville and Sidney Talbot of Nevada City were elected to membership. The program for the evening was as follows: "An Outbreak of Epidemic Jaundice in Nevada City, California," by A. H. Tickell, in which he reported twenty-two cases of this disease occurring in his practice during the past few months. While there may have been other cases in the State, these are the first cases to be reported in California. Richard W. Harvey, assistant professor of neurology in the University of California, gave an address on "Headaches"; and M. S. Woolf, instructor in surgery of the University of California, gave an address on "The Treatment of Varicose Ulcers." The secretary read a communication from the State Society in reference to the Indemnity Defense Fund and urged all members who had not already taken advantage of this fund to do so at once.

San Benito County Medical Society—The society met March 8, 1922, at a round-table conference with W. E. Musgrave, the State secretary, and F. H. Paterson, councilor for the fifth district. Officers for the ensuing year were elected as follows:

Lenard C. Hull, president; Richard W. O'Bannon, vice-president; Chester W. Merrill, secretary-treasurer; Emma E. McKay, delegate to the State meeting and Joseph M. O'Donnell, alternate.

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—The society met on March 7, with twenty members and five guests present and fifty-one absent. Harold Hill, M. D. of San Francisco addressed the meeting on "Recent Developments in Influenza," drawing some interesting comparisons between the epidemics of different years and describing the types of secondary infection which are likely to follow, especially the 1918 epidemic. Other papers were given by T. A. Card of Riverside on "Conduct of Second Stage of Labor," and W. Clifford McKee of Los Angeles on "The Management of the Third Stage of Labor, together with Changes in the Haemoglobin During the Puerperium." Discussion on these papers was opened by E. W. Burke.

San Francisco County Medical Society (reported by LeRoy H. Briggs, secretary)—The general meeting was held on February 14 and was devoted to Newer Methods in the Treatment of Tuberculosis, with papers by L. S. Mace on Pneumothorax in the Treatment of Pulmonary Tuberculosis; Leo Eloesser on Operative Compression of the Lungs in Pulmonary Tuberculosis, and Esther Rosencrantz on the Rollier Treatment in Tuberculosis (Heliotherapy). Dr. Rosencrantz said in part as follows:

"The Rollier method was introduced into the tuberculosis wards of the University of California service of the San Francisco Hospital and applied to both surgical and pulmonary cases.

Rollier established his first sanatorium in 1903 at Leysin, Switzerland, a mountain village 4500 feet above sea-level. Because of the purity and dryness of the atmosphere, the caloric and luminous radiation of the sun suffers very little loss. In midwinter with deep snow on the ground the temperature often reaches 95 degrees or higher.

The treatment consists in exposing the body of the patient to the rays of the sun. This exposure is gradual, beginning with the feet alone for five minutes, repeating this three times during the day. Steadily this is increased, until the entire surface of the body is exposed from early morn until sundown. It is the pigmentation resulting from exposure that is the essential element in the cure.

Rollier's method of heliotherapy was illustrated by stereoptican views showing patients before, during and after the treatment, with the restored function of the involved joints. The analysis of the 1129 cases treated in the ten years, 1903-1913, showed 951 discharged as cured and 112 as improved, 41 unimproved, and 31 deaths. In all there were only 12 relapses, and only upon ten had he operated.

The results are striking when one considers that the majority of patients had open tuberculosis with long-standing suppurative lesions, marked cachexia and amyloid disease, and were sent to him as the last hope.

There were five patients shown from the San Francisco Hospital who had received heliotherapy for many months. All were pulmonary cases; three had surgical complications as well. All showed absence of fever, marked increase in weight, the sputum negative for tubercle bacilli or absent altogether where it was positive upon entrance to the hospital. Of the surgical lesions the good results were most convincing of the efficacy of the treatment, even at sea-level. Heliotherapy is certainly a valuable adjunct in the cure of tuberculosis.

The Committee on Medicine met February 7. The program was as follows: "Bearing of Organic Disease in Childhood on Future Mental Derangement," by E. C. Fleischner; "Mental Case as Medical Case," by J. Wilson Shiels; "The Workings of the Insanity Commission and the Detention Hospital," by C. D. McGettigan. The following resolution was passed:

Resolved, That the San Francisco County Medical Society be memorialized to the following effect: That it is the sense of this, the Medical Committee of the County Medical Society, that a committee on psychopathic hospital be appointed by the president of the society; this committee to be a permanent one and to have for its object the furtherance of any measures that it may think proper toward the establishment of a psychopathic hospital in San Francisco.

On February 21 the Committee on Surgery met, with the following program: Principles Involving Fractures with Special Reference to Etiology and Treatment (illustrated by lantern slides) by Emmet Rixford.

The Committee on Eye, Ear, Nose and Throat met on February 28. This was a clinical meeting at the Eye, Ear, Nose and Throat Clinic of Stanford University Hospital. Demonstration of cases and equipment was made by the hospital staff.

San Francisco County Society—There are 1320 licensed physicians in the city of San Francisco. There are 738 members in the County Medical Society. The society wants better physicians and better medicine. The society wants every good medical man an active member. Individual effort is essential in the building of a good society. You believe in your profession, your society, and in organization for study. Will you secure one new member before the first of March? Tear off the appended application blank. Use it today. Get the applicant's signature. Have a friend endorse him. Sign it yourself. Drop it in the mail box. Do this for the good of the society. That you should bring one new member is not too much to request. San Francisco County Medical Society. LeRoy H. Briggs, secretary. Saxton Pope, president.

Sonoma County (reported by N. Juell, secretary)—A meeting was held March 16 at the office of J. H. Shaw, Santa Rosa, with twelve members present and twenty absent, and there were three guests. Dr. Tom Kelley, late co-worker of Dr. Martin Fisher of the University of Cincinnati, presented a paper on "Local Infections and Their Relation to Nephritis and Diabetes," which was very instructive and appreciated by all. Dr. Shaw gave a report of the meeting of the American College of Surgeons.

Stanislaus County Medical Society (reported by R. E. Maxwell, M. D., secretary)—The January meeting was held on the 20th in connection with a banquet in the Hotel Modesto with the following officers and members present: A. M. Field, M. D., president; J. K. Ransom, M. D., vice-president; R. E. Maxwell, secretary and treasurer; E. F. Reamer, Katherine Hurst, B. F. Surryhno, E. F. Hagedom, J. E. Hosmer, L. L. Mottram, F. R. DeLappe, E. R. McPheeters, J. L. Hennemuth, C. B. Benson and F. W. McKibbon.

Eugene S. Kilgore, M. D. of San Francisco, discussed the subject of "Treatment of Infections of the Heart." He emphasized the importance of correct diagnosis to avoid, on the one hand, the development of cardiac neuroses through overattention to functional murmurs and innocent arrhythmias, and, on the other hand, the missing of active heart infections in the frequently insidious stage of invasion. The latter cases are usually young subjects with poorly defined rheumatic infections and often without characteristic murmurs. In the quiescent stage of endo-, myo-, or pericarditis, focal infections should be eradicated and exercise adjusted (sometimes increased and sometimes diminished) to maintain éompensation and emergency reserve power. Decompensation, if possible, should be treated in its incipiency; and before the usual signs of passive congestion, teleoroentgenograms are valuable for diagnosis. Illustrative lantern slides were shown. The discussion of digitalis and quinidinc included indications, therapeutic effects and dangers. The importance of early diagnosis of syphilitic infections was pointed out. This is rendered difficult by the variety of early symptoms and the late appearance of typical physical signs. Teleoroentgenograms were shown to illustrate their aid in early discovery of disease in the aortic arch. A regime of antiluetic treatment was outlined. A meeting was held at Hotel Modesto, February 17, with the following members present: A. M. Field, J. K. Ransom, R. E. Maxwell, J. E. Hosmer, F. W. McKibbon, J. C. Robertson, F. K. DeLappe, J. W. Reed, E. F. Hagedom, C. H. Griswold, E. R. McPheeters, B. F. Surryhne, R. W. Brace, Clara Finney, J. Cooper, L. Mottram and E. F. Reamer. Max Rothschild, medical director of the California Sanatorium, addressed the society on "Modern Treatment of Tuberculosis." He said in part:

"The above title is an ambitious one and it is the intention of my address to touch only on one phase of the specific and non-specific treatment, the treatment with partial antigens and that with artificial pneumothorax. The important feature in the specific treatment is a correct diagnosis of the prevailing pathology. We have to differentiate between the exudative and the productive type of pulmonary tuberculosis; the exudative type starts in the parenchyma of the lungs and, if it progresses, leads to caseous pneumonic and afterwards to cavity formation. The other type, the productive, begins in the connective tissue and is usually followed by cirrhotic and indurating processes. Each condition appears in its pure type only in the incipiency of the disease. The more the condition progresses, the more the different types merge into each other. For the diagnosis of the correct pathological condition we have to depend upon the history of each case, upon the clinical examination and observation, upon the X-ray examinations and chiefly on the immune-biological tests. In the exudative type the treatment with old tuberculins, or toxic tuberculins, is strictly contraindicated, and in those cases the treatment with the partial antigens of Much-Deycke has given excellent results when properly used. But wherever it is possible to use the treatment with artificial pneumothorax, no matter if the case belongs to the exudative or to the productive type, this treatment is strongly advocated. The chief contraindications with artificial pneumothorax are involvement of both sides and extensive adhesions on the afflicted side."

The address was closed with demonstration of X-ray diapositives of cases treated with the partial antigens and with artificial pneumothorax.

Samuel H. Hurwitz of San Francisco spoke on: Causes and Treatment of Asthma, a consideration of the predisposing causes and some of the known etiological factors, with practical reference to protein hypersensitiveness and infection; Diagnosis of the Type of Asthma (a) The importance of history with special reference to the age of onset, the duration of the attack, the characteristics of the first attack, occupation and the exposure to the emanations of animals, to the pollen of plants, to certain proteins in the food and infection; (b) The technic and interpretation of protein skin tests; (c) The value of sputum cultures. He also discussed The Treatment of Asthma: (a) Symptomatic; the value of such agents as adrenalin, atropin, morphine, benzyol and succinate; (b) Specific treatment with proteins and vaccines.

Santa Clara County (reported by E. P. Cook, secretary)—The February meeting of the Santa Clara County Medical Society was held February 15 at the Hotel Vendome and took the form of an annual banquet. About forty members were present, spent a delightful evening of good fellowship and listened to brief addresses by John H. Graves, president of the State Medical Society, and W. E. Musgrave, secretary of the State Society.

Tehama County Medical Society (reported by F. L. Doane, secretary)—At the meeting of the society held on February 2, the following officers were elected: F. H. Bly, president; J. A. Owen Jr., vice-president; F. L. Doane, secretary-treasurer.

The Health Officer—"Health conservation is a long step from the ordinary concept of a health officer's duties—i. e., water supply, milk supply, nuisances abated and communicable diseases controlled.

"Where any attempt to meet even this outlay of duties is made a laboratory service, both bacteriological and chemical, must be available. And yet, in the first demands on a health officer, child conservation comes to the front. Most adults take boiled milk—hence milk as a health menace covers infancy and childhood.

"Gross dairy inspection means some advance over a standard of 'visible dirt,' but nothing gives a line on the real techique of milking and handling of milk in any way commensurate with bacterial studies on a milk supply.

"A pasteurizing law which does not connect up with a laboratory control of the efficiency of pasteurization is not a contribution to public health." (Adelaide Brown, M. D., in the Bulletin of the California State Board of Health.)

MISCELLANEOUS

Another Examination for Chiropractors — The Board of Medical Examiners has announced from Sacramento that special examination for chiropractors, sanipractors and other drugless practitioners will be held in Los Angeles on April 11, 1922, open to all applicants who can fulfil the requirements of the law, i. e., (1) A California high school education or its equivalent; (2) Two thousand hours professional education completed in sixty-four weeks (just one-half the education required of a medical graduate); (3) A diploma from a legally chartered school teaching the above course; (4) Certificate of good moral character.

The subjects of examination are elementary as specified in the law governing the practice of the healing art in this State.

Chiropractors, sanipractors, as well as other drugless practitioners, who can fulfil the requirements and who are inclined to comply with the law, are again offered an opportunity to co-operate with the Board of Medical Examiners in its purpose to segregate the qualified chiropractors as well as other drugless practitioners, from the unqualified now engaged in waging a campaign of misrepresentation against those who evidence an honest intent to obey the law.

Subsequent to this special meeting announced for April 11, a regular meeting of the board will be held in Native Sons' Hall, San Francisco, June 26 to 29, 1922, when examination will again be offered gratified applicants.

The Newer Medicinal Chemicals — Dr. Alfred S. Burdick, president of The Abbott Laboratories, Chicago, in a recent address emphasized the rapid growth of American chemistry through co-operation of all research agencies in this country.

Concrete examples of American achievements in synthetic chemistry were recited, and a plea made for the support of the medical and pharmaceutical professions to preclude the possibility of our again becoming dependent upon foreign sources for chemical supplies. The history of arsphenamine, barbital, cinchophen, neocinchophen, chlorazene, procaine, the benzyl esters and other synthetic medicinal chemicals was outlined. Announcement was also made of a number of new chemical bodies recently developed, and others on which research work was now being done by The Rockefeller Foundation, various universities, the American Medical Association and certain other laboratories.

In conclusion, Dr. Burdick urged both physicians and pharmacists to prescribe and dispense medicinal chemicals by the newer American names, rather than to perpetuate the pre-war dominance of foreign synthetics. This position was supported by the Council on Pharmacy and Chemistry of the American Medical Association, in whose laboratories American medicinal products have been analyzed and found to be equal and in some cases superior to foreign-made products.

Class Reunion—The class of 1912, the last class to graduate from Cooper Medical College, now Medical Department Stanford University, had a very enjoyable dinner and theater party on February 18th, to celebrate the tenth anniversary of the graduation.

At the dinner plans were formulated for a class reunion at Yosemite Valley in May, at the time of the Annual Meeting of the California State Medical Society.

Letters and telegrams were read from H. D. Barnard, Geo. C. H. Franklin, Allen D. Powers, C. E. Stagner, Geo. J. Hall, S. P. Strange, and E. J. Casper, who through illness or other unpreventable occurrences were unable to attend.

Those who attended were: H. O. Claland, W. M. Malone, F. W. Kroll, J. R. Dillon, R. H. Parkinson, J. H. McClelland, V. V. Hardeman, T. U. Sigwert, A. E. Schmidt, from San Francisco; W. A. Beattie from Sacramento, L. L. Stanley from San Quentin, R. E. Allen and Ream Leachman from Vallejo, N. T. McArthur from Napa, T. S. Long from Cambria, S. W. Dowling from Santa Cruz, and N. T. McNiel from Stockton.

California Association of Physiotherapists (reported by Hazel E. Furscott, president)—A meeting of the active members of the California Association of Physiotherapists was held March 8, and instead of the usual program plans were discussed for a constructive program which would add to the progress of physiotherapy and include all members in its execution. It was decided to take up the following problems:

1. A survey of physiotherapy schools in the United States, Canada, and Europe;
2. Compilation of a physiotherapy bibliography;
3. Survey of physiotherapy in the State of California.

The machinery to carry out this plan will be by committees which will include all active members of the association. In this way, it is hoped to obtain valuable information as well as to stimulate interest of every member by having them definitely contribute to their association.

Remedies for Certain Defects in Medical Organization and Service—(Monthly Bulletin Department of Health, New York City, December, 1921.) Lewis I. Harris, M. D., director of the Bureau of Medical Diseases of New York City, in the article in question has discussed in a most able manner a number of most important problems confronting the medical profession. Any physician interested in the welfare of his profession and interested in better medicine for all the people should by all means read this article. There are statements in the article to which most physicians will not subscribe, but these are few and are lost sight of in the broad, constructive program that Dr. Harris has outlined. Persons desiring to read this article can no doubt get it by addressing the Department of Health, New York City, and making request for a copy.

New Preparations Accepted by the Council on Pharmacy and Chemistry—During the month of February the Council accepted the following articles:

Persson Laboratories:
- Bacillus Coli Antigen (No. 50)—Persson.
- Furunculosis Vaccine Mixed (No. 37)—Persson.
- Gonococcus Antigen (No. 47)—Persson.
- Staphylococcus Aureus Antigen (No. 49)—Persson.
- Streptococcus Antigen (No. 48)—Persson.
- Pneumonia Vaccine (No. 36)—Persson.

Powers-Weightman-Rosengarten Co.:
- Novarsenobenzol—Billon.

G. H. Sherman:
- Whooping Cough Vaccine—Sherman.
- Mixed Typhoid Vaccine—Sherman.
- Acne Staphylococcus Vaccine—Sherman.
- Alypin.

Winthrop Chemical Co.:

Shall We Be Wrecked by Realism?—There is a useful lesson in this little article by Thomas L. Mossan in the World's Work for February, page 435.

BOOKS RECEIVED

American Illustrated Medical Dictionary (Dorland). A new and complete dictionary of terms used in medicine, surgery, dentistry, pharmacy, chemistry, veterinary science, nursing, biology, and kindred branches; with new and elaborate tables. Eleventh edition, revised and enlarged. Edited by W. A. Newman Dorland, M. D. Large octavo of 1229 pages with 338 illustrations, 141 in colors. Containing over 1500 new terms. Philadelphia and London: W. B. Saunders Company, 1921. Flexible leather, $7 net; thumb index, $8 net.

Solutions (in ten lessons). A manual for use in training schools for nurses. By Elsie M. Smith, R. N. Second revised edition. St. Louis: C. V. Mosby Company, 1921. Price, $1.

Epidemiology and Public Health. A text and reference book for physicians, medical students and health workers. In three volumes. By Victor C. Vaughn, M. D., LL. D. Assisted by Henry F. Vaughn, M. S., Ph. D., and George T. Palmer, M. S., Ph. D. Volume 1, Respiratory Infections. St. Louis: C. V. Mosby Company, 1922. Price, $9.

Clinical Diagnosis. A textbook of clinical microscopy and clinical chemistry for medical students, laboratory workers, and practitioners of medicine. By Charles Phillips Emerson, A. B., M. D. 156 illustrations. Fifth edition entirely rewritten and reset. Philadelphia and London: J. B. Lippincott Company, 1921.

Submucous Resection of the Nasal Septum. By W. Meddaugh Dunning, M. D., consulting otologist, Fordham Hospital, N. Y. C. New York: Surgery Publishing Company, 1921.

Lessons on Tuberculosis and Consumption for the household showing how to prevent tuberculosis, how to recognize its first symptoms, how to win back health. By Charles E. Atkinson, M. D. Illustrated. New York and London: Funk and Wagnalls Company, 1922.

Physicians' Responsibility Under the Industrial Accident Law—The Industrial Accident Commission in a recent circular letter has again called the attention of physicians to Section 53 of the Industrial Accident Law of California. The section provides that every physician or surgeon who attends an employe for injury arising out of or in the course of the employment shall make a report direct to the Commission. This report is due from every physician or surgeon who attends an injured employe, regardless of the class of employment, regardless of whether the employer carries insurance or not, regardless of the fact that the practitioner may also be in the employ of the same employer, and regardless of any and all insurance carriers. If the employer is insured, a copy of the report should be sent to the insurance carrier, as it is of equal importance that they also be notified promptly.

A QUICK AND EASY METHOD FOR THE REMOVAL OF PLASTER CASTS

The removal of heavy plaster casts is practically always a tedious task for both surgeon and patient the one wearing out his hands with the exertion of cutting and the other his nervous system with the expectation of being cut. At least this has been my observation, and is especially true when 5 to 10 per cent of cement is added to the plaster to increase its strength, as is done in the hospitals of this community.

This cement mixture makes a most satisfactory cast and one that will stand a great deal of rough handling and strain, but it is also very resistant to incision.

A given amount of plaster seems to offer about the same resistance to saws, knives, scissors and all other types of instruments, whether or not the plaster is moistened with acetic acid or any of the other substances which have been suggested as solvents. When solvents are used in sufficient amounts to be of assistance, time is consumed in waiting, and the cast is usually destroyed for further use.

These difficulties have often made me wish that my casts belonged to someone else, when it came to removing them, until I learned that the cloth is easily cut after the plaster has been powdered. This is accomplished by striking quick light blows on the cast along the desired line of incision with a small tack hammer or similar instrument, by which the consistency of the plaster is broken. When this is done, the remaining soft bandage may be easily cut with a knife or scissors.

It is better to break the line over soft tissues, when possible, than over areas where bones are prominent; however, this is not necessary, and the use of reasonable care does not bruise or abraid even in the latter areas. In many instances the area of the cast which is being struck can be completely lifted from the underlying tissues by exerting pressure on the opposite side of the cast.

Plaster does not fracture beyond the areas of impact, and, therefore, does not depress into the underlying tissues. This, however, makes it necessary to overlap the blows in order to completely break the plaster in the line.

Casts which are desired for further use are not destroyed by this method to any greater extent than when removed by simple cutting.

CLARENCE E. REES, M. D.
427 First National Bank Bldg., San Diego, Calif.

NATIONAL BOARD OF MEDICAL EXAMINERS

The dates for the next two examinations of the National Board of Medical Examiners are as follows:

Part I and II, June 19, 20, 21, 22 and 23, 1922.

Part I and II, September 25, 26, 27, 28 and 29, 1922.

Applications for the June examination should be in the Secretary's Office not later than May 15, and for the September examination not later than June 1. Application blanks and circulars of information may be had by writing to the Secretary, Dr. J. S. Rodman, 1310 Medical Arts Building, Philadelphia, Pa.

Paternalism, the Most Subtle and Sinister Enemy of Popular Government—On November 18, 1921, Congressman Frank L. Greene of Vermont delivered an address before the House of Representatives that ought to be read by every physician and every other thinking citizen of this commonwealth. Mr. Greene's subject happened to be Senate Bill 1039, but his remarks constitute a most thoughtful and sane protest against the everincreasing tide that is swinging toward paternalism and socialism in our government.

NEW MEMBERS

Charles A. James, Fresno; Paul S. Barret, Fresno; H. J. Ring, Ferndale; Caroline Rosenberg Maule, San Francisco; Wm. A. Sampson, San Francisco; Wm. H. Bingaman, Gonzales; James F. Finnegan, Vallejo; R. E. Allen, Vallejo; Frances P. Elliott, El Centro; Ora B. Dunham, Brawley; Henry B. Graeser, Holtville; Franklin H. Carter, San Diego; Thomas M. MacLachlan, San Diego; Frank J. Ratty, San Diego; Chester O. Tanner, San Diego; Arthur Wegeforth, San Diego; Manuel L. Azevedo, Sacramento; H. H. Beck, Yreka; Alverda E. Reische, Oakland; Alonzo D. Snyder, Corning; Frank E. McCann, Corning; L. E. Chapman, Gerber; Horace A. Hall, Arlington; John Jacob Kacher, Palm Springs; Wm. M. Miller, Riverside; Harry W. Smiley, Indio; Victor d'Ercole, San Francisco; W. E. Carter, Los Angeles; Thos. J. Crowley, San Francisco; L. H. Watkins, Los Angeles; Philip B. Newcomb, Los Angeles; Margaret M. York, Glendale; Joseph S. Cipes, Los Angeles; Harry J. Powers, Los Angeles; Milan J. Hart, Pasadena; Carl E. Conn, Los Angeles; Geo. B. Bormann, Los Angeles; Gavin S. Herbert, Los Angeles; Sterling N. Pierce, Los Angeles; Harvey D. Thornburg, Los Angeles; Edwin R. Butterfield, Los Angeles; Thos. McHugh, Los Angeles; Gilbert R. Owen, Los Angeles; H. N. Mayo, Los Angeles; W. B. Mayo, Los Angeles; Charles E. B. Flagg, Pasadena; Louise D. Wagner, Pasadena; Edward C. Love, Danville; Josephine E. Platt, Pasadena; Walter P. Bliss, Pasadena; De Witt C. Bryant, Los Angeles; Robert H. Kennicott, Los Angeles; Hersel E. Butka, Los Angeles; Frank W. Kidder, Los Angeles; John D. Gillis, Los Angeles; James T. Papas, Los Angeles; Ralph A. Woods, Los Angeles; Ernest I. Mulder, Los Angeles; F. H. Brandt, Los Angeles; Hugo R. Chaloupa, Los Angeles; Floyd Thurber, Los Angeles; Ben E. Grant, Los Angeles; Harry J. Schott, Los Angeles; Hubert G. Wilbur, Long Beach; C. M. Sneden, Long Beach; H. M. Griffith, Pasadena; Geo. S. Martin, Susanville; H. J. Movius, Los Angeles; Robert H. Eveleth, Roseville; Sidney Talbot, Nevada City; S. S. Goldberg, Los Angeles; Henry S. Whisman, Agnew; Donald G. Davey, San Jose; Charles L. Janne, San Jose; Ralph M. Smith, Calexico.

Transferred—Vard H. Hulen from Alameda County to San Francisco County; A. Gottlieb from San Francisco County to Los Angeles County; V. G. Alderson from San Bernardino County to Los Angeles County.

Resigned—A. W. Hitt, Los Angeles; T. R. Pratt, Los Angeles.

SOCIALIZED MEDICINE IN ENGLAND

The public press of England is furnishing some illuminating information about the workings of their so-called health insurance laws and particularly as to the sorry plight of both the public and profession in a country where State medicine of the government variety is so generally in force. We read that the Medical Practitioners' Union, after passing a resolution fixing an irreducible minimum fee at 13s. 6d., were forced by arbitration to accept 11s. as a "minimum wage." It seems that the government is about to try to force a still further reduction on the ground that other union wages are being reduced. The public, of course, is objecting to the amount of the capitation tax, and everyone is just about as unhappy as they might be expected to be under the state administration of a great personal service profession. Not so long ago, the profession of England gave to the world constantly of its progress in the medical sciences. Fakers of various sorts and walking delegates seem to have most of the limelight now. Perhaps the most significant phase of the discussion is the general and drastic criticism of the powerful and expensive machine that has been built up for the administration of their intricate political law for the care of the sick. We are told that there is another side to the picture, but we are also told that this other side is sponsored only by those who are interested parts of the machine.

Shriners' Hospital for Crippled Children—The Board of Supervisors of the City and County of San Francisco on January 9 finally passed a resolution authorizing the Board of Trustees of the Shriners' hospital to maintain and operate a hospital for crippled children in the block bounded by Nineteenth and Twentieth avenues, Lawton and Moraga streets.

Napa State Hospital—The State Hospital at Napa is shortly to have repairs and extensions involving the expenditure of about $85,000 most of which is for a new home for employes.

DEATHS

Wilcox, Glover B. Died in San Francisco, March 13, 1922. Was a graduate of the College of Physicians and Surgeons, Los Angeles, Calif., 1908. Licensed, 1911. Was a member of the Medical Society, State of California.

Corpé, S. L. Was killed in El Monte, Calif., when the car he was driving stalled on railroad track. Was a graduate of Hahnemann Medical College, Ill., 1894. Licensed in California, 1911.

Shepard, Gilbert. Died in Santa Cruz, Calif., March 7, 1922. Was a graduate of Hahnemann Medical College, Chicago, Ill., 1870. Licensed in California, 1896.

Peebles, J. M. Died in Los Angeles, February 16, 1922. Was a graduate of Philadelphia Medical and Surgical, 1876. Licensed in California, 1894.

Dale, H. M. Died in Los Angeles, February 27, 1922. Was a graduate of the Medical Department, University of Iowa, 1894. Licensed in California, 1901. Was a member of the Medical Society, State of California.

Rowell, George Ball. Died in San Bernardino, January 11, 1922. Was a graduate of McGill University, 1886. Licensed in California, 1888. Was 62 years of age and born in Canada.

Welch, Henry Seely. Died recently in San Francisco. Was formerly a surgeon in Second Regiment of Infantry, National Guard. Age 73. A graduate of Bellevue Hospital, Medical College of New York City, 1872. Licensed in California, 1876.

Macauley, Henry A. Died in Midway Island, November 28, 1921. Was a graduate of the University of New York, 1887. Licensed in California, 1910.

Toland, Marcellus R. Died in Los Angeles, February 5, 1922. Was a graduate of Southern Medical College, Atlanta, Georgia, 1883. Licensed in California, 1887.

Etcheverry, M. H. Died in San Francisco, March 1, 1922. Age 43. Was a graduate of the College of Physicians & Surgeons, San Francisco, 1902. Was a member of the Medical Society, State of California.

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.

A STATEMENT OF THE PROBLEMS OF INDUSTRIAL MEDICINE IN CALIFORNIA

By GEORGE W. GOODALE, M. D., San Francisco

There are two distinct factors in industrial medicine which threaten the welfare of the medical profession and the efficiency of this service to the public:

First—The existing dissatisfaction of the medical profession with the present status of industrial medical practice, with the possibility of internal strife arising disastrous to our State organization.

Second—The existing economic warfare of insuring companies threatening the almost inevitable sacrifice of the medical profession on the altar of business economy.

The existing dissatisfaction of the medical profession regarding the present status of industrial medicine is due to various causes:

(a) The average physician cannot understand why he cannot treat a patient who is one of his clientele for industrial injuries, and he cannot understand why the ordinary rules of professional etiquette for private practice do not apply to industrial cases. Consequently, he is subject to all the irritation that occurs when one thinks that one's personal rights are being trampled upon unjustifiably. A great deal of this condition exists on account of the ignorance of the average physician regarding the details of the Compensation Law. He has little, if any, knowledge of what constitutes, under the Compensation Law, the rights of the physicians, the patient, the employer and the insurance companies, and, consequently, has no proper standard to guide his own actions.

(b) A great deal of dissatisfaction in the medical profession arises from the experience of physicians who only occasionally handle industrial cases, both at the amount of remuneration received and the treatment accorded them by insurance companies.

They feel that as physicians they must render emergency aid whenever or wherever asked, and feel keenly the injustice of being paid a paltry sum for work that was unsolicited and undesired, and only performed because their duty as a physician required them to act. This condition is largely due to an impractical fee schedule which takes no cognizance of varying classes of physicians or of varying degrees of service.

The dissatisfaction with the treatment received is largely due to the lack of knowledge upon the part of the physicians of what is required by insurance companies in carrying out the detailed administration of the law. The insistence that the physician follow certain set rules of procedure and reporting is often the foundation for misunderstanding between the physician and the insurance company.

(c) The next cause of dissatisfaction is limited to a relatively small portion of the profession. The cause of this is the inability of many surgeons, who desire industrial work, to obtain it. These physicians would like to be put upon the special panels of the companies, and, failing in this, would like to have panels abolished altogether.

In the eight years since the inception of the Compensation Law, the medical work of the companies has settled into definite channels, and physicians seeking this work find it very difficult to change it. The complaints arising from this condition, while undoubtedly from the smallest number, are also undoubtedly the loudest and most persistent.

Let us next consider the economic warfare of insuring companies and in what manner this threatens the welfare of the medical profession. In analyzing any problem, whether it be business, political or medical, and this problem embraces all three, motives and trends are more important than individual statistics.

In the beginning, the importance of the Compensation Law to the medical profession was hardly thought of and certainly not appreciated. At that time the persons vitally interested were employers, employes and lawyers. The enactment of the law was largely the result of revolt fostered by labor unions, and sustained by public opinion, against the old liability law and the very serious wrongs that were inflicted upon injured employes by employers and insurance companies. The motive of these wrongs was an economic one.

The law provided certain penalties against employers, which the employer met by transferring his obligations to an insurance company. The insuring company which survived was one able to quote the lowest rates for insurance. The one

who could administer his business the cheapest could give the lowest rates, and, consequently, got the business. Successful companies retained lawyers on a salary, made collection by plaintiffs as difficult as possible, and paid few claims. This competition crushed the employe, as he was the weakest and least able to protect his rights. The trend at that time was strictly against the laboring man. The motive of the Compensation Law was to save the laboring man and, by numerous safeguards provided in the law, this was accomplished.

The establishment of the Compensation Law was received with varying emotions. The lawyers were disgusted at being deprived of a certain amount of their business. The doctors were divided, some looking upon industrial practice with disfavor, and others ready to give it a fair trial. The insurance companies were disgruntled over the loss of their liability business. However, the attitude of the insurance companies quickly changed as they realized that the field of compensation insurance was much larger than that of liability insurance, and while the percentage of returns was much smaller, the volume more than compensated for its loss.

Shortly after the initiation of the law there was a period chiefly marked by a wild scramble for business. Little attention was paid to service, and most to rates. Irresponsible companies proceeded to cut rates without any thought to ultimate results, and the consequences were that as soon as returns began to come in, losses began to show. One company in particular failed with a great loss to injured employes, and other companies were forced to quit writing compensation insurance. The fight at that time was between what were known as board and non-board companies. The board companies, with few exceptions, held to full rates; the non-board companies wrote at cut rates. To meet this condition of affairs, there was a law passed, called the Minimum Rate Bill, and a board was appointed from insuring companies and State Fund under the direction of the Insurance Commissioner to adjudicate rates and no company was allowed to cut these rates. This, to a large extent, stopped rate cutting. What cutting was done, was done surreptitiously. Not being able to gain business by rate cutting, the companies were forced to appeal for business on the grounds of giving better service.

Now comes the development of another step. The State Compensation Insurance Fund was primarily established to hold in check stock companies so that they would not be able to combine and put through, by concerted action, policies that would be injurious to the best operation of the State Compensation Law. The original intent of the law was not that the State Fund should be a competitor of the companies in the sense of a business competitor, endeavoring to obtain all business possible, but a competitor whose presence in the field would make impossible any injurious practices by stock companies. However, as time progressed, this attitude of the State Fund changed. The common fault of bureaucracy quickly manifested itself. Bureaus, like individuals and corporations, desire to grow and to aggrandize other fields. The State Fund was not content with simply being a check on the companies and became an active competitor.

Insurance companies are allowed by law to pay a certain percentage to brokers for obtaining business for them. The State Fund, not being considered in the beginning as being created as an active competitor, was forbidden to pay any brokerage fees. This, in certain conditions, would be harmful in business getting, but under certain other conditions it works out quite the reverse. Not having to pay brokerage fees, and not having to pay stockholders' dividends, in an economic race the State Fund had a marked advantage. While the law prohibited the State Fund from paying brokerage fees, it did not prohibit the manager of the State Fund from hiring special agents who supplanted the broker in his special province of contact man with the employers. The salary of special agents, needless to say, was much less than commissions to brokers.

Given a large company, turning back large rebates on premiums, it was inevitable that the company able to do this would get a large proportion of the business, and this is exactly what happened to the State Fund. Not being able to meet these conditions brought about the last shift in insurance conditions. Stock companies forced the adoption of what is known as the "Experience Rating Plan." Instead of a minimum rate, any plant whose experience showed that it had operated at certain compensation costs below the minimum rate was allowed a rate based upon its own experience. This, if carried out correctly, would do away with the advantage of the State Fund, and the companies would be able to quote them a rate that would be as attractive in a business sense as the State Fund could give. The whole proposition amounted to each assured's insurance rate being based upon its own experience rather than upon general experience, which is the common rule in determining insurance rates. This puts the cost directly to the owner, the consequence being at the present time that the company which can operate the most economically stands the best chance to get the business.

There are four factors of importance contributing to the expense of admistration of compensation insurance — administration expense, compensation losses, safety engineering, and medical service. Of all these, the medical is the most valuable and the most important.

While, at the beginning of the compensation era, a great deal was said about economics and cheapening of the medical, the real motive which determined the centralization of medical was the need of having the medical business handled in a systematic way. To clear their tables, adjusters were compelled to have physicians who would co-operate.

Another period now arose coincidental with the Minimum Rate Law. This stabilized the business of the stock companies, and their motive then was that of better service. This was reflected in

the medical service, and the physicians or organizations who could give the best service to a large extent dominated the field. This marked the greatest advance in medical service. To obtain the business, it became necessary to give the best of everything: Offices, emergency service, specialists, rehabilitation treatments, X-ray and laboratory work, with the best of clerical and administrative service. This period extended through the boom periods of the war and until the last few months when, with the conflict between the State Fund and the stock companies for business, this has brought about another change. Rebating by the State Fund as a business propaganda, and the Merit Rating System of the stock companies, bids fair to bring about an economic warfare during which the opposing sides will attempt to exploit the services of industrial physicians and surgeons.

To summarize, insurance is now being sold at cost, and whoever reduces the costs gets the business. Administrative expenses are practically stationary and afford little opportunity for saving. Installing of safety apparatus is limited in its field, although it has some bearing. In compensation payments, the injured employe is so protected by the Industrial Accident Commission that little, if any, saving can be made there. The most variable cost, and the place where the most can be done, is the medical, and that is where the axe is bound to fall.

Under the old liability law, the saving was made off the injured employe, and on account of his weakness he was ground between the millstone of economic competition. At the present time it looks as if the medical profession bade fair to take the place of the injured employe in being the grist of the business mill unless in some way it can protect itself. Companies, not necessarily because they desire to, but because they are forced to by competition, will get their medical service as cheaply as possible. Such is the condition that confronts us from the companies' standpoint; on the other hand arises another complication to further embarrass us:

In the beginning of the Compensation Law most physicians took the attitude of sneering at the work and either refusing to do the work or did not endeavor to conform to the necessary requirements, of proper reports. Now a revulsion of feeling has come upon the medical profession.

With the passing of boom times, the medical profession feels the pinch the same as all other lines. Consequently, a great many of them are now very anxious to obtain the work which they at first despised. While at first they had an exaggerated idea of the smallness of the fee, now they have magnified the amounts received by industrial surgeons and are very desirous of participating in this imaginary wealth. The fact that many surgeons are now desirous of obtaining the work makes competition much keener. The economic warfare of the companies under the merit system of rating, and the competition among surgeons for the business, is going to mean, unless wise and constructive measures are taken, very cheap medical service.

Before attempting to prepare any plan, it is well that we take stock of ourselves. The problem before us is one of economic warfare, and might is superior to right when right is unorganized and unable to defend itself. In this field we cannot command respect unless we have the ability to enforce the same. We must admit that as far as looking out after our own interests is concerned, in the administration of the Compensation Law, the medical profession has not been a success.

The cause of our failure lies, first, in the belated recognition of the importance of the Compensation Law to the medical profession. Second, in the establishment of a special fee schedule, open to all with no conditions attached. Third, in the failure to recognize the fact that we are not dealing with patients, but with centralized medical corporations whose patients number all the workmen in the United States and whose field of action is the whole country. Fourth, a lack of centralized authority, with power to act, to represent the interests of the medical profession in the industrial world. Fifth, the lack of a practical plan by means of which such centralized authority can reward or punish recalcitrant companies and members of the profession.

As to the first cause of failure: Fortunately, the profession have at last been aroused to the importance of the Compensation Act and similar laws. I think that they are now willing to give this subject the consideration it deserves and that the best minds, who have the interest of the profession at heart, are prepared to take any action necessary for our preservation. Without this, it would be impossible to accomplish anything, but with full co-operation we should be able to work out a plan that is both feasible and effective.

The second cause of failure was the adoption of an unconditional fee rate schedule. Having given a schedule open to all companies alike, the Medical Society left itself no means of dealing with individual companies. Fortunately, the original schedule has been raised, leaving us a margin that can be used in drawing up a preferential fee schedule, if we so desire.

Third—Industrial medicine deals, economically, not with patients but with corporations. Rules governing physicians in their relations with private patients are not applicable to physicians in their relations with corporations. Complexities in social organization have so arisen that Hippocrates would be forced to rewrite his celebrated epistle if he wished to cover all points necessary for the guidance of our actions. As the United States has today been forced to a new foreign policy, so today the medical profession is forced to add on additional features if it wishes to protect itself and those it serves.

Fourth—Lack of centralized control. Today the State Medical Society is largely governed as a democracy. True, it has a State organization and a State council, but their authority is extremely limited. The ultimate authority of the Society

rests in county units. While this system has proven itself to be very efficient in the past, it breaks down when confronted with the necessity of dealing with centralized organizations that are not only State but National in their scope of action. Only a centralized authority invested with power can defend itself in controversy with insurance corporations. This centralization of power should eventually be National as well as State. Since the present machinery of our Society does not permit such a centralization, it becomes necessary for us to evolve a plan of government that will meet our needs.

Fifth—At the present time we lack a plan of action to meet special needs in the industrial world.

The needs of the present situation require the evolvement of a plan which shall allay dissatisfaction on the part of the general profession, provide a competitive field in industrial medicine open to all physicians of our Society, and protect the profession from being sacrificed in an economic warfare. Evolvement of such a plan is, indeed, very difficult. Many varying factors must be taken into consideration; it must be so safeguarded that in helping one we do not injure another, and at the same time the broad policy of acting in a practical way for the good of the whole profession, and not of the individual, must be followed.

When we deal with individuals, whether companies or doctors, concrete facts and not general theories are what count. Without the support of a majority of the insurance companies, it is futile to plan; without almost united support of the medical profession, any plan is bound to be a failure.

THE POPULARIZATION OF MEDICAL KNOWLEDGE

By HENRY I. LEVITON, M. D., Los Angeles

In one of last year's issues of the *Journal of the American Medical Association* there appeared a practical editorial commenting on a thesis by the French physician Georges Bourgeau.

Bourgeau takes for his subject "The Relation of the Public Press to Medical Science." He divides his monograph into two headings. The first deals with the laxity of the French law bearing on the quack and the patent medicine manufacturers. The second deals wtih the unintelligent and unscientific, often distorted, presentation of medical facts in the public press.

My intention is to add to Bourgeau's thesis an appeal for a closer relation between the laity and the medical profession in an attempt to popularize medical knowledge.

In California physicians are confronted with lax and harmful public health laws; are sometimes attacked and insulted in the public press, and they are even accused of preying upon the sick and the dying. Most physicians go about their work without paying any attention to these attacks. In a way, this is the proper manner to act. Silence is golden. But let us not forget that silence is falsely interpreted as an admission of guilt.

Every physician knows that these attacks are wilful propaganda, often based upon ignorance and superstition. Some of it, no doubt, is due to misunderstanding. It is our duty to the public and to ourselves to bridge the chasm incident to this misunderstanding by a bridge of common sense in the form of intelligent dissemination among the people of medical truth by means of the public press.

The day of serecy, the day of the mysterious in medicine, is as much a thing of the past as the proverbial doctor's stovepipe and whiskers. They belong to the rubbish heap. Affectation in dress and personal appearance, the particular mannerisms and the air of the mysterious that characterized the doctor of yesterday, was probably an asset with our grandfathers. With us it is a liability. It savors of the charlatan. Modern medicine is above board. So must modern doctors be. *The science of medicine is our greatest asset. This science we must endeavor to make accessible to the people; thereby increasing the safeguards to the health of the public and destroying the influence of charlatans.* Medicine is daily becoming a science more definite, more concrete. Therefore its honest and frank exposition is a duty we owe to the public as well as to ourselves. Indeed, medical Evangelism is becoming a national necessity. Medical missionaries are needed right here in our United States as much as, perhaps even more than, in China or Turkey. There is here in our land a movement daily growing more vicious in its attacks upon scientific medicine and national health laws. This evil was pointed out in a recent editorial by the CALIFORNIA STATE JOURNAL OF MEDICINE, which says in part: "Various mental healing methods based upon religion and pseudo psychology are on the increase." This is particularly true of some of the so-called scientific branches of the cultists. Much of this sort of "psychology" literature is thoroughly saturated with propaganda of a vicious type, dealing particularly with dreams and sex. After acquiring a flimsy educational veneer their professors begin to style themselves "psychologists" and "mental efficiency experts," and what not. And a constantly increasing number of them are selling a pseudo medical service to the public under one form or another. In fact, a new species of this sort of spellbinder appears with every issue of the Sunday papers, advertising wondrous magic cures by electricity, massage, water and air, both hot and cold—especially hot.

As every scientifically informed man knows, in the "colleges," in the offices of these spellbinders, in fact, even in the courts and on the floor of our State Capitol, they attack the program of scientific medicine as well as its standard of practice. Indeed, they assault the very citadel of science itself. They attack it with all the blind fury the dark ages attacked Bruno and Galileo.

Nor must it be thought that since science is true it needs no other defenses than its own truth. Truth will endure only so long as it has defenders whose arms are strong. Otherwise it may be trampled in the mire as much as the most vicious lie—even more. The history of the past is shock-

ingly fraught with experiences where truth was most barbarously, most cruelly trampled in the dust, while falsehood was enthroned on a pedestal of gold. And, therefore, there is not the slightest doubt that if these magic healers succeed, all the other learned professions—engineering, agriculture, architecture, etc.—will come next. This question thus deserves the critical attention of every man, not as a matter of protecting a particular group who happen to be indispensable to the welfare of the nation and the race; but as a matter of preserving the most ancient and most noble of all the sciences. The quacks are overrunning the country with their most absurdly senseless health doctrines; and we, the educated guardians of the health and life of the nation, ostrich-like hide our heads in our scientific medical journals, allowing the truth about these vital subjects to remain unaccessible to the public.

The scientific facts of recent medical discoveries are daily being distorted and misrepresented by a certain type of public press—to the detriment of the public. One need not be a physician to be stirred to indignation.

Of all people physicians should be the first to insist that all medical truths be made known to the public. If possible, we ought to see that this is done by means of the public press. This agency should serve as the medium through which medical men may impart to the people the true facts of the latest medical discoveries.

In his monograph Bourgeau mentions that even such authoritative newspapers as the Paris Matin handle very carelessly, often even distort almost wilfully, matters pertaining to scientific medicine. Thus what may be termed dangerous handling of some of the most important medical subjects may result in failure on the part of the ailing to seek competent medical advice in time. This in turn results in hopeless protraction of such diseases as syphilis, tuberculosis, and cancer. The patient first tries all the "cures" advertised by the newspaper. When he finally comes to the physician he is in a hopeless condition. Bourgeau cites as an illustration some of the headlines of the Paris Matin on this subject, some of which I beg to reproduce here and request the reader to look for similar ones in his own paper:

"Contagion Has Been Abolished in Scarlet Fever"; "The Transfusion of Blood Is a Dangerous Procedure to Donor"; "Anteriosclerosis Vanquished"; "One-Half of Those Who Are Deaf Are Cured by Radium," etc.

All of us remember the sensationalism of the so-called interstitial gland transplantation. The evils of such medical falsehoods are self-evident to the physician.

The only remedy is the popularization of medicine. It should be expounded by medically trained journalists. This will result in a closer understanding between the laity and the medical profession, and will remove the ancient veil of mystery and secrecy. In the comment referred to above, the *Journal of the A. M. A.* states:

"Bourgeau's criticism of the French press applies with equal weight to the press of the United States. Fortunately, in this country there is at least a beginning of betterment, for a few of the larger and better class papers have recognized the necessity of greater accuracy of this class of reporting and have a trained personnel to cover matters of this sort and insure that the written account may be something more than a fanciful story written by one to whom even the terminology of the subject is an unintelligent jargon."

But to bring about a condition where matters would be at least tolerable physicians must see to it that some of our journalists are trained in the science of medicine and some medical men acquire the art of journalism. This is the only hope we have in popularizing the knowledge of medicine and ridding the world of the pestilential influence of the "healers" who prey upon it in a thousand ways.

(1115 Story Building, Los Angeles.)

POPULAR HEALTH ARTICLES

The League for the Conservation of Public Health is editing and conducting a department for the San Francisco Examiner and the Los Angeles Examiner devoted to popular health articles written by scientific medical men. The combined circulation of these two papers daily is a quarter-million and the Sunday editions are read by more than a half-million people.

The League has requested us to invite all the members of the State Society to send to the Executive Secretary of the League, Butler Building, San Francisco, timely articles, of about 500 words each, expressing in popular terms some concrete facts or phase of scientific medicine. All the various scientific agencies and methods that are used by scientific medical men to promote and protect health, to combat and cure disease, come within the scope of the articles which are being published in the Better Health Service conducted by the League. As a practical method for popularizing medical knowledge this enterprise of the League merits our fullest co-operation.—[Editor's Note]

TREATMENT OF OAK DERMATITIS CAUSED BY RHUS DIVERSILOBA

By HARRY E. ALDERSON, M. D., San Francisco

Since the articles published by Schamberg,[1] Strickler[2] and Alderson,[3] describing the specific treatment of poison ivy and poison oak dermatitis, there have been many inquiries regarding the use of this substance. As most correspondents ask practically the same questions, this article will serve to answer all of them.

The preparation is not a "serum." It is an alcoholic solution of the toxin of the poison oak plant (rhus diversiloba). It is prepared as follows: A given weight of fresh crushed leaves of rhus diversiloba is covered with absolute alcohol, extracted, filtered and precipitated, and the precipitate dried at low temperature. A given weight of the toxin is dissolved in absolute alcohol and sterile water added. An arbitrary standard is set for the weight of the toxin, volume of absolute alcohol and the volume of sterile water. It is hoped to be able to standardize the preparation soon.

A large quantity was made in this way by George Broemmel, B. S., Ph. G., Ph. C., and its toxicity tested on various laboratory animals. It was found that as much as 3 cc. had no toxic effects aside from the alcohol action on guinea pigs.

It is not a "secret proprietary article," but can

be made by any competent chemist who has access to a supply of fresh poison oak (rhus diversiloba) leaves and twigs. It is advisable, however, to try out the newlymade toxin on the guinea pig to determine its toxicity before using any given lot.

We have had no untoward effects. Out of several hundred patients injected only a few have felt faint or nauseated, and in each instance this was due principally to psychological factors. One patient developed hyperesthesia and various other purely nervous symptoms which were due to other causes.

Our greatest success with this substance has been in the treatment of cases of acute dermatitis venenata due to poison oak, but we feel that in many, greatly increased tolerance for the poison has been produced, so that the patients appear to have become immune. As this is not like the immunity produced by bacterial products, it is felt that one should take a course of the toxin every year. This is because tolerance for any chemical poison which is acquired by taking the same in increasing doses gradually wears off (as, for instance, with arsenic, nicotine, morphine, etc.). However, some poison oak patients seem to maintain their tolerance for longer periods than others. This latter observation has been made of those who seem to have "natural immunity." Occasionally those possessing this "natural immunity" lose the same and they at times may show great susceptibility to the effects of the plant. So far no satisfactory explanation of this phenomenon has been found.

It is not claimed that this treatment is invariably successful. We consider, however, that in most cases the results by this method are superior to those that we have seen after any other plan of therapy. The acute symptoms almost invariably subside promptly. Repair of the damaged skin naturally is slower with some individuals than with others. This terminal dry, peeling phase may last several days, but should not be regarded as being part of the *active* poison oak dermatitis.

Method of treatment in active cases.—With very young children we have not attempted to give the injections, but have administered the more dilute solution by mouth, regulating the dosage according to the usual rules applying to therapy in pediatrics. We have given 0.5 cc. of the toxin intragluteally to children over six years of age with good effect. With older patients from 0.5 to 1.5 cc. are given *intragluteally* and the dose is repeated again in twenty-four hours, and again twenty-four hours later if improvement in the subjective and objective symptoms is not very definite. Usually within forty-eight hours there is great improvement and it is seldom that a third injection is found necessary.

At the same time the following solution is given by mouth until finished:

Rx:

Oak toxin solution	4	0
Aromatic elixir q. s. ad.	90	0

M. Sig.—Begin with gtt. X in water t. i. d. p. c., increasing by one drop each dose until gtt. XX are being taken. Then take one teaspoonful once daily.

By this method tolerance for the poison may be established. It is recommended that this solution be taken in the manner prescribed once a year. It is hardly necessary to warn against getting the solution into a vein; also it should not be given unless one is sure that the dermatitis is due to poison oak and not to the primrose or other plants, hair dye or other chemical irritants.

AN OUTBREAK OF EPIDEMIC JAUNDICE IN NEVADA CITY, CALIFORNIA

By A. H. TICKELL, M. D., Nevada City, Calif.

During the early part of November of last year there occurred in my practice two cases of what then appeared to be catarrhal jaundice. Following these, however, some twenty other cases have arisen, so that it became forcibly impressed on me that an infectious disease was prevailing.

In the Journal of the A. M. A. of January 14, 1922, appears an item regarding suspected epidemic jaundice in New York State, due to groups of suspicious cases in Madison, Oswego, and St. Lawrence Counties. The outcome of the investigation I have not as yet learned.

Dr. Herman of New York City also reports in the Journal of January 28, 1922, that a large number of cases have occurred in that city during the past three months. These reports coincide very closely with conditions existing here.

The infection still persists and new cases are appearing. Age apparently is not a factor as I have had patients as young as five and as old as forty years, the young, however, due to their greater exposure to contact in school and homes, being in the greater number. In homes where two or more children reside, the disease shows a definite tendency to spread from one to the other; the period of exposure to outbreak being about two weeks.

The disease is characterized by sudden onset, abdominal pain, and fever accompanied by chills. The fever continues according to the severity of the cases, which vary greatly. Muscular pains, headache, nasal hemorrhage, severe nausea, enlargement of the liver and spleen, followed often by pronounced general weakness are also usual symptoms. Jaundice appears about the third or fourth day after the onset, with clay-colored stools and bile-stained urine, at times containing blood.

In the Reference Handbook of the Medical Sciences, under the synonym of "Weils Disease," a quite complete history of this disease will be found. The writer, however, describes the conditions as existing in Europe and Japan, stating its occurrence is rare in this country. We must take into consideration the improved living conditions and general hygiene which go far to mitigate the virulence of all infectious diseases, and not be misled when confronted by milder conditions that simulate classical descriptions.

The origin of the infection in this section is obscure, but in all probability it has been brought in by food and spread by rats and mice, as a large proportion of the vegetables and fruits are sent in from the truck farms of the valleys, where foreign and Japanese labor is largely employed.

Treatment has been largely symptomatic, with rest in bed. The initial nausea and tenderness appeared to be controlled by constant hot, moist applications over the region of the gall-bladder. Prognosis has so far been favorable. Prophylactic measures should be taken and all excreta attended to, as in typhoid.

EDITORIALS

THE FIFTY-FIRST ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

This issue constitutes the official convention number of the Journal. It contains the complete program and a very considerable amount of information regarding transportation, hotel accommodations, methods of procedure and other facts that members and visitors will want to know.

Every effort has been made to have the program as complete as it is possible to make a program covering so many subjects. An attempt has been made to arrange the different section meetings so that specialties covering allied fields hold their meetings at different hours. It has not been possible to arrange this to the complete satisfaction of the committee, and constructive criticism from various members and section officers of improvements for the next State meeting will be welcomed. The General Sessions have been so arranged that all members and visitors at the convention may attend without losing opportunity to keep in touch with sections that they are interested in.

Every member and all guests at the convention are requested to submit to the secretary suggestions that will tend to make next year's program better than the one of 1922.

It is particularly requested that all members, guests and visitors register as soon as they arrive in Yosemite. An outline map has been made of the valley, showing the location of headquarters, hotels, convention halls, roads, and the times and places of all meetings. These maps will be at the registration desk and at each of the three information offices.

INFORMATION ABOUT ROADS TO YOSEMITE

An Official Statement by W. H. Lewis, Superintendent of the Park

A week of clear, sunshiny days has nearly erased all evidence of winter on the floor of Yosemite Valley, and the cottonwoods, the first of the larger deciduous trees to bud, are showing a tinge of green. The bright, warm days have also had their effect on the snows of the high altitudes, whose rapid melting is filling the watercourses and the great waterfalls are booming again after months of little activity. However, the warm weather has been late in coming and the snow in the back country lies deeper and more solidly packed than in many years. The effect will be to retard the opening of motor roads into the park, but this will be in a measure compensated by the lengthening of the water season.

Yosemite goes into this season of "The Open Road" better equipped than ever to care for its tens of thousands of visitors. Additional housing and feeding accommodations will be made available by the park operators, as well as added transportation facilities, both for rail and road travel.

CHIROPRACTIC AND OSTEOPATHIC INITIATIVES

Two surviving members of the "Quack Quartet" will appear on the ballot handed to each voter at the general election November 7. In numerical order they appear as Number 16—the Chiropractic Initiative, and Number 20—the Osteopathic Initiative. If these "Spinalese Twins" were the only measures which the voters had to consider they would be defeated by an overwhelming majority. The people of California have gone on record innumerable times against anti-health legislation. Again and again the people have expressed emphatic approval of maintaining definite legal, educational and moral requirements for those licensed to treat the sick.

But these two pernicious proposals are placed upon a ballot that will contain fourteen constitutional amendments, bond issues, referendums and other initiatives, some involving questions of very vital importance to the welfare of the State. In addition to these, the voters are confronted with selecting from long lists of candidates the ones best qualified to make, interpret and enforce the laws of the State.

Few voters can spare the time to investigate the extravagant claims made by this aggressive Chiro-osteo combination. If those who are informed neglect to co-operate in broadcasting the facts and exposing the vicious character of these two initiatives, it is probable that quackery will win and create a chaotic condition in the field of medical, hospital and health work. But quackery will be more decisively defeated than in previous campaigns if those who should be interested will co-operate with the League for the Conservation of Public Health in this 1922 campaign.

These two initiatives would *establish Cult Boards* devoted to absurd theories that practically repudiate the successful experience of scientific men and reject the demonstrated facts of modern medicine. They are a *public* challenge to our universities and educational institutions, to the organization and administration of all our health departments. If the Chiro-osteo combination is correct, all the appropriations for medical education, all the wealth and work being spent to combat and conquer disease, should be abandoned as wicked waste of money and effort. Tuberculosis, scarlet fever, diphtheria, infantile paralysis, measles, bubonic plague, smallpox, typhoid fever and other reportable diseases cannot be accurately reported or safely treated by Cultists who advertise that "epidemics are produced to make dollars for Doctors," and who maintain that the cause of all disease is invariably subluxated vertebrae, and the method to cure all disease is to adjust said subluxated vertebrae. The value of vital statistics, the virtue of quarantine laws, the efficacy of all preventive measures would be vitiated by practitioners of such unsafe and unscientific theories.

All health departments, State, County and City, all hospitals interested in maintaining scientific standards, all civic and fraternal organizations,

women's clubs, insurance companies and welfare societies that are engaged in various forms of health work, should actively oppose Number 16—the Chiropractic Initiative, and Number 20—the Osteopathic Initiative. If all these agencies are actively interested in defeating Nos. 16 and 20, we can assure them the effective co-operation of the League and every ethical member of the medical profession. A triumph for quackery will not mean a defeat of the medical profession, but it will mean that hospitals, universities, laboratories, health departments and all valuable health agencies will be jeopardized, because you cannot impede the practice and progress of modern medicine without, at the same time, undermining the various agencies and fundamental sciences that the medical profession employs in its worthy work.

SALARIES VERSUS FEES

The office of the State Society is receiving a very considerable number of inquiries as to whether or not it is ethical for a physician to work for a salary or whether all work should be strictly upon a fee basis. The editor is not prepared to answer this question until the Council or the House of Delegates have expressed themselves.

It is interesting, however, to look at a few facts and estimates: It is probable that more than 30 per cent of the licensed physicians of the United States are men who are receiving salary compensation of one sort or another. It is probable that a slightly smaller percentage of the members of the California State Society are also receiving salary compensation. Salaries are paid for full-time work, part-time work, or more or less indirectly as piece work or "for service" compensation. It is, of course, a fact that medical departments of the Army, Navy, U. S. Public Health Service and the medical department of every one of our Federal Bureaus of every description are operated by full-time salaried physicians. Teachers in medical schools and universities receive part-time or full-time salaries. It is also a fact that the vast majority of state and county, city and municipal health officers are paid what amounts to salary compensation, usually for part-time service. A large number of insurance companies of various kinds have medical departments of salaried men, either salaried in full or for part time. Most of the insurance companies have their medical advisory boards in their home offices upon a salary basis for part-time work. The majority of large industrial and commercial organizations—railroads, telegraph companies, industrial plants, lumber companies, mines and similar organizations—have their own salaried personnel constituting their medical departments.

This phase of medical and public health development on a salary basis is increasing everywhere. Transportation lines, railroad companies, and steamship lines employ thousands of physicians on full-time salaries. Many physicians themselves and large numbers of hospitals engage a certain percentage of their assistants on full-time or part-time salaries. Publications, including newspapers and magazines, employ salaried medical departments. News service bureaus and organizations of one sort or another employ a considerable number of physicians on full-time salaries. Hospital associations, group organizations operated by physicians and by laymen, and similar activities are employing constantly increasing numbers of physicians on salary, and so on through dozens of other activities.

With these facts before us, is it not purely an academic question as to whether or not it is ethical for a physician to work for salary compensation instead of a fee schedule?

MAKING A MOCKERY OF THE LAW

There are about 7000 persons who have passed the legal tests and are authorized by law to practice the healing art in the State of California. There are others who are practicing illegally. Not only is the law passively disregarded in this respect, but the majority of these law violators are open and aggressive in their denunciation of the law and in their disrespect for its provisions. Magazines, newspapers and other circulating media of information carry flaunting advertisements of fake claims from these fraudulent healers who are practicing in open violation of the law. This has become so extensive with such support by some elements of the public press, by officers of the law, that the laws of California are being made a mockery.

No other law, even including the Eighteenth Amendment, is being so widely violated and disregarded as the Medical Practice Act, and these violations are causing more injury to the public and to the lives and health of individual citizens than the violation of all other laws put together.

These law breakers are now asking the people of California to support them in their law violation by making their illegal acts legal.

MORE ABOUT INSURANCE

The recent editorials in the California State Journal of Medicine have aroused extensive interest in the insurance world and are being broadcasted by the hundreds of thousands as reprints published and distributed by various insurance companies.

One result of this publicity has stimulated insurance companies that do not patronize the advertising pages of your own State Medical Journal or other medical journals to increase the volume of their "direct-by-mail advertising." The advertising columns of the California State Journal of Medicine are open to accredited insurance companies. All advertising matter of insurance companies in the columns of your Journal has been submitted to qualified, disinterested insurance specialists and bankers, and no advertisement is accepted by your publication that has not the full endorsement of those competent to judge insurance values.

Our members surely will make no mistake by patronizing insurance or other advertisers who have passed censorship and have purchased space in your own publication.

PROGRAM

THE FIFTY-FIRST ANNUAL SESSION OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA HELD AT YOSEMITE NATIONAL PARK, MAY 15, 16, 17, 18, 1922

OFFICERS AND COMMITTEES, 1922

John H. Graves, San Francisco, President.
H. G. Brainerd, Los Angeles, President-Elect.
Alfred C. Reed, San Francisco, First Vice-President.
Joseph Catton, San Francisco, Second Vice-President.
W. E. Musgrave, San Francisco, Secretary-Editor.
Hartley F. Peart, San Francisco, General Counsel.
Hubert T. Morrow, Los Angeles Assistant General Counsel.
Mr. Celestine J. Sullivan, Managing Editor.
Mr. William H. Barry, Superintendent of Publications.

COUNCILORS

First District—Paul M. Carrington, San Diego (1924)—San Diego, Riverside, Orange, San Bernardino, and Imperial Counties.

Second District — William H. Kiger, Los Angeles (1922)—Los Angeles, Santa Barbara, Ventura and Kern Counties.

Third District — T. C. Edwards, Salinas (1924)—San Luis Obispo and Monterey Counties.

Fourth District — Fred R. DeLappe, Modesto (1924)—Fresno, Kings, Tuolumne, Merced, Mariposa, Madera, Tulare and Stanislaus Counties.

Fifth District — Frank H. Paterson, San Jose (1923)—Santa Clara, San Mateo, San Benito and Santa Cruz Counties.

Sixth District—C. G. Kenyon, San Francisco, Chairman (1922)—San Francisco County.

Seventh District—Edward N. Ewer, Oakland (1923)—Alameda, Contra Costa, San Joaquin and Calaveras Counties.

Eighth District — James H. Parkinson, Sacramento (1922)—Sacramento, Amador, El Dorado, Alpine, Placer, Nevada Yuba, Sutter, Sierra, Yolo, Butte, Plumas, Lassen, Mono, Inyo, Glenn, Colusa, Tehama, Shasta, Modoc and Siskiyou Counties.

Ninth District—James H. McLeod, Santa Rosa (1923)—Marin, Sonoma, Lake, Mendocino, Solano, Napa, Del Norte, Humboldt and Trinity Counties.

Councilors-at-Large—O. D. Hamlin, Oakland (1922); Rene Bine, San Francisco (1923); George H. Kress, Los Angeles (1923); William T. McArthur, Los Angeles (1923); Saxton T. Pope, San Francisco (1924); C. Van Zwalenburg, Riverside (1923).

COMMITTEES

Committee on Scientific Program—W. E. Musgrave, chairman; Lemuel P. Adams, Oakland (1922); F. M. Pottenger, Monrovia (1923); F. F. Gundrum, Sacramento (1924); Walter V. Brem, Los Angeles (1925).

Publicity Committee—Mr. Celestine J. Sullivan, chairman; Alfred C. Reed, Donald J. Frick, Dewey R. Powell, J. R. Walker, Robert Pollock, Mr. O. Van Wyck, secretary.

Publicity Bureau — Rene Bine, chairman; John H. Graves, C. G. Kenyon, Hartley F. Peart, W. E. Musgrave.

Committee on Transportation and Hotels—Mr. H. H. Hunkins, chairman; James H. Parkinson, Morton Gibbons, Paul M. Carrington, T. C. Edwards, William H. Kiger, Mr. R. E. McCormick, secretary.

Auditing Committee—Rene Bine, Saxton T. Pope.

Committee on Industrial Accident Insurance Work—James H. Parkinson, chairman; John H. Graves, Gayle T. Moseley, Hartley F. Peart, W. E. Musgrave.

Assistant Secretaries for Convention — Edna L. Barney, H. A. R. Kreutzmann, Hans Schiffbauer, William W. Cross, Charles L. Bennett, Harlan Shoemaker, Barton Powell, T. M. McNamara, L. M. Coy, George J. Hall, George P. Worthington, W. E. Bates, Ferdinand Stabel, T. A. Card, Dan H. Moulton, E. P. Cook, W. D. Sansum.

GENERAL HEADQUARTERS AND MEETING HALLS

Diagrammatic map, showing location of various offices and meeting halls, will be distributed at Registration and Information desks. See also diagram, page 158.

(A) Secretary's office—Architect's office in Village.
(B) Registration Bureau—Sentinel Hotel Lobby in Village.
(C) Information offices — Yosemite Porch at Lodge, Sentinel Hotel Lobby in Village; Lobby at Camp Curry.
(D) Consolidated Ticket office—Transportation office at Lodge.
(E) Publicity Committee—Advertising room in Village.
(F) Council Room—Directors room in Village.

1. Convention Hall, seats 800, located in Village.
2. Church, seats 150, located in Village.
3. General Store, seats 250, located in Village.
4. Operating Office, seats 100, located in Village.
5. Auditor's Office, seats 100, located in Village.
6. Dining room, Sentinel Hotel, seats 150, located in Village.
7. Linen room, seats 150, located at Lodge.

(Letters and figures refer to locations shown on the map.)

GENERAL OUTLINE OF THE MEETINGS

There will be three sessions on Monday, Tuesday and Wednesday, and two sessions on Thursday.

Uniform hours for all meetings are provided for: 10 to 12:30; 2 to 4:30 p. m. and 8 to 10 p. m.

The places and time of all meetings are shown in the diagram.

General Sessions — Three general sessions have been arranged so that all persons may attend.

Section on Medical Economics, Education, Public Health and Hospitals—This section is held under the auspices of the League for the Conservation of Public Health. The time of this section meeting is so arranged that all may attend.

Section on Pathology and Bacteriology—Two meetings.

Section on Radiology, Roentgenology and Radium Therapy—Two meetings.

Section on Industrial Medicine and Surgery — Two meetings.

Section on Technical Specialties — This section includes: The California Association of Physiotherapists; The California Association of Radiographers; The California Association of Medical Social Workers; The California Association of Dietitians; The California Association of Laboratory Technicians.

Group of Medical Sections

Section on General Medicine—Four meetings, including one meeting devoted to tuberculosis.
Section on Pediatrics—Three meetings.
Section on Neuropsychiatry—Two meetings.

Group of Surgical Sections

Section on General Surgery—Three meetings.
Section on Eye, Ear, Nose and Throat—Two meetings.
Section on Urology—Two meetings.
Section on Orthopedic Surgery—Two meetings.
Section on Anesthesiology—One meeting.
Section on Obstetrics and Gynecology—Three meetings.

Council Meetings

All meetings of the Council will be held in the Board of directors' room of the Yosemite Transportation Company.

First Meeting—Monday, May 15, at 2 p. m.
Second Meeting—Tuesday, May 16, at 2 p. m.
Third Meeting—Wednesday, May 17, at 2 p. m.
Fourth Meeting—Thursday, May 18, at 2 p. m.

Meetings of the Council With the Presidents and Secretaries of Constituent Societies

There will be two of these important meetings, held in Hall No. 6 (Sentinel Dining Room). All members of the Council and all presidents and secretaries and as-

DIAGRAM SHOWING PLACES AND TIME OF ALL MEETINGS

DATE	HALL 1 Convention Hall	HALL 2 Church	HALL 3 General Store	HALL 4 Operating Office	HALL 5 Auditor's Office	HALL 6 Sentinel Dining Room	HALL 7 Sentinel Dining Porch	GENERAL HEADQUARTERS
Monday May 15 10–12:30	General Everybody Invited						This hall is reserved as a meeting place for any groups, committees, councils or other bodies who desire to have space for meetings.	
Monday May 15 2–4:30		General Medicine	Obstet. and Gyn.	Eye, Ear, Nose and Throat	Urology	Tech. Spec. General Meeting		Council
Monday May 15 8–10	House of Delegates			Radiology	Industrial Med. and Surg.	Section Anesthesiology		
Tuesday May 16 10–12:30	General Everybody Invited					Council and County Officers

Thursday May 18 2–4:30	Gen'l Med. Tuberculosis	General Surgery	Pediatrics	Radiology	Industrial Med. and Surg.			Council

sistant secretaries of constituent societies are requested to be present at these meetings.

First Meeting—Tuesday, May 16, at 11 a. m.
Second Meeting—Thursday, May 18, at 11 a. m.

Fraternal Meeting of Officers and Representatives of Western States Societies

An informal gathering of the Council and the representatives and fraternal delegates from other Western States for the discussion of problems of mutual interest. All persons included in this group are requested without further invitation to meet in Hall No. 1 (Convention Hall) on Tuesday, May 16, at 8 p. m.

HOUSE OF DELEGATES

The House of Delegates will hold two meetings.

Membership

Councilors—First District, Paul M. Carrington (1924); Second District, William H. Kiger (1922); Third District, T. C. Edwards (1924); Fourth District, Fred R. DeLappe (1924); Fifth District, Frank H. Paterson (1922); Sixth District, C. G. Kenyon (1922); Seventh District, Edward N. Ewer (1923); Eighth District, James H. Parkinson (1922); Ninth District, James H. McLeod (1923).

Councilors-at-Large—O. D. Hamlin (1922), Rene Bine (1923), George H. Kress (1923), William T. McArthur (1923), Saxton T. Pope (1924), C. Van Zwalenburg (1923).

FIRST MEETING OF HOUSE OF DELEGATES

Hall No. 1 (Pavilion) Monday, May 15, 8 p. m.

Order of Business

1. Calling to Order.
2. Roll Call.
3. Report of President.
4. Appointment of the Reference Committee by the President.
5. Report of the Council, by C. G. Kenyon, Chairman.
6. Report of the Committee on Scientific Program.
7. Report of the Auditing Committee.
8. Report of Committee on Expert Medical Testimony.
9. Report of Committee on Local and State Expenditures for Medical and Sanitary Measures.
10. Report of Committee on Codification of Constitution and By-Laws of the State Medical Society.
11. Report of Committee on Industrial Accident Insurance Work (Presented before the general sessions).
12. Report of the Secretary-Editor, W. E. Musgrave.
13. Unfinished Business.
14. New Business.
15. Reading and Adoption of Minutes.
    Adjournment.

SECOND MEETING OF HOUSE OF DELEGATES

Hall No. 1 (Pavilion) Wednesday, May 17, 8 p. m.

Order of Business

1. Calling to Order.
2. Roll Call.
3. Announcement of the Place of Meeting, 1923.
4. Election of Officers:
   (a) Election of President-Elect.
   (b) Election of First Vice-President.
   (c) Election of Second Vice-President.
   (d) Election of Secretary-Editor.
   (e) Election of Councilors:

   Second District—Incumbent, William H. Kiger (1922)—Los Angeles, Santa Barbara, Ventura, and Kern Counties.

   Fourth District—Incumbent, Fred R. DeLappe (appointed by Council to fill vacancy caused by resignation of D. H. Trowbridge, in accordance of Article V, Sec. 2 of by-laws) Fresno, Kings, Tuolumne, Merced, Mariposa, Madera and Stanislaus Counties.

   Sixth District—Incumbent, C. G. Kenyon (1922)—San Francisco County.

   Eighth District—Incumbent, James H. Parkinson (1922)—Sacramento, Amador, El Dorado, Alpine, Placer, Nevada, Yuba, Sutter, Sierra, Yolo, Butte, Plumas, Lassen, Mono, Inyo, Glenn, Colusa, Tehama, Shasta, Modoc, and Siskiyou Counties.

   At Large—O. D. Hamlin (1922).

   (f) Election of Member on Program Committee (four years)—Incumbent, Lemuel P. Adams (1922).

   (g) Election of one Delegate to A. M. A. (four authorized)—Incumbents: Bert Ellis (1922), Albert Soiland (1922), John H. Graves (1922).

   (h) Election of one Alternate to A. M. A. (four authorized)—Incumbents: C. Van Zwalenburg (1922), Edward N. Ewer (1922), E. C. Fleischner (1922).
5. Report of Reference Committee.
6. Presentation of President.
7. Presentation of President-Elect.
8. Reading and Adoption of Minutes.
   Adjournment.

GENERAL INFORMATION

General headquarters will be at and near the Sentinel Hotel.

The offices of the President, President-Elect, Council and Committees will be at general headquarters.

The office of the State Secretary and Assistant Secretaries will be at headquarters.

A number of assistant secretaries have been appointed for the Convention. Among other duties, one of them will make contact with the chairman and secretary of each section for such assistance with the program and other problems as it is possible to give.

Headquarters of the League for the Conservation of Public Health will be a part of general headquarters.

Registration—The registration desk is located in the lobby of the Sentinel Hotel. All persons, whether members or not, are requested to register as soon as they arrive in Yosemite. Beginning Sunday, May 14, registration secretaries will be on duty daily from 9 a. m. until 4 p. m.

Information—One information desk will be maintained in the lobby of the Sentinel Hotel; one at Yosemite Lodge porch, and another in the lobby at Camp Curry.

Railroad Tickets—The San Francisco and Oakland Terminal lines and the Yosemite Transportation Company will maintain a consolidated ticket office at Yosemite Lodge Transportation office. All questions regarding tickets or transportation should be taken up with this office.

Guests and Visitors—All guests and visitors are requested to register. All scientific meetings are open to visitors and guests.

Badges—Two kinds of badges will be issued by the registration bureau. All members of the State Society will be issued the usual membership badge. A special badge will be issued to all guests and fraternal delegates who are attending the meetings upon official invitation of the Society.

Ribbons for Delegates and Alternates—The usual official ribbon is provided for this purpose and will be issued to all persons authorized to wear it.

Membership Cards—Every member in good standing in the California State Medical Society has been issued an official membership card for 1922. This card may be useful in connection with railroad tickets, and all members are requested to have their cards with them.

Suggestions and Constructive Criticism—The officers and committees have tried to do everything possible to

make the meeting a success. Suggestions and constructive criticism calculated to make future meetings more useful will be welcomed by any of the officers or by the Publicity Committee. Complaints of whatever character should be made to the Publicity Committee.

The A. M. A. Meeting at St. Louis. All persons desiring to go to the A. M. A. meeting at St. Louis should get in touch with the Committee on Transportation and Hotels at Yosemite Lodge as soon as possible after arrival in Yosemite. If 125 or more desire to make this trip and make their wishes known to the committee before Wednesday at noon, a special train (the California State Medical Society Special) may be arranged for.

Social Program—No set social program has been arranged. The unusual attractions of Yosemite are believed to make this inadvisable. It is hoped that members and guests will form their own social contacts for sports, dinners, hiking and visits to places of interest. The program has been arranged so as to allow much time for amusement and recreation. There are no meetings before 10 a. m. and none between 12:30 and 2 p. m., and none between 1:30 and 8 in the evening.

Hospital. The Yosemite Hospital is located near Yosemite Lodge. Dr. Frederick Stein, who is in charge of the hospital, states that physicians and nurses are on duty at all hours.

Bus Line—The Yosemite Transportation System will maintain an adequate "street car" service between all meeting places of the various sections and the various hotels, including Camp Curry and the Lodge. The fare between any two points is 10 cents.

Press Representatives—Accredited press representatives are welcome and they will be accorded every possible courtesy. Press headquarters will be in the office of the Committee on Publicity.

Publicity—All publicity is in the hands of the Publicity Committee. It is requested that all persons having matter of "news" value report it to this committee. It is particularly requested that all "news" about any phase of the convention be given out through the official committee and in no other way.

Exhibits—After mature deliberation by the Council and the Publicity Bureau it has been decided that no exhibits will be authorized or permitted. Accredited representatives of firms recognized in the advertising columns of the "Journal" and "Better Health" will be accepted as accredited visitors to the convention and authorized to solicit members and guests. All such representatives will be issued cards by the Secretary upon application.

Daily Bulletin. Mr. W. H. Barry, Superintendent of Publications of the State Society, will publish a daily bulletin during the four days of the meeting. The Bulletin will be issued every morning between 10 and 12:30 during the time the general sessions are holding their meetings. Items for the "Bulletin" should be left with the Publicity Committee or at any information desk.

Social Hosts—One of our members will be assigned as host to each of our invited guests. These assignments will be made at the Registration Bureau.

Rules Regarding Papers and Discussions at the State Meeting—Upon recommendation of the Publicity Bureau the following rules regarding papers have been adopted by the Council:

1. The maximum time that may be consumed by any paper is fifteen minutes, provided that not to exceed ten minutes' latitude may be allowed invited guests at the discretion of the presiding chairman.

2. Motions from the floor to extend the time of an author may not be entertained by the presiding officer.

3. The maximum time permitted any individual discussant on any paper is four minutes. This also applies to the author in closing his discussion. No discussant may speak more than once upon the same subject.

4. A copy of each and every paper presented at the State meeting must be in the hands of the chairman or secretary of the section or in the hands of the general secretary before the paper is presented.

5. Manuscript not accepted by the Publicity Bureau for publication in the Journal will be returned to the author as soon as practicable. Authors desiring to publish their paper elsewhere than in the Journal may have their manuscript returned to them upon written request to the State Secretary.

6. No paper will be accepted by the General Program Committee nor by Section Program Committees unless accompanied by a synopsis of not to exceed 50 words.

7. Papers shall not be "read by title."

8. No member may present more than one paper at any one State meeting, provided that members may present additional papers before Sections on Technical Specialties; and provided further, that a member may be a collaborator on more than one paper, if these papers are presented by different authors.

9. Failure on the part of an author to present a paper precludes acceptance of future papers from such author for a period of two years, unless the author explains to the satisfaction of the Publicity Bureau his inability to fulfill his obligation.

GENERAL SESSIONS

JOHN H. GRAVES, M. D., President,
977 Valencia Street, San Francisco.

W. E. MUSGRAVE, M. D., Secretary,
912 Butler Building, San Francisco.

FIRST MEETING

Hall No. 1 (Convention Hall), Monday, May 15, 10 a. m.

1. *President's Annual Address*—John H. Graves, M. D., 977 Valencia Street, San Francisco.
2. *The Contributions of Vivisection to Public Welfare*—Karl F. Meyer, Hooper Foundation, San Francisco.
3. *Women Physicians and the Program of Better Medicine and Better Public Health*—May E. Walker, M. D., Oakland Bank of Savings Bldg., Oakland.
4. *The Problems of Industrial Accident Insurance*—James H. Parkinson, M. D., 1601 I Street, Sacramento.
   Report of the Committee of the Council of the State Society, with comments by the chairman.
5. *Some Problems of Medical and Indemnity Defense*—Hartley F. Peart, Humboldt Bank Building, San Francisco.
6. *The Neuropsychiatry Problem*—Walter T. Williamson, M. D., Corbett Building, Portland, Oregon.

SECOND MEETING

Hall No. 1 (Convention Hall), Tuesday, May 16, 10 a. m.

ALFRED C. REED, M. D., First Vice-President,
350 Post Street, San Francisco.

EDNA L. BARNEY, M. D., Assistant Secretary,
Children's Hospital, San Francisco.

1. *The Place of Pathology in the Practice of Medicine*—Walter V. Brem, M. D., Pacific Mutual Building, Los Angeles.
2. *Medical Education of the Present and of the Near Future*—Ray Lyman Wilbur, M. D., Stanford University, Palo Alto.
3. *The Place of the Clinician in Medicine of the Future*—Herbert C. Moffitt, M. D., Schroth Building, San Francisco.
4. *The Diagnostic and Prognostic Value of the Breath-Holding Test*—F. H. McMechan, M. D., Avon Lake, Ohio.
5. *What Is Meant by the Psychoneuroses*—Joseph H. Collins, M. D., 35 W. 54th Street, New York City, New York.
6. *What the General Practitioner Can Do to Improve Maternity Conditions*—Reginald K. Smith, M. D., 391 Sutter Street, San Francisco.

THIRD MEETING

Medical Economics, Education, and Hospitals

This Section is under the auspices of *The League for the Conservation of Public Health.*

DUDLEY SMITH, M. D., President,
Oakland.

W. T. MCARTHUR, M. D., Secretary,
Los Angeles.

GENERAL MEETING

Hall No. 1 (Convention Hall), Wednesday, May 17, 10 a. m.

1. *Progress and Problems of Public Health Work*—Walter M. Dickie, M. D., Secretary California State Board of Health.
2. *Hospital Betterment in California*—Percy T. Magan, M. D., Medical Secretary Seventh Day Adventist General Conference Pacific Coast States.
3. *Insidious Issues of 1922*—Celestine J. Sullivan, Executive Secretary League for the Conservation of Public Health.

4. *The Contribution of Modern Medicine to Commerce*—Hon. John D. Fredericks, President Los Angeles Chamber of Commerce.
5. *Guarding the Health of Our Citizens*—Hon. James Rolph, Jr., Mayor of San Francisco.

FOURTH MEETING

Hall No. 1 (Convention Hall), Thursday, May 18, 10 a. m.

JOSEPH H. CATTON, M. D., Second Vice-President, 209 Post Street, San Francisco.

HANS E. SCHIFFBAUER, M. D., Assistant Secretary, Title Insurance Building, Los Angeles.

1. *Address of President-elect*—Henry G. Brainerd, M. D., Brockman Building, San Francisco.
2. *The Duties of the General Practitioner in the Anti-Tuberculosis Program*—Charles J. Minor, M. D., Asheville, North Carolina.
3. *Medical and Health Programs of Organized Industries*—Walter B. Coffey, M. D., Medical Building, San Francisco.
4. *The Problems and Practice of "Group Medicine"*—Donald J. Frick, M. D., Van Nuys Building, Los Angeles.
5. *Outstanding Features of Recent Progress in Surgery*—George Thomason, M. D., Hollingsworth Building, Los Angeles.
6. *What the General Practitioner Can Do to Improve the Diagnosis and Treatment of Diseases of Children*—Robert Langley Porter, M. D., Sehroth Building, San Francisco.

PATHOLOGY AND BACTERIOLOGY SECTION

WILLIAM OPHULS, M. D., Chairman, Stanford Medical School, San Francisco.

ROY W. HAMMACK, M. D., Secretary, Brockman Building, Los Angeles.

FIRST MEETING

Hall No. 1 (Convention Hall), Tuesday, May 16, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *The Effect of X-ray Upon the Structure and Bacterial Flora of the Tonsils*—F. R. Nuzum, M. D., Cottage Hospital, Santa Barbara.
3. *A Clinical and Pathological Study of Fifty Cases of Hyperthyroidism*—R. B. Hill, M. D., Merchants National Bank Building, Los Angeles.
4. *Germanium Dioxide and Erythropoiesis*—W. T. Cummins, M. D., San Francisco Hospital, San Francisco.
5. *Some Limitations on the Agglutination Reaction in the Identification of Sporulating Anaerobes*—Ivan C. Hall, Ph. D., Berkeley.

SECOND MEETING

Hall No. 1 (Convention Hall), Wednesday, May 17, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.

Symposium on Coccidioidal Granuloma

2. *A Report of Cases of Coccidioidal Granuloma with Especial Reference to Meningeal Involvement*—Ernest C. Dickson, M. D., Stanford Hospital, San Francisco.
3. *Coccidioides Immitis as a Cause of Meningitis with Hydrocephalus*—Glanville Y. Rusk, M. D., Hooper Foundation, San Francisco.
4. *A Report of Cases of Coccidioidal Granuloma Observed in Southern California*—Roy W. Hammack, M. D., Brockman Building, Los Angeles; J. Mark Lacey, M. D., Auditorium Building, Los Angeles.
5. *Torula Infection*—Newton G. Evans, M. D., Loma Linda.
6. *Lethargic Encephalitis*—N. T. McArthur, M. D., Napa State Hospital, Imola.

RADIOLOGY SECTION

(Including Roentgenology and Radium Therapy)

ALBERT SOILAND, M. D., Chairman, 1407 S. Hope Street, Los Angeles.

H. E. RUGGLES, M. D., Secretary, Butler Building, San Francisco.

FIRST MEETING

Hall No. 4 (Operating Office), Monday, May 15, 8 p. m.

1. Chairman's Address and Secretary's Report.
2. *Recent Progress in Radio-Therapy* (Illustrated with lantern slides)—Rex D. Duncan, M. D., 1151 W. 6th Street, Los Angeles.

   Modern methods in application of radium with illustrative cases.
3. *Deep Therapy*—John M. Rehfisch, M. D., 391 Sutter Street, San Francisco.

   Limitations of previous apparatus for intensive radiation.

   Personal experience with new 300,000 volt transformer.
4. *The Physical Basis of Modern Roentgen Therapy*—Mr. Frank Rieber, 693 Mission Street, San Francisco.

   Importance of knowledge of fundamental physical facts in design and use of apparatus for intensive therapy. Current fallacies concerning measurement of electrical factors in Roentgen ray work.
5. *Diagnosis of Cases with So-called Pathological Gall-Bladder Symptoms*—Caro W. Lippman, M. D., Butler Building, San Francisco.

SECOND MEETING

Hall No. 4 (Operating Office), Thursday, May 18, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Gastric Ulcer Complicated by Jejunal Ulcer*—Lloyd B. Crow, M. D., 391 Sutter Street, San Francisco.

   Object of reporting cases. Detailed reports of two cases.
3. *Enteroliths*—W. W. Boardman, M. D., 350 Post Street, San Francisco.

   Comparative rarity of condition; importance of thorough examination; case reports.
4. *Measurements Based Upon Roentgen Examination of 100 Normal Children*—Elizabeth Schulze, M. D., University California Hospital, San Francisco.

   Attention directed to sphenoidal angle by Pacini in 1921; survey of 100 normal children in effort to check his results; normal sphenoidal angle found to be considerably larger than figures given by Pacini; other measurements.
5. *Roentgen Examination of Chests in Children*—Orrin S. Cook, M. D., Flood Building, San Francisco.

   Lobar and bronchopneumonia in children; difference between their appearance in children and adults; atypical effusions and empyemas; tuberculosis in children—lung tumors.
6. *Diverticula of the Cardiac End of the Stomach*—Chas. M. Richards, M. D., Garden City Bank Building, San Jose.

   Rarity of condition; symptomatology; report of cases.

   General demonstration of lantern slides. Members are urged to bring slides of interesting cases for informal discussion.

INDUSTRIAL MEDICINE AND SURGERY SECTION

E. W. Cleary, M. D., Chairman,
177 Post Street, San Francisco.

Packard Thurber, M. D., Secretary,
906 Black Building, Los Angeles.

FIRST MEETING

Hall No. 5 (Auditor's Office), Monday, May 15, 8 p. m.

1. Chairman's Address and Secretary's Report.
2. *An External Bridge for the Fixation of Compound Fractures*—Charles A. Dukes, M. D., Central Bank Building, Oakland.

   History; difficulties in mechanical device; dangers of infection; a simplified plate easy of mechanical adjustment, readily attainable and adaptable to any type of long bone fracture; report of cases.

   Discussion opened by George Rothganger, M. D., 1501 San Pablo Avenue, Oakland, and Alvin Powell, M. D., 3105 Grove Street, Oakland.
3. *The Necessity for More Accurate Data in the Surgeon's Permanent Disability Report*—Frank E. Raynes, M. D., 240 Stockton Street, San Francisco.

   Attention invited to letter of instructions from Industrial Accident Commission; necessity of uniformity; necessity of full and accurate measurements for lost function; necessity of accurate record of occupation when hurt, age and wages; permanent disability rating is not applicable while improvement in function can be obtained by treatment.
4. *A New Method of Treating Fractures of the Carpal Scaphoid*—T. J. Nolan, M. D., Flood Building, San Francisco.
5. *Resection of the Distal End of the Ulna to Compensate for Shortening of the Radius Following Fracture*—Carl L. Hoag, M. D., 177 Post Street, San Francisco.

   Preliminary Report of a Simple and Effective Treatment for a Common and Serious Disability. Lantern Slides.

   Fracture of the radius with shortening results in characteristic changes at the wrist, whether the fracture is in the shaft or at the distal end; these changes are apparently due to the resulting disproportion in the length of the two bones, and consist of a protrusion of the ulna into the carpal region, and loss of strength and limitation of range of motion, especially in the wrist. Findings at operation suggest that there is also a fracture of the triangular cartilage between the radius and ulna at time of injury. Removal of the distal end of the ulna re-establishes the length-relations between radius and ulna, and the soft parts with their undisturbed attachments to the periosteum, quickly readjust themselves. Selection of cases; technique and after-care.
6. *Industrial Medicine and the General Practitioner*—Gayle G. Moseley, M. D., 333 Pine Street, San Francisco.

SECOND MEETING

Hall No. 5 (Auditor's Office), Thursday, May 18, 2 p. m.

1. Election of Section Officers and the Transaction of Other Section Business.
2. *The Conservative Treatment of Fractures of the Elbow Joint*—Edgar L. Gilcreest, M. D., Hahnemann Hospital, San Francisco.

   Points in the anatomy of the elbow joint; movements of the elbow joint; classification of fractures of the elbow joint; treatment; conservative versus operative or open reduction, with advantages of each method and disadvantages of each method; flexion versus traction; necessity for frequent X-ray controls.
3. *So-called "Chauffeur's Fractures"*—Philip Stephens, M. D., Pacific Electric Building, Los Angeles.

   Incidence of fracture about the wrist or forearm, due to automobile cranking; direction of force, and its variation as a causation of different lesions produced; age; character of bones fractured as factor in prognosis and estimating loss of time in these injuries; reduction and treatment; when should they be released for duty; the cases in which there is bone shortening on the radial side, and result in a certain amount of deformity and function loss.
4. *The Necessity for an Immediate and Thorough Roentgenological Study of All Injuries to the Spine*—H. W. Chappel, M. D., 134 S. Norton Avenue, Los Angeles.
5. *Fractured Pelves, with Particular Reference to Dislocation of Sacro-iliac Synchondrosis*—Harlan Shoemaker, M. D., Marsh-Strong Building, Los Angeles.
6. *Physiotherapy Treatment*—Arthur R. Gould, M. D., 291 Geary Street, San Francisco.

   Standardization of treatment; surgical cases; diagnosis of (a) surgeon and (b) physiotherapist; time from injury to treatment; object of physiotherapy treatment; types of treatment; mention of uses in medical cases.
7. *Misuse of the Industrial Accident Fee Schedule*—Morton R. Gibbons, M. D., 350 Post Street, San Francisco.

   Fees charged and collected for similar services are not uniform; rebates; contracts; flat rates; under-charge; failure to apply modifying clauses for unusual service; forcing minimum fees; necessity for all physicians and surgeons to know proper charges and co-operate to collect them; function of California State Medical Society; clearing house or fee bureau to secure uniform charges; result will be enlarged panels, larger collections; decline of contract and salary practice.

TECHNICAL SPECIALTIES SECTION

Ray Lyman Wilbur, M. D., Chairman,
Stanford University, Palo Alto.

Charles T. Sturgeon, M. D., Secretary,
Merritt Building, Los Angeles.

FIRST MEETING

Hall No. 6 (Sentinel Dining Room), Monday, May 15, 2 p. m.

All members of the California Association of Physiotherapists; the California Association of Radiographers; the California Association of Medical Social Workers; the California Association of Dieticians; the California Association of Laboratory Technicians, and all other persons interested in the technical specialties are invited to attend this meeting.

1. Chairman's Address.
2. *The Technical Specialty Organizations*—Hartley F. Peart, General Counsel for the State Medical Society, Humboldt Bank Building, San Francisco.
3. Election of Section Officers.

SECOND MEETING

Hall No. 6 (Sentinel Dining Room), Wednesday, May 17, 10 a. m.

California Association of Physiotherapists

Hazel Furscott, President,
Hahnemann Hospital, San Francisco.

Florence E. Atkinson, Secretary,
29 Mosswood Road, Berkeley.

1. *Educational Standards in Physiotherapy*—Ray Lyman Wilbur, M. D., President Stanford University, Palo Alto.

2. *The Effect of Massage, Heat, and Exercise on the Local Circulation*—A. W. Hewlett, M. D., Lane Hospital, San Francisco.
3. *Early Physiotherapy Treatment of Fractures*—Walter I. Baldwin, M. D., Butler Building, San Francisco.
4. *The Standardization of Physiotherapy Equipment*—Miss Myrna Howe, Physiotherapy Technician, Butler Building, San Francisco.
   Classification and description of different types of equipment; reduction of equipment to that most successfully used and necessary for a physiotherapy department in:—an orthopedic surgeon's office engaged in private practice; an orthopedic surgeon's office engaged in private practice plus industrial work and in a hospital clinic.
5. *Physiotherapy Records*—Miss Hazel E. Furscott, Physiotherapy Technician, University of California Hospital, San Francisco.
   A working method of making physiotherapy records of progress; range of motion, graphic, mechanical; circumferential; strength; normal measurements and their variations. The value of adequate records to the patient, to the technician, to the physician. Statistics from these records and their possible contribution to physiotherapy and medicine.
6. Business Meeting.

THIRD MEETING

Hall No. 6 (Sentinel Dining Room), Wednesday, May 17, 2 p. m.

California Association of Medical Social Workers

Miss Eleanore Stockton, President, Board of Health, San Francisco.

Miss Edna J. Shirpser, Secretary, Children's Hospital, San Francisco.

1. *Child Welfare Centers Under Supervision of the Department of Public Health*—Miss Eleanore Stockton, Board of Health, San Francisco.
2. *Medical Social Service in the Hospital*—Miss Marguerite Wales, Stanford Medical School, San Francisco.
3. *The Relationship of Social Service to the Medical Profession*—Ray Lyman Wilbur, M. D., Stanford University, Palo Alto.
4. *The Place of Medical Social Service in Hospital Organization and the Duties of Medical Social Workers Toward Hospital Administration*—Frank R. Nuzum, M. D., Cottage Hospital, Santa Barbara.
5. Social and Economic Diagnosis—General discussion.
6. Business Meeting.

GENERAL MEDICINE SECTION

Joseph King, M. D., Chairman, Brockman Building, Los Angeles.

E. S. Kilgore, M. D., Secretary, 391 Sutter Street, San Francisco.

FIRST MEETING

Hall No. 2 (Church), Monday, May 15, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *Diphtheria—A Controllable and Preventable Disease*—W. W. Roblee, M. D., Riverside.
   Recent increase of diphtheria in California; report of control measures used at Sherman Institute Indian School, Riverside, in two epidemics from separate foci; experience with Schick test and toxin-antitoxin administration; relative importance of: (1) quarantine, (2) detection and elimination of carriers, (3) detection and elimination of non-immunes.
3. *Treatment of Hypertension*—D. D. Comstock, M. D., White Memorial Hospital, Los Angeles.
   Summary of known facts about hypertension; classification—symptomatic, essential or idiopathic. A study of the latter, with reference to diet and metabolism; evidences of organic and of functional factors; detailed outline of treatment for a case of essential hypertension, with discussion.
4. *The Surgical Treatment of Angina Pectoris*—Philip King Brown, M. D., Medical Building, San Francisco; Walter B. Coffey, M. D., Medical Building, San Francisco.
   The theory of angina and the problem involved. The resection of the cervical sympathetic system in part or whole. The work of Francois-Franck in 1896 on aortitis and the cervical sympathetic in relation to angina and his suggestion that sympathectomy be tried in the treatment. The work of Jaboulet and his pupils, especially Lariche, on the effects of destroying the sympathetic nerve supply to blood vessels. The operation for the relief of angina successfully done by Janesco in 1916. The report of cases operated on in the Southern Pacific Hospital with cardiograms, tracings and dissections.
   Discussion by A. W. Hewlett, M. D., Lane Hospital, San Francisco.
5. *Present Status of Quinidin Therapy*—A. W. Hewlett, M. D., Stanford Medical School, San Francisco.
   Quinidin sulphate for the purpose of restoring a normal heart rhythm in patients with auricular fibrillation. Mode of administration, results and dangers. Review of the literature and personal experiences.
6. *The Diagnosis and Treatment of Cardio-Vascular Conditions in Thyroid Disease*—William J. Kerr, M. D., University of California Medical School, San Francisco; George C. Hensel, M. D., University of California Hospital, San Francisco.
   The frequency of cardio-vascular symptoms and signs in exophthalmic goiter; the relative infrequency in toxic adenoma; the nature of the cardio-vascular changes; the methods of recognition of these abnormalities. Pre-operative and post-operative treatment illustrated with polygraph tracings and electrocardiograms.

SECOND MEETING

Hall No. 2 (Church), Tuesday, May 16, 2 p. m.

1. *Inflammation of the Bowels*—S. A. Livatte, M. D., Santa Ana.
   Retrospective; presumptive; negatively pathognomonic; some modern fallacies; entender la chanza; bibliography.
   Discussion opened by Saxton Pope, M. D., Butler Building, San Francisco.
2. *Is the Meltzer-Lyon Technic an Asset or a Liability*—Walter C. Alvarez, M. D., 177 Post Street, San Francisco.
   If it will help in the diagnosis and treatment of gall-bladder disease it is an asset. If failing in that, it fosters the tendency of physicians to waste the time and money of patients who should promptly be turned over to the surgeon, it is a liability. The method is founded on theory and not on fact. Recent observations tend to discredit the theory. Apparently the magnesium sulphate does not tend to empty the gall-bladder. The use of the tube is not necessary, as magnesium sulphate and other drugs will increase the flow of bile when given by mouth. A large proportion of diseased gall-bladders have no stones and a clear, sterile bile. The infection is in the wall. Cholecystectomy should be done before the patient becomes a poor surgical risk.
3. *Chronic Arthritis*—Leonard W. Ely, M. D., Stanford Medical School, San Francisco.
   Further studies on the great second type of the disease. Therapeutic applications and remarks on classification.
4. *Evidence of the Presence of Amebae in Bone Lesions of Arthritis*—Charles A. Kofoid, Ph. D., and

Olive Sweezy, Ph. D., University of California, Berkeley.

5. *Non-Dysenteric Amebiasis*—Alfred C. Reed, M. D., 350 Post Street, San Francisco.

Frequency of amebiasis. Common clinical association of symptoms with it. Rarity in California of dysentery as a symptom and frequency of constipation. Unreliability of references to amebae outside of gastro-intestinal tract in man. Question of amebae in liver and bile tract. Relation of amebae to non-infective (non-bacterial) bone lesions. Amebia gingivalis not pathogenic. Clinical relationship of arthritis deformans (type II Ely), and ameba. Treatment of amebiasis, and its difficulty.

Discussion by John V. Barrow, M. D., Investment Building, Los Angeles; Herbert Gunn, M. D., 350 Post Street, San Francisco.

THIRD MEETING

Hall No. 2 (Church), Wednesday, May 17, 8 p. m.

1. Election of Section Officers and Transaction of Section Business.

2. *The Treatment of Constipation*—R. Manning Clarke, M. D., San Marcos Building, Santa Barbara.

Hypertonic and atonic types, and interrelations of these. Etiology; role of cathartics, enemas, foods, psychic disturbances; symptoms-theories of toxic absorption or nerve irritation; treatment-avoidance of irritation from bulky food, cathartics, enemas, nerve strain; value of bed rest; medication.

3. *Associated Syphilis and Tuberculosis*—A. L. Bramkamp, M. D., Banning.

Prevalence of each disease separately; prevalence of the two in association; consideration of the pathology of the two diseases; primary and secondary syphilis and the effect of tertiary syphilis on the course of the other when in association; treatment of the two diseases when associated in the same individual.

4. *Intra Vitam Bone Marrow Puncture in Pernicious Anemia*—Ernest H. Falconer, M. D., Physicians Building, San Francisco.

Description of drill devised by L. M. Morris, M. D., for performing marrow puncture of long bones, also brief description of technique; in what way can this procedure be applied to study of pernicious anemia? Theories about pathology and bone marrow changes in pernicious anemia; lantern slides of actual smears of bone marrow from different types of cases of pernicious anemia; consideration of data obtained from cases of primary anemia where marrow puncture has been performed; discussion of problems opened for study by this method.

5. *Polycythemia Vera and Its Treatment*—Stewart V. Irwin, M. D., Dalziel Building, Oakland.

Résumé of 250 cases; definition; symptomatology; physical signs; blood picture; course of disease; errors in diagnosis; pathology and physiology; treatment based on experimental and clinical observations; radium, where and how used; benzol, its place in treatment; cases treated by newer method and results obtained.

6. *The Effect of Feeding Gliadin on the Growth of Carcinoma in White Rats*—R. A. Kocher, M. D., Timken Building, San Diego.

Recent experiments on normal growth in animals have established that growth is not proportional to the quantity of protein in the diet, but is rather dependent on the proportion of certain of the amino-acid constituents of the protein molecule. Chief of these so-called "growth amino-acids" is lysine. Lysine is not a requirement for the maintenance of the adult animal, but is purely a "growth-factor." The present experimental work is carried out on adult white rats with carcinoma, to determine what effect a diet adequate for maintenance of the host, but deficient in lysine, would have on the growth and metastasis of the tumor. Tables and curves of growth of the tumors and metastases in experimental and control animals will be shown.

FOURTH MEETING

Hall No. 1 (Convention Hall), Thursday, May 18, 2 p. m.

This meeting devoted entirely to tuberculosis.

1. *Periodic Variations in Basal Metabolic Rate in Tuberculous Patients*—Philip H. Pierson, M. D., Physicians Building, San Francisco.

Does a variation occur? If so, what relation does it bear to menstruation or other factors? Is there any relationship between this variation and the activity of the disease.

2. *Gastro-Intestinal Complications with Pulmonary Tuberculosis*—Wm. C. Voorsanger, M. D., 177 Post Street, San Francisco.

Regulated feeding as distinguished from simple overfeeding. Difficulties in feeding which arise from gastro-intestinal disorders, either functional or organic—e. g., anorexia, vagaries of appetite, distress after eating, nausea and vomiting, coughing during eating, abdominal pain, result of overeating, diarrhea, gastric or duodenal ulcer, colitis, appendicitis, intestinal tuberculosis. Differential diagnosis is to be discussed; and in connection with treatment the use of calcium clorid intravenously to combat anorexia and increased peristalsis.

3. *Experience with Thoracoplasty in Tuberculosis*—Ralph C. Matson, M. D., Portland, Oregon.

4. *The Sanatorium Treatment of Tuberculosis*—W. Jarvis Barlow, Security Building, Los Angeles.

Position occupied by sanatoria in the campaign against tuberculosis; sanatorium treatment as it was and is today; difficulties encountered. Why has sanatorium treatment not been more successful? Type of institutions of most value; results of cases treated; follow-up work.

5. *The Use of Opiates in Pulmonary Hemorrhage of the Tuberculous*—Charles A. Browning, M. D., Merritt Building, Los Angeles.

Discussion of the indications to be met by opiates in pulmonary hemorrhage; discussion of unfavorable influence of opiates on patients; immediate; morale; remote; pneumonia; opium habit.

PEDIATRICS SECTION

WILLIAM P. LUCAS, M. D., Chairman
University Hospital, San Francisco.

HUGH K. BERKLEY, M. D., Secretary,
Brockman Building, Los Angeles.

FIRST MEETING

Hall No. 3 (General Store), Tuesday, May 16, 8 p. m.

1. Chairman's Address and Secretary's Report.

Symposium on the Pirquet "Nem" System of Feeding.

2. *The Origin and Application of the Pirquet System of Child Feeding, Under the Hoover Relief Administration of Austria*—Herbert S. Coulter, M. D., 1949 Huntington Drive, Pasadena.

3. *The Reliability of the Sitting Height as an Index to Nutrition*—Harold K. Faber, M. D., Lane Hospital, San Francisco.

4. *The Pirquet System and American Requirements*—Wm. E. Carter, M. D., University Hospital, San Francisco.

SECOND MEETING

Hall No. 3 (General Store), Wednesday, May 17, 2 p. m.

Symposium on the Recently Prevalent Acute Infectious Diseases of the Nervous System in Childhood (Epidemic Encephalitis, Acute Polio-Myelo-Encephalitis).

1. *Epidemiology, Pathology*—William P. Lucas, M. D., University Hospital, San Francisco.
2. *Clinical Aspects and Differential Diagnosis*—Rachel L. Ash, M. D., University Hospital, San Francisco; Langley Porter, M. D., 240 Stockton Street, San Francisco.

General Discussion. Because of the importance of the subject, the papers will be thrown open at once for general discussion, so that the characteristics of these conditions may be fully considered by the members of the section.

THIRD MEETING

Hall No. 3 (General Store), Thursday, May 18, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.

Symposium on Posture in Childhood.

2. *The Etiology and Treatment of Faulty Posture in Children*—John C. Wilson, M. D., Baker-Detwiler Building, Los Angeles.
3. *Posture as Related to Nutrition in Children*—Alfred Edward Meyers, M. D., 350 Post Street, San Francisco.
4. *Posture in Its Relation to Health*—Howard Markel, M. D., Butler Building, San Francisco.
5. *Physiotherapy in the Treatment of the Child with Rheumatic Infection*—Edith Bronson, M. D., 240 Stockton Street, San Francisco.
6. *Influence of the Eyes on Posture in Torticollis*—Percival Dolman, M. D., Flood Building, San Francisco.

Demonstration of methods of correcting postural defects will be given in connection with the above papers by Miss Gwendolyn Bovill, Physiotherapist, University Hospital, San Francisco.

NEUROPSYCHIATRY SECTION

WALTER F. SCHALLER, M. D., Chairman,
Medical Building, San Francisco.
W. B. KERN, M. D., Secretary,
Brockman Building, Los Angeles.

FIRST MEETING

Hall No. 4 (Operating Office), Tuesday, May 16, 8 p. m.

1. Chairman's Address and Secretary's Report.
2. *Constitutional Psychopathic Inferiority*—William House, M. D., Selling Building, Portland, Oregon.

   The term Constitutional Psychopathic Inferiority is applicable to a vast number of persons, possibly as many as 10 per cent of the total population. From this group are derived in all probability as many victims of the psychoneuroses and insanities as from the entire balance of the population. They furnish the recruits from whom not only neurological but general medical and surgical practice is drawn. The general types may be recognized, the one sluggish, dull and made up of people able to do fair work under certain restrictions, the other often incorrigible and easily led into criminal ways. Both types exert detrimental influences in school, social, military and industrial life. Etiologically hereditary and possibly endocrine deficiencies are influential. The recognition of these types has a profound bearing on medical, social and economic life and better understanding of them is of great practical as opposed to purely theoretical value.

   Discussion opened by Norbert J. Gottbrath, M. D., Flood Building, San Francisco.
3. *The Use of the Pupilloscope in Neurology*—Henry G. Mehrtens, M. D., Lane Hospital, San Francisco; Otto Barkan, M. D., 516 Sutter Street, San Francisco.

   Its possible use in syphilis without positive spinal fluid findings; in neuro-syphilis with positive findings; in arrested or burnt out neuro syphilis; in cases of doubtful diagnosis.
4. *A Study of the Relation of Low Basal Metabolism Rates to Fatigue States*—Roland S. Cummings, M. D., Pacific Mutual Building, Los Angeles.

   A review of 100 subjects having a basal metabolism rate of 10 per cent or below; a review of 50 subjects having a normal basal metabolism rate (between plus and minus 10); 33 per cent of cases with basal metabolism rates below normal had a clinical diagnosis of fatigue neurosis; 15 per cent of all subjects with normal rates had a clinical diagnosis of fatigue neurosis; only 5 per cent of patients with a low rate had normal endurance and normal energy; 50 per cent of all patients with normal rates had normal energy and endurance; a very small percentage of patients with normal rates complained of marked fatigue, while the majority of patients with a low rate did complain of marked fatigue, fatigue symptoms always being accompanied by general nervousness; a discussion of other signs of a hypothyroid state which were present in this group; a discussion of the causes of fatigue states and the general nervous symptoms in their relation to the causes of the low basal metabolism rate.
5. *The Alienist and Expert Testimony*—Edward Huntington Williams, M. D., Brockman Building, Los Angeles.

   A summary of the faults of existing methods of taking expert testimony; reasons for the attitude of the public; some reasons why a more rational system has not been adopted; some suggestions for a change for the better.
6. *Post Infectious Encephalitis; Report of the Treatment of a Group of Cases by the Intraspinous Injection of Their Own Blood Serum*—J. Ross Moore, M. D., 520 West Seventh Street, Los Angeles.

   Inadequacy of present methods of treatment; theoretical basis for the employment of the patient's own blood serum intraspinously; classification of cases treated; description of procedure; progress of the cases during treatment; conclusions.
7. *Diffuse Encephalitis*—R. W. Harvey, M. D., Butler Building, San Francisco; Glanville Y. Rusk, M. D., Hooper Foundation, San Francisco.

   A brief clinical record of a case; autopsy and pathological findings; description of slides made from sections of the brain; discussion of the case from the standpoint of diagnosis.

SECOND MEETING

Hall No. 4 (Operating Office), Wednesday, May 17, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *The Genesis and Treatment of Insomnia*—Henry Douglas Eaton, M. D., Pacific Mutual Building, Los Angeles.

   A brief discussion of the common types of insomnia and their causes with particular emphasis on the so-called nervous insomnia; treatment and results based on ten years' experience with such cases.
3. *Post-Traumatic Neuroses; Their Treatment by the Method of Final Settlement and Closure of Litigation Features*—Joseph H. Catton, M. D., 209 Post Street, San Francisco.

   Consideration of "lump sum settlement and closure" of accident cases presenting psychoneurotic pictures. A comparison of this method of handling with "continuing awards" plus psychotherapeutic and other forms of medical treatment.

   Discussion opened by Charles L. Allen, M. D., Investment Building, Los Angeles.

4. *Suicide and Degeneracy*—J. T. Fisher, M. D., 537 S. Virgil Street, Los Angeles.

The lay belief that suicide is generally associated with insanity is not borne out by mental examinations of those who have attempted suicide. Many instances of strong and rational motivating factors. Discussion of the prevalency of suicide in California with presentation of data. Degeneracy will be discussed in relation to the many psychoses and criminal tendencies and to the problem of drug addictions.

5. *Epidemic Encephalitis*—Milton B. Lennon, M. D., Butler Building, San Francisco.

A study of 100 and more cases; frequent difficulty of early diagnosis; remissions in the disease; the very low percentage of recovery; how many ultimately merge into the Parkinsonian group.

Discussion opened by Richard W. Harvey, M. D., Butler Building, San Francisco.

6. *Dry Brain versus Wet Brain*—Cecil E. Reynolds, M. D., Title Insurance Building, Los Angeles.

Signs and symptoms of dry brain and of wet brain; period of apprehension and relative importance of these diphasic variations from normal balance; the application of these surgical lessons to non-operative neurological treatment; examples; posture during operations—(a) above tentorium, (b) below tentorium; posture after operations—(a) above tentorium, (b) below tentorium.

7. *Psychotic Sequelae of Epidemic Encephalitis*—Robert Lewis Richards, M. D., 240 Stockton Street, San Francisco.

Besides the recurrence of Parkinsonian syndromes, paralyses, and sleep disturbances usually noted, I have encountered a number of psychotic sequelae with a relatively recent history of epidemic encephalitis. Epilepsy, varied amnesic states, grades of dementia, psychoneurosis, migraine attacks and ocular disturbances have been noted. In a diagnostic way this is a vital fact particularly with reference to compensation. From a prognostic standpoint the outlook is different. The treatment will naturally be modified on this basis. So far there has been a tendency to associate epidemic encephalitis too exclusively with midbrain and lower orders of nervous structures. Besides the usual transitory toxic involvements of the cortex and meninges in different infections, we have in these cases more permanent and serious changes. Besides the history of the attack, the persisting ocular disturbances are the most reliable indications of this sequence. The personality or make-up of the individual of course plays a role.

GENERAL SURGERY SECTION

CHARLES D. LOCKWOOD, M. D., Chairman,
295 Markham Place, Pasadena.

EDMUND BUTLER, M. D., Secretary,
Butler Building, San Francisco.

FIRST MEETING

Hall No. 2 (Church), Tuesday, May 16, 8 p. m.

1. Chairman's Address and Secretary's Report.
2. *Amputations in the Region of the Knee Joint*—Howard H. Dignan, M. D., 275 Post Street, San Francisco.

Comparison of functional results in the different amputations; description of the Grith-Stokes operation and its modifications; post-operative treatment, physiotherapy, pylons, crutches.

3. *The Hemorrhoid Problem*—Sol Hyman, M. D., Butler Building, San Francisco.

Need for reviewing the subject; changing fashions in operations for piles; untoward results following the various procedures; post-operative complications; the anesthetic; choice of operation according to the criteria; simplicity, effectiveness, comfort, freedom from complications.

4. *Migratory Tumors of the Abdomen*—Asa W. Collins, M. D., 126 Post Street, San Francisco.

Differentiation between migration and metastasis; types of metastatic tumors; types of migratory tumors. Nature of migration; why certain migrate; leiomyomas (fibroids); echinococcus cysts; ovarian cysts. Diagnosis; previous history, clinical symptoms, physical findings; case report.

5. *Amoebic Abscess of the Liver*—Horace J. Brown, M. D., Goldfield, Nevada.

A brief résumé of the etiology, pathology, physical signs and diagnosis; report of a very unusual case; exhibit of X-ray plates taken before operation.

6. *Primary and Secondary Focal Infections in Arthritis Deformans*—Rea Smith, M. D., Merchants National Bank Building, Los Angeles.

We believe that to successfully treat a case of chronic arthritis, persisting after treating the head foci, that a gastrointestinal study both for mobility and motility of the ileocecal coil is essential. If the X-ray demonstrates a right-sided anomaly, that some intestinal operation to restore the function of the large bowel is the first step; that diet and medical treatment to restore the colonic flora to its normal balance is the second step; that orthopedic operation and manipulation on the tendons and joints to restore function is the third step; that joints that have become inflamed on manipulation before the removal of the intestinal focus will stand any rational procedure afterwards without damage.

7. *Tumors of the Breast Arising During Lactation and Pregnancy*—Alson R. Kilgore, M. D., 391 Sutter Street, San Francisco.

Comparative frequency of incidence of the various breast tumors during lactation and at other times. Studies of age of onset and period of pregnancy or lactation as aids in diagnosis. Study of incidence of cancer during pregnancy and lactation by ages of patients—the series studied suggests that as women pass 35 the percentage of incidence of cancer during breast activity rises very sharply. Study of prognosis of tumors, especially cancer, arising during lactation and pregnancy. Prognosis of cancer much more hopeful than usually regarded. Brief comment on treatment of breast tumors during breast activity.

SECOND MEETING

Hall No. 2 (Church), Wednesday, May 17, 2 p. m.

Symposium on Bowel Obstruction.

1. *Indications for and Results of Anchoring the Head of the Colon*—O. O. Witherbee, M. D., Pacific Mutual Building, Los Angeles.

Lowering and distention of head of colon, attended by kinking and angulation, favoring retention of food products, with resulting intoxication; bringing on periodic attacks of excruciating headache of a semi-epileptiform character. Relief secured by straightening and anchoring head of colon.

2. *Further Observations on Colocolostomy in Obstruction at the Splenic Flexure*—Andrew S. Lobingier, M. D., Merritt Building, Los Angeles.
3. *Bowel Obstruction, Diagnosis and Treatment*—Emmet Rixford, M. D., 1795 California Street, San Francisco.
4. *Some Observations on Intestinal Obstruction*—Harold Brunn, 350 Post Street, San Francisco.

General statistics; mortality rate higher than for any other acute abdominal condition; mortality varies with time of operation after onset; statistics gathered from U. C. surgical service. Clinical symptoms and signs; importance of early diagnosis; common erroneous conceptions in acute intestinal obstruction. What constitutes sufficient evidence to warrant immediate operative interference; discussion of experimental data on acute

intestinal obstruction; most acceptable explanation. Whipple's proteose intoxication theory; practical applications in diagnosis and prognosis; possibility of lowering mortality rate by proper use of this experimental data; some operative considerations.

5. *Bowel Obstruction Following Operations Occurring During Convalescing Period*—Alanson Weeks, M. D., 350 Post Street, San Francisco.

Etiology, functional, mechanical; diagnosis; treatment.

6. *Surgical Study of the Periarterial Sympathetic Fibres*—C. Latimer Callander, 516 Sutter Street, San Francisco.

Earlier work on perivascular sympathetic fibres by Jaboulay, Goyet, Potain and Teissier. Histological anatomy of peripheral sympathetic system; course along the arteries and veins in the vascular sheaths; newer aspects of vasomotor equilibrium. Symptoms of vasomotor origin; trophic changes in skin, nails, subcutaneous tissue and muscle; changes in bones and joints; thermic changes; secretory changes; technique of periarterial sympathectomy; post-operative objective reactions; primary vasoconstriction; pathological physiology; secondary reactions; hyperthermia of part distal; pathological physiology; description of recording apparatus; increased peripheral blood pressure; pathological physiology; description of apparatus; dilation of skin capillaries; description of apparatus; pathological physiology. Clinical pictures of possible altered vasomotor balance; traumatic reflex disorders of Babinski-Froment type; causalgia of Weir Mitchell; spontaneous ulcerations; partial or complete ischemic motor paralyses. Analyses of post-operative results in three cases; causalgia; Raynaud's disease; arteriosclerotic gangrene. Questions of future research in peripheral sympathetic system; data on post-operative increase in surface temperature; accurate ocular observations of skin capillary before and after operation; determination of blood pressure changes.

THIRD MEETING

Hall No. 2 (Church), Thursday, May 18, 2 p. m.

1. Election of Section Officers and the Transaction of Other Section Business.

2. *Adenomata of the Thyroid*—John Hunt Shepard, M. D., Growers Bank Building, San Jose.

Terminology and classification of goiter; confusion arising from lax and indiscriminate use of the terms "simple goiter," "colloid goiter," "adolescent goiter," "exopthalmic goiter," "toxic goiter," "nodular goiter" and "adenoma." Life history of adenomata of the thyroid; their probable origin; age incidence of appearance of adenomata; age incidence of appearance of symptoms; occurrence of degenerative changes. Thyroid intoxication from adenomata of the thyroid size of adenoma of little or no consequence; insidious onset; periodic exacerbations; degree of intoxication as measured by the metabolic rate; significance of blood pressure readings; cardiac strain; dangers of iodine therapy; enucleation or subtotal thyroidectomy the rational treatment.

3. *Analysis of Malignant Tumors of the Thyroid*—Clarence G. Toland, M. D., Pacific Mutual Building, Los Angeles.

Analysis made of the thyroid cases that were observed in the St. Vincent's Hospital in my service during the years 1920 and 1921. The observation revealed that malignancy existed in thyroid tumors more frequently than is generally supposed. A number of cases operated for benign tumor proved malignant on microscopic examination, showing the necessity for expert microscopic study of all thyroid tissue. The diagnosis is difficult, but can usually be made by: a careful complete history; physical signs, (a) nodular appearance, (b) firm non-elastic consistency, (c) sudden rapid growth of the tumor; symptoms as pain about head and neck, and loss of weight; several cases operated for malignant tumor proved to be merely a thyroiditis; all cases recur usually within one year. Treatment of malignant thyroid consists in complete removal as soon as diagnosis is made; many cases get into your hands too late for operation, then we resort to X-ray and radium; have seen good results under X-ray treatment in two cases; how long these people will live and be as comfortable as they are now is a question; it is an interesting fact how many cases of malignant thyroid in which the total removal of the thyroid has been done, no definite symptoms of hypothyroidism are produced. This is a strange fact.

4. *Compression of the Lung in Tuberculosis; Medical and Surgical Aspects*—Leo Eloesser, M. D., Butler Building, San Francisco; Philip King Brown, M. D., Medical Building, San Francisco.

Observations on the anatomy and physiology of the collapsed chest; changes in the chest wall, in the collapsed lung, in the mediastinum, in the opposite lung; changes in respiration; clinical observation of patients before operation; indications for operation; operations on the closed chest; on the empyematous chest; points of technique and after-care; case reports; demonstration of slides; results.

Discussion by Chelsey Bush, Arroyo Sanitarium, and Robert Peers, Colfax.

5. *The Diagnosis and Treatment of Surgical Lesions of the Chest*—Charles D. Lockwood, M. D., 295 Markham Place, Pasadena.

Introduction; surgery of the chest has made rapid strides since the war, heretofore considered a field where surgery was seldom justified, it is now almost as accessible as any other region. Factor which brought about this changed attitude; more accurate diagnosis by means of the X-ray and bacteriologic studies; the discovery that the chest cavity may be invaded without resort to cumbersome and complicated apparatus; improved technique. Lesions amenable to surgical interference; abscess of the lung, empyema, tumors, tuberculous cavities. Lantern slide demonstration.

6. *False Diverticulitis of the Sigmoid*—Stanley Stillman, M. D., Stanford Medical School, San Francisco.

Résumé of the pathology; possibility of its being the origin of annular carcinomata; presence of bladder symptoms as an aid in diagnosis; report of six cases.

7. *The Underlying Principles of Plastic Surgery*—J. A. Pettit, M. D., Selling Building, Portland, Oregon.

EYE, EAR, NOSE AND THROAT SECTION

FRANK A. BURTON, M. D., Chairman,
Watts Building, San Diego.

HARVARD MCNAUGHT, M. D., Secretary,
Butler Building, San Francisco.

FIRST MEETING

Hall No. 4 (Operating Office), Monday, May 15, 2 p. m.

1. Chairman's Address and Secretary's Report.

2. *Diphtheritic Otitis Media*—W. J. Mellinger, M. D., San Marcos Building, Santa Barbara.

Introduction;—Tonsillar infection with non-virulent diphtheria bacilli; acute infection of the middle ear with virulent diphtheria bacilli is infrequent; no statement regarding infection of the middle ear with non-virulent diphtheria bacilli; review of literature concerning these types of infection. Observation on eleven patients studied during the past two years, all of which had diph-

theria bacilli in pure culture in the middle ear; only one of these had a virulent diphtheria bacilli infection; method of testing for virulence; character of culture from the nose and throat in these patients; presence of diphtheria in the gums of one of these patients; outcome of treatment of certain of these cases in isolation hospitals; descriptions of treatment and results; conclusions.

Discussion opened by J. David Beatty, M. D., Baker-Detwiler Building, Los Angeles.

3. *Reflex Symptoms in Nasal Accessory Sinusitis*—Robert B. Sweet, M. D., Marine Bank Building, Long Beach.

Pain:—Nature, location, periodicity, obscurity; report of unusual cases.

Discussion opened by Hill Hastings, M. D., Trust and Savings Building, Los Angeles.

4. *Infection of the Petrous Pyramid in Mastoiditis*—Francis M. Shook, M. D., Oakland Bank of Savings Building, Oakland.

General discussion of occurrence of this type of infection; symptomatology of reported cases; pathology and bacteriology of reported cases; association of this infection with meningitis, brain abscess, thrombosis of the venous sinuses of the brain, general infection; report of author's case; demonstration of anatomy of condition; conclusions.

5. *Deafness and Vertigo in Industrial Accident Cases*—Harold Fletcher, M. D., Butler Building, San Francisco.

The importance of early and thorough vestibular tests and physical examinations; the difficulty of determining the industrial responsibility; methods of determining disability; report of cases.

6. *Acute Suppurative Parotitis: Recurrent Attacks*—H. J. Profant, M. D., Cottage Hospital, Santa Barbara.

Rarity of the condition; only a few cases in the literature; recurrent attacks especially rare; etiology; theories; duct infection, hematogenous infection, sympathetic (caeliac or splanchnic), toxin excretion; symptoms; female, age 62, parotid gland involved since childhood; between attacks gland does not evacuate spontaneously; chemical and bacteriological analysis of content; associated vaso-motor disturbances; intermittent rhinitis, bronchial asthma; acute suppurative parotitis with sudden onset, severe pain, stupor and delirium; methods of treatment; probing and catheterization of Steno's duct; conservative and radical procedures considered; expression of duct and gland with good recovery from acute attack; conclusions.

Discussion opened by H. W. Owen, El Centro.

SECOND MEETING

Hall No. 4 (Operating Office), Tuesday, May 16, 2 p. m.

1. Election of Section Officers; Transaction of Other Section Business.

2. *The Tabulation of Functional Hearing Tests*—Simon H. Jesberg, Investment Building, Los Angeles.

Studies of methods used by various American clinics and otologists; lack of uniformity in methods; impossibility of standardizing the various methods; description of the formula method adopted by the International Congress of Otologists; our experience with the method; plea of its adoption.

Discussion opened by I. H. Jones, M. D., 448 Arden Boulevard, Los Angeles.

3. *Sympathetic Ophthalmitis*—Delamere F. Harbridge, M. D., Phoenix, Arizona.

Discussion opened by Roderic O'Connor, M. D., 209 Post Street, San Francisco.

4. *A Plea for More Painstaking Work in Refraction*—L. A. J. La Motte, 5753 Melrose Avenue, Los Angeles.

Opportunity afforded by routine eye examination for detection of general disease; the value of certain steps preliminary to the actual refraction; a study of the relations of accommodation and convergence particularly as found in the presbyop.

Discussion opened by H. H. Walker, M. D., 850 Main Street, Riverside.

5. *Radium in the Treatment of Cataract*—Otis Allen Sharpe, M. D., 516 Sutter Street, San Francisco.

History of radium as a therapeutic agent; review of earliest work with radium and thorium in treatment of cataract; early methods of application of radium for cataract treatment, amount, frequency; work of Cohen and Levin; work and conclusions of Franklin; author's work and conclusion.

6. *The Differential Pupilloscope*—Otto Barkan, M. D., 516 Sutter, San Francisco.

New method for exact numerical determination of pupillary reaction and localization of lesion in the pupillary reflex arc; specially valuable in early diagnosis of tabes and cerebrospinal lues; presentation of instrument and résumé of application in ophthalmology with report of cases.

UROLOGY SECTION

George W. Hartman, M. D., Chairman,
999 Sutter Street, San Francisco.

Louis Clive Jacobs, M. D., Secretary,
Flood Building, San Francisco.

FIRST MEETING

Hall No. 5 (Auditor's Office), Monday, May 15, 2 p. m.

1. Chairman's Address and Secretary's Report.

2. *Diagnosis of Gonorrhea*—George W. Hartman, M. D., 999 Sutter Street, San Francisco.

Usual criteria for diagnosis; variations in gram staining; experiments in artificial propagation of the gonococcus; complement fixation.

3. *Diagnosis and Surgical Treatment of Tumors of the Kidney*—William E. Stevens, M. D., 210 Post Street, San Francisco.

Report of cases of carcinoma hypernephroma and papillomatous epithelioma of the kidney pelvis. Lantern slides illustrating the value of pyelography in the diagnosis of renal tumors.

Discussion opened by Louis C. Jacobs, M. D., Flood Building, San Francisco.

4. *Grave Renal Haematuria Due to Degenerative Changes in the Blood Vessels of the Papillae and the Pyramids, with a Report of a Case Requiring Nephrectomy*—Granville MacGowan, M. D., Brack Shops Building, Los Angeles.

Résumé of the anatomy of the renal papilla; pathological consideration of the haematuria due to: (a) varix of the papilla, (b) angiomas of the papillae, (c) tuberculosis of the papilla, (d) calculus incrustations of the papilla, and (e) cancer of the papillae. Differential diagnosis and its difficulties; no medical therapeutics. Surgical intervention when required; what to do; its chance of success.

Discussion opened by Frank Hinman, M. D., 516 Sutter Street, San Francisco.

5. *A Case of Bilateral Pyelitis Due to the Bacillus Pyocyaneus*—Chas. P. Mathe, M. D., Phelan Building, San Francisco.

An unusual kidney infection diagnosed through ureteral catheterization; case report; pathogenesis of B. Pysocyaneus in the genito-urinary tract; rarity of occurrence; a brief review of the literature; treatment and results.

6. *The Effect Upon the Kidney Following Ligation of the Ureter*—Anders Peterson, M. D., Brockman Building, Los Angeles.

A brief review of the experimental and clinical work where the effect upon the kidney has been studied following ureteral ligation; illustrations of specimens obtained from animals after various periods of time have elapsed between the time of ligation and the removal of the specimen; report of the results in 12 cases where the ureter was ligated in surgical procedures.

Discussion opened by Leon J. Roth, 512 S. Oxford Avenue, Los Angeles.

7. *Anatomical Studies of the Kidney*—Frank Hinman, M. D.; A. E. Belt, M. D.; B. M. M. Morrison, M. D.; R. K. Lee-Brown, M. D., 516 Sutter Street, San Francisco.

Renal anatomy as understood and taught in the ordinary text-book; methods of present study; injection and digestion; injection and stereopticon X-ray pictures; specimens rendered transparent by digestion of fat. Comparative anatomical studies; demonstration of specimen and lantern slides. Discussion and summary.

SECOND MEETING

Hall No. 5 (Auditor's Office), Tuesday, May 16, 8 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Pre-Cancerous and Early Cancerous Lesions of the Genito-Urinary Tract*—J. R. Dillon, M. D., 516 Sutter Street, San Francisco.

Description and pathology of lesions of potential malignancy appearing in the genito-urinary tract; earliest signs and symptoms; diagnosis; prognosis; general statistics.

3. *Radium Treatment in Carcinoma of the Prostate*—R. L. Rigdon, M. D., 291 Geary Street, San Francisco.

Relative frequency of carcinoma as seen in 300 cases of enlarged prostate, observed at the Lane-Stanford Hospital; results of surgical treatments; results of surgery and of radium; technique of radium applications; dosage; case reports.

4. *Two Hundred and Twenty-three Consecutive Prostatectomies—Suprapubic and Perineal*—Robert V. Day, M. D., Baker-Detwiler Building, Los Angeles.

Functional results; structural results; mortality rate; subsequent state of general health; precautions requisite to obtain best results; dangers incident to operation and drainage.

Discussion opened by Herbert A. Rosenkranz, M. D., Story Building, Los Angeles.

5. *Is Syphilis Curable and May It Eventually Be Abolished?*—Victor G. Vecki, M. D., 516 Sutter Street, San Francisco.

The standpoint is taken that syphilis is a comparatively easily curable disease, and that by the use of improved methods of blood examinations and the so-called rhythmic treatment, and with the proper help of national, State and city governments, the scourge could be abolished.

6. *Studies in Ureteral Catheterization—Preliminary Report*—Henry A. R. Kreutzmann, M. D., 323 Geary Street, San Francisco.

Technic is to insert catheters for varying distances in both ureters and determine the amount of phenolsulphonephthalein obtained after intravenous injection from each catheter and from leakage into the bladder over a period of half an hour. The presence of pain, anuria and haemorrhage at the various levels is also determined.

Discussion opened by Lionel P. Player, M. D., 516 Sutter Street, San Francisco.

7. *An Anatomical and Embryological Study of the Perineum—Lantern Slides*—W. B. Wesson, M. D., Flood Building, San Francisco.

The material used consisted of 31 human embryos and dissections of fresh cadavers; the boundaries of the recto-urethralis muscle were determined and the reason for its value as a landmark in the perineal prostatectomy operation was ascertained; the development of the peritoneum of the pelvis was followed with particular reference to any part it might play in the formation of Denonvilliers fascia.

Discussion opened by Frank Hinman, M. D., 516 Sutter Street, San Francisco.

8. Urological Demonstrations—

(a) *A new apparatus for holding the Cystoscope during ureteral catheterization*—Louis Clive Jacobs, Flood Building, San Francisco.

(b) *Anatomical studies of the kidney*—Frank Hinman, M. D.; Elmer E. Belt, M. D.; Duncan M. Morrison, M. D.; R. K. Lee-Brown, M. D., 516 Sutter Street, San Francisco.

ORTHOPEDIC SURGERY SECTION

W. W. Richardson, M. D., Chairman,
Brockman Building, Los Angeles.
G. J. McChesney, M. D., Secretary,
Flood Building, San Francisco.

FIRST MEETING

Hall No. 5 (Auditor's Office), Tuesday, May 16, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *Old Bilateral Dislocation of the Patella*—Henry A. Ryfkogel, M. D., 516 Sutter Street, San Francisco.

Report of case with former unsuccessful operation on one side and successful operation on other side by the writer, with discussion of methods.

3. *Congenital Elevation of the Shoulders with Operation for Cure*—Arthur L. Fisher, M. D., Medical Building, San Francisco.

Frequency of condition; description of condition with symptoms and disability; causes; description of new operation for cure; result.

4. *Repair of Tendons in the Fingers*—Sterling Bunnell, M. D., 516 Sutter Street, San Francisco.

Atraumatic technique; essential; gliding mechanism; method of repair; free tendon graft; indication and contra-indication; after-treatment.

5. *The Treatment of Painful Affections Involving the Cervical Vertebrae*—H. L. Langnecker, M. D., Lane Hospital, San Francisco.

Group types; frequency of cases without bone pathology; predisposing causes, such as postural defects or occupational strains; the value of various methods of treatment, including rest; elimination of infectious foci; partial fixation; avoidance of strain; correction of defective posture; change of occupation; improvement of muscle tone; importance of active exercises.

SECOND MEETING

Hall No. 5 (Auditor's Office), Wednesday, May 17, 8 p. m.

1. Election of Section Officers and the Transaction of Other Section Business.
2. *Spastic Paraplegia—Moving Pictures of Two or More Cases Treated in Different Ways*—James T. Watkins, M. D., Medical Building, San Francisco.

Presentation of the orthopedic problem of Little's spastic paraplegia; avoids consideration of monoplegias and hemiplegias; there seems to be general agreement about the neural pathology; there is considerable consistent clinical evidence as to the cause; there is no disagreement as to the objective symptomatology; there is no disagreement as to the conservative orthopedic treatment to be followed, but there is radical divergence of opinion as to surgical courses of treatment to be followed. A comparison will be made of the reports of immediate brilliant results which at later examination proved to be disappointing; between forty and fifty cases are being traced throughout California. If they can be located in time their results will be reported; in the end an attempt will be made to interpret these conflicting data.

3. *The Modern Treatment of the Weak and Flat Foot*—George J. McChesney, M. D., Flood Building, San Francisco.
   Definitions; résumé of pathology and symptoms; old methods of treatment; fallacies; newer methods.
4. *Brisement Forces and the Pre- and After-Treatment*—A. Gottlieb, M. D., Consolidated Realty Building, Los Angeles.
   Forcible manipulation of joints with inhibited motion on account of various contractures has been practiced for many years past. It has fallen into disrepute because the results have not been gratifying and frequently mishaps have occurred. Failures should be attributed to the following factors which are discussed in this paper; these are: 1. Lack of pre-operative treatment; 2. disregard of contra-indications; 3, incorrect technic of the manipulation; 4. neglect of or inadequate after-treatment.
5. *Re-education of Crippled Children*—Charles G. Stivers, M. D., Auditorium Building, Los Angeles.
6. *Congenital Deformities*—Harry L. Schurmeir, M. D., San Marcos Building, Santa Barbara.

ANAESTHESIOLOGY SECTION

Mary E. Botsford, M. D., Chairman,
807 Francisco Street, San Francisco.

Eleanor Seymour, M. D., Secretary,
1329 So. Grand Avenue, Los Angeles.

MEETING

Hall No. 6 (Sentinel Dining Room), Monday, May 15, 8 p. m.

1. Chairman's Address and Secretary's Report.
2. *Post-Tonsillectomy Pulmonary Abscesses*—Mary E. Botsford, M. D., 807 Francisco Street, San Francisco.
   Incidence; diversity of opinion as to etiology; role of motor-driven anaesthetic appliances; comparative effects of general and local anaesthesia; light versus deep anaesthesia; danger of abolishing laryngeal reflexes; deductions from statistics.
3. *The Relation of Surgeon and Anaesthetist*—Saxton T. Pope, M. D., Butler Building, San Francisco.
   Dependence of the surgeon upon anaesthetist; obligations of surgeon to anaesthetist; co-ordination between stages of anaesthesia and stages of surgical procedure; what the surgeon can expect from the anaesthetist and what he cannot expect; surgical trespass over the bounds of anaesthesia.
4. *Organization of Hospital Anaesthesiology Department*—Caroline B. Palmer, M. D., 2401 Sacramento Street, San Francisco.
   Personnel; assignment of work; compensation; care of apparatus; supplies; anaesthetist's examination of patients before anaesthesia and choice of anaesthetic; anaesthetist's part in care of patients before, during and after anaesthesia; obstetrical anaesthesia and analgesia; instruction of students and training of anaesthetists; anaesthetic records and reports; résumé of department of anaesthesiology at Lane and Stanford University Hospitals for past fifteen years.
5. *Analysis of Anaesthetics Given in Eighty Consecutive Brain Operations at the University of California Hospital*—Dorothy A. Wood, M. D., University Hospital, San Francisco.
   Technique of administration; blood pressure findings in two types of cases: (a) cases showing marked increase in intracranial pressure, (b) cases showing slight increase in intracranial pressure; conclusions.
6. *The Clinical Uses of Oxygen*—Lorruli A. Rethwilm, M. D., 2215 Webster Street, San Francisco.
   Historical; increased use of late; oxygen in various anoxemias; oxygen with anaesthetics: (a) surgical, (b) obstetrical; observed benefits in our routine use of it.

Pacific Coast Association of Anesthetists

Joint meeting with the Section on Anesthesiology of the California State Medical Society.

George P. Waller, M. D., President,
Los Angeles.

Mary E. Botsford, M. D., Vice-President,
San Francisco.

Eleanor Seymour, M. D., Secretary-Treasurer,
Los Angeles.

Frank H. McMechan, Honorary Secretary,
Avon Lake, Ohio.

Walter R. Crane, M. D., Los Angeles.
Caroline B. Palmer, M. D., San Francisco.
Robert L. Charles, M. D., Denver, Colo.
Louis H. Maxson, Seattle, Wash.
Louise A. Oldenbourg, M. D., Oakland, Cal.
David E. Hoag, M. D., Pueblo, Colo.

FIRST MEETING

Hall No. 6 (Sentinel Dining Room), Tuesday Afternoon, May 16, 2 p. m.

1. *Spasticity from Inflammation in Relation to Anesthesia* (President's address, Pacific Coast Association of Anesthetists)—George P. Waller, M. D., Los Angeles.
2. *Time As An Element in Anesthesia in Children*—Mary T. Murphy, M. D., San Francisco.
3. *Anesthesia and Its Relation to the Patient, from a Surgeon's Standpoint; Type of Anesthesia and Its Relation to Existing Pathology; Emoluments to the Anesthetist*—Harlan Shoemaker, M. D., Los Angeles.
4. *Suggestive Leads in Anesthesia*—Frank H. McMechan, M. D., Avon Lake, Ohio.
5. *Sacral Anesthesia; A New Method of Administration with Report of Use in 400 Urologic and Gynecologic Cases*—Albert J. Scholl, Jr., Mayo Clinic, Rochester, Minn.

EXECUTIVE SESSION

If you have anything of constructive value to propose for the welfare of the specialty or of its associations, do not hesitate to present it at this session.

SECOND MEETING

Hall No. 6 (Sentinel Dining Room), Tuesday Evening, May 16, 8 p. m.

1. *Ethyl Chloride as a General Anesthetic*—Louise A. Oldenbourg, M. D., Oakland, Cal.
2. *Anesthol, a Most Useful Anesthetic Mixture*—Louis H. Maxson, M. D., President of the Society of Anesthetists, Seattle, Wash.
3. *The Physiological Effects of Nitrous Oxide*—Neil C. Trew, M. D., Los Angeles.
4. *Nitrous Oxide Oxygen Anesthesia in Infants*—Mary E. Botsford, M. D., San Francisco.
5. *Symposium on Intratracheal Anesthesia*—Mary Kavanagh, M. D., San Francisco; Edith Williams, M. D., San Francisco.

OBSTETRICS AND GYNECOLOGY SECTION

Harry M. Voorhees, M. D., Chairman,
Brockman Building, Los Angeles.

L. A. Emge, M. D., Secretary,
Stanford University Hospital, San Francisco.

FIRST MEETING

Hall No. 3 (General Store), Monday, May 15, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *Infection of the Placenta*—J. Morris Slemons, M. D., Pacific Mutual Building, Los Angeles.
   Bacterial infection of the placenta usually depends upon premature rupture of the membranes. The consequent diminution in the capacity of the uterine cavity with retraction of the uterine muscle disturbs the nutrition of the amniotic epithelium.

In this way its resistance to bacterial invasion is lessened. Through this portal organisms may gain entrance to the maternal circulation, a fact which explains the presence of fever during parturition. Even more frequently the fetal circulation is invaded. The resulting pathological lesions may be limited to a mild degree of inflammation of the umbilical cord, or at the other extreme, the fetus may suffer a general septicaemia, causing its death during labor or within a few days after birth. The prevention of placental infection merits consideration in determining the technique to be employed in the conduct of labor.

Discussion opened by Frank Lynch, M. D., University California Hospital, San Francisco.

3. *Cardiac Decompensation in Pregnancy and Labor*—Karl L. Schaupp, M. D., 516 Sutter Street, San Francisco.

Cardiac disease an individual problem with each patient during pregnancy and labor; the types of cardiac lesions met with in pregnancy and the resultant symptoms; the necessity of close supervision to forecast the probable effect of labor on the cardiac pathology; when does cardiac pathology require interference with pregnancy? Brief summary of clinical observations; conclusions.

Discussion opened by Armstrong Taylor, M. D., Butler Building, San Francisco.

4. *The Intermediate Cervical Repair Following Confinement*—Titian J. Coffey, M. D., Marsh-Strong Building, Los Angeles.

Introduction; causative factors; diagnostic points in cervical haemorrhage; character of cervical laceration; condition of cervix immediately following birth; condition of cervix on ninth day; technique of operation; advantages of operation; results six weeks following operation; conclusions.

Discussion opened by Alfred B. Spalding, M. D., Lane Hospital, San Francisco.

5. *A Biological Test for Pregnancy*—Merrill W. Hollingsworth, M. D., Anaheim.

Remarks on need of an easily applied biological test for pregnancy; is the slight glycosuria in early months of pregnancy renal or is it a true glycochemia? Work of Miss Grunthal; work and report of Kammitzer and Joseph; difficulties encountered in applying this test on our cases; slight modification made by us; presentation of statistics; summary.

Discussion opened by John Vruwink, M. D., Pacific Mutual Building, Los Angeles.

SECOND MEETING

Hall No. 3 (General Store), Tuesday, May 16, 2 p. m.

1. *Clinical Mistakes in Gynecological Diagnosis*—Roland E. Skeel, M. D., Title Insurance Building, Los Angeles.

Anatomical and pathological diagnosis more simple in diseases of the female pelvic organs than other diseases of the abdomino-pelvic viscera; imperfect examination or inadequate knowledge the reason for most gross errors in this class; gynecological disease classified for clinical purposes into: (1) those imperatively demanding interference, (2) those in which observation is desirable, (3) those whose effect upon the general health and the production of symptoms is likely to be unknown in the individual patient. Plea for a more conservative attitude towards the third class.

Discussion opened by Albert V. Pettit, M. D., Lane Hospital, San Francisco.

2. *Posterior Vaginal Drainage with Description of New Instrument Used as a Vaginal Pelvic Guide*—Frank R. Girard, M. D., Flood Building, San Francisco.

Treatment of acute pelvic inflammatory disease; indications for non-operative and operative treatment; choice of time for operation; indications for drainage; vaginal versus abdominal drainage; mechanics of pelvic drainage; choice of drainage material; description of new instrument to facilitate vaginal drainage.

Discussion opened by J. Craig Neel, 516 Sutter Street, San Francisco.

3. *Results of Five Years' Use of Radium in Gynecology*—Alice F. Maxwell, M. D., University Hospital, San Francisco.

Type of cases treated; method of application; results of treatment; comparison with results of surgery.

Discussion opened by Frank C. Ainley, M. D., Brockman Building, Los Angeles.

4. *Uterine Myomata and Their Treatment*—William H. Gilbert, M. D., Brockman Building, Los Angeles.

Prevalence of uterine myomata in middle-aged single women who have not borne children; fibroids and pregnancy; influence on conception, as cause of sterility, as cause of miscarriage and abortions; relationship of myomata to successful delivery of the pregnant woman. Degenerative changes; non-malignant, malignant changes in tumor, malignancy as complication. Treatment: radiation, its indications and range of usefulness, impossibility of preservation of sex glands. Surgical importance of early removal; all myomatous growths cause trouble in later life; surgical treatment given preference; preservation of sex glands possible by surgery; surgical procedure.

Discussion opened by Ludwig A. Emge, M. D., Stanford Hospital, San Francisco.

5. *Rational Glandular Therapy in Gynecology*—Arthur Lee Munger, M. D., Medical Building, San Francisco.

Endocrine therapy in general is an empirical procedure because the commercial products used are so extremely variable; the thyroid; the respective importance of its iodine versus its arsenic content; the ovary: a discussion of the commercial products and a theoretical explanation of the varying results in ovarian therapy; the pituitary body: the importance of the gland in the sex complex and the failure of the pituitary therapy; the question of uni- and poly-glandular therapy; the treatment of menstrual disturbances by glandular therapy remains the outstanding problem; glandular therapy and menopause; glandular therapy and infantilism.

Discussion opened by Frederick M. Loomis, M. D., 350 Twenty-ninth Street, Oakland.

THIRD MEETING

Hall No. 3 (General Store), Wednesday, May 17, 8 p. m.

1. Election of Section Officers and the Transaction of Other Section Business.

2. *The Technique and Organization of the Los Angeles Maternity Service*—Lyle G. McNeile, M. D., Pacific Mutual Building, Los Angeles.

General organization and object of the maternity service; maternity dispensary for pre-natal and post-partum care; method of keeping records; method of handling internes and students; technique of preparation of the room; preparation of the patient; examination; external, vaginal, rectal; treatment during labor; post-partum care; follow-up work; nursing care; end results.

3. *Pre-Natal Care in Private Practice Based on Last One Hundred Consecutive Cases*—Adelaide Brown, M. D., 909 Hyde Street, San Francisco.

Physical examination; pelvic measurements; routine Wassermann; hygiene of pregnancy; pre-natal visit; weight; blood pressure; urine examination; preparations for confinement; preparation for baby's care; pre-obstetrical examination at 7-7½ months; presentation and position; instruction about labor, child's routine, maternal nursing.

Discussion opened by J. Morris Slemons, M. D., Pacific Mutual Building, Los Angeles.

4. *Post-Natal Care*—Louis I. Breitstein, M. D., 350 Post Street, San Francisco.

The post natal period, a link in the chain of preventive medicine; the essential features of pre-natal and intra natal care so necessary for the success of post-natal care; puerperium with the routine care of mother and the new-born; follow-up system; the post-natal nurse; the importance of post-natal examinations.

Disenssion opened by Andrew J. Thornton, M. D., Timken Building, San Diego.

5. *The Treatment of Hyperemesis Gravidarum*—G. Carl H. McPheeters, M. D., Mattei Building, Fresno.

The purpose of this paper is to call attention to the common occurrence of various types of vomiting of pregnancy; it will concern itself mainly with mild or ambulatory and the severe or toxic types; it will take up the principle of treatment such as elimination, diet and medicines used; it will touch on the question of focal infection; in the severe type it will bring up also the question of interference with pregnancy as well as care after recovery; in the main, the paper is an earnest appeal for a more detailed attention to this common and often serious complication of pregnancy and gives a broad outline of the methods of treatment.

Discussion opened by Newell H. Bullock, Twohy Building, San Jose.

STATE MEDICAL SOCIETY MEETINGS

Year	Presidents	Place of Meetings
1856	E. F. Keene	Sacramento
1857	H. Gibbons	Sacramento
1858	A. B. Stout	San Francisco

FARES AND SERVICE FROM POINTS IN CALIFORNIA TO YOSEMITE VALLEY MEETING OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA, MAY 15 TO 18, 1922.

From San Francisco to Yosemite Valley and return.$19.50
From Oakland to Yosemite Valley and return..... 19.50
From Los Angeles to Yosemite Valley and return... 27.00

Good for 15 days from date of sale.

From San Francisco the train service will be as follows:

Santa Fe No. 2	Santa Fe No. 42	Santa Fe No. 22	S. P. No. 2	S. P. No. 24	S. P. Nos. 38-50	S. P. Nos. 84-90	Leave
8:00 p	4:00 p	9:00 a	11:00 p		4:00 p	8:40 a	San Francisco
1:26 a	8:50 p	1:50 p	4:50 a	8:30 p	9:18 p	1:15 p	Ar. Merced
	8:15 a	1:50 p		8:15 a		1:50 p	Lv. Merced
	11:55 a	5:55 p		11:55 a		5:55 p	Ar. El Portal
	12:00 p	6:05 p		12:00 m		6:05 p	Lv. El Portal
	1:15 p	7:15 p		1:15 p		7:15 p	Ar. Yos. Valley

From Los Angeles the train service will be as follows:

S. P. No. 9	S. P. Nos. 81-109	S. P. No. 109	S. P. No. 49	Leave
		10:00 pm	7:50 pm	Los Angeles
		12:40 pm	7:50 am	Ar. Merced
		1:50 pm	8:15 am	Lv. Merced
		5:55 pm	11:55 am	Ar. El Portal
		6:05 pm	12:00 m	Lv. El Portal
		7:15 pm	1:15 pm	Ar. Yos. Valley

The S. P. R. R. Co. and the A. T. & S. F. R. R. Co. will operate sleeping cars as follows:

S. P. Train No. 86, leaving San Francisco Ferry Station at 11:00 p. m. Car will be ready for occupancy at Oakland Pier after 9:00 p. m. and will be detached from train at Merced on arrival, so that occupants will not be obliged to vacate until just time enough to get their breakfast and depart from Merced on Yosemite Valley train at 8:00 a. m.

The A. T. & S. F. R. R. Co. will operate sleeping car service on their Train No. 2, leaving San Francisco Ferry Station at 8:00 p. m. These cars will also be detached from train at Merced and the passengers can occupy same until time to leave in the morning.

From Los Angeles the S. P. Company will operate sleeping cars on their Train No. 49, leaving Los Angeles at 7:50 p. m. and arriving at Merced at 7:50 a. m. and connecting with Yosemite Valley Railroad train to El Portal and Yosemite Valley.

The sleeping car fares will be as follows:

San Francisco to Merced—lower berth.....$3.00
Los Angeles to Merced—lower berth..... 3.75

Reservations for berth, compartment or drawing-room in sleeping cars should be made to the nearest agent of the railroad over which you desire to travel. Railroad tickets should also be purchased from those agents, who will be in position to give any additional information in regard to train service.

All drivers of Yosemite Transportation System automobiles will be instructed to assist doctors coming into the Valley in automobiles in every way. If they are having trouble of any kind and a Y. T. S. automobile is coming along, the driver will do everything he can to assist them in every way and, if not possible to repair automobile so that journey can be resumed, will carry word to the next telephone station and arrange for necessary help.

Plenty of oil and gasoline should be taken before leaving main highway, as service stations are few and far between. Water, of course, is available most any place.

1922 MEMBERSHIP IN THE STATE SOCIETY

If your 1922 membership dues are unpaid, this is the last issue of the Journal you will receive until you have again been restored to good standing.

STATE SOCIETY

PROCEEDINGS OF THE SECOND ANNUAL CONFERENCE BETWEEN THE COUNCIL OF THE STATE SOCIETY AND OFFICERS OF CONSTITUENT SOCIETIES

This conference was held in San Francisco on September 24, 1921. There will be two similar conferences held during the state convention in Yosemite May 15 to 18 as shown elsewhere in this issue of the Journal. The resolutions endorsed and passed for two similar conferences are here reprinted from the Journal of November, 1921, as a basis for consideration of further meetings.

1. **Monthly Report of County Secretaries:**
RESOLVED, That the Council of the State Medical Society and the officers of constituent societies meeting in joint session unanimously endorse and approve the program of monthly reports by secretaries of constituent societies to the State Society. It is to the best interest of medicine for the public and the profession that these reports be forwarded every month and made as complete as possible, regardless of whether the society holds a meeting or not.

2. **Constituent Society Representation at the State Meeting:**
RESOLVED, (a) That the Council of the State Medical Society and the officers of constituent societies, meeting in joint session, unanimously endorse and approve the policy of the State Society's including in the program of annual meetings arrangements for one or two joint meetings between the council and the officers of constituent societies as part of the official program. It is understood that this will necessitate the presence at each State meeting of the officers of each constituent society in an official capacity;
(b) That care be used in the selection of delegates and alternates of constituent societies to the State meetings, so that the House of Delegates may be truly representative; and that it be interpreted as a most important public duty for the delegates and alternates to attend the State meetings; and
(c) That, whenever the officially elected delegates and alternates fail to attend the State meeting for any legitimate reason, the president or secretary of the society, who will be present in another official capacity, may act as delegate.

3. **Change of Officers:**
RESOLVED, (a) That this joint meeting go on record as unanimously in favor of a policy that will insure, as far as may be, a fair degree of permanency in the secretary's office of constituent societies. To this end, it is our opinion and our recommendation that constituent societies select their secretaries with the greatest care and that frequent changes in this office be avoided.
(b) In order further to secure consecutive policy in the constituent societies, we recommend that all constituent societies elect in addition to the secretary an assistant secretary, who shall be an understudy to the secretary and who for any legitimate reason shall assume the duties of secretary.

4. **Training of Officers for Medical Organization Purposes:**
(a) This body unanimously recommends that the State Society prepare an adequate outline of the duties of president, vice-president and secretary-treasurer of constituent societies, and that the state secretary be requested to present this program at the next meeting of this joint body for consideration.
(b) In order that officers of the State and constituent soiceties may serve their purpose in the most useful way, we recommend that it be part of the official duty of officers of constituent societies when in San Francisco to visit the state offices for the discussion of special problems peculiar to our organization.

5. **Stated Meetings of the State and Constituent Society Officers:**
RESOLVED, That this body unanimously endorses and approves the policy of definite meetings of state and constitutent society officers as follows: One or two meetings at and during the annual meeting and one midyear meeting, to be held alternate years in Los Angeles and San Francisco.

6. **Program Arrangements for Constituent Societies.**
RESOLVED (a) That each constituent society prepare and execute each year one special program; that this program be sent to the state secretary, who will give it publicity, with the hope that it will be taken in toto as the program of another society;
(b) That the program committee of the State Society be requested to prepare and issue to all societies one or more uniform programs, to be discussed at the same monthly meeting by every society in the state. These programs should relate to subjects of importance to all members of the profession;
(c) That it be understood to be a duty of the councilor for each councilor district to visit at least one meeting a year of each constituent society within his district; and that he, in the discharge of this duty, should arrange with the secretary of the society to be visited for the program for that particular meeting; provided, that each councilor report on the execution of this part of the program at the state meeting;
(d) That the policy of a certain number of open meetings for each constituent society is approved and recommended. In the opinion of this body each constituent society should hold not less than one nor more than three open meetings a year, to which the general public shall be invited and which may or may not include speakers not medical men. In our opinion programs of this character should have the approval of the state program committee before being given;
(e) That the county program committee should seriously consider, at least in small counties, variations in the location of the meeting place, using different towns in the county for different meetings, and often in smaller places holding the meetings at the residences of individual members;
(f) Joint meeting of more than one society. This body approves as good policy an occasional joint meeting between small groups of constituent societies suitably located for this purpose. Programs at these meetings may be held either by one society, with the other societies as guests, or arrangements may be made for a combined program in which each of the societies of the group shall be interested;
(g) That the program committee of the State Society, under the chairmanship of the secretary, be used as a clearing house for all program work of constituent societies throughout the state; that it be interpreted to be a duty of the state and local secretaries to confer by correspondence or otherwise in making plans for advance programs; and that each constituent society have a list of programs as far as possible in advance of the meetings.

7. **Extension Work of the State Society:**
RESOLVED, That this body endorses and approves the idea of the State Society's developing and maintaining an extension program that will provide a list of available subjects and speakers, from which local program committees may select and extend invitations as they desire.
RESOLVED, That we urge and recommend that this extension program be expanded to include clinics, lectures, research work, etc., in the larger centers this program to be arranged in short all-day courses of from one to four weeks each, beginning and ending upon definite dates.

8. **County Editors:**
RESOLVED, That this body recommend to the Council: that the present system of county associate editors for the State Journal be discontinued, and that instead the secretary of each constituent society ex-officio act as editor for his county or district.

REPORT OF THE BOARD OF MEDICAL EXAMINERS

The Board of Medical Examiners of the State of California held a regular meeting in Los Angeles February 13 to 16.

Some seventy-seven applicants appeared for the written examination, of which approximately seventeen holders of drugless practitioners' certificates qualified for the six subject advanced examination for a physician and surgeons' certificate. Eleven graduates of various drugless and chiropractic schools, including the Western School of Chiropractic, California School of Chiropractic, National School of Chiropractic and Los Angeles School of Chiropractic, wrote the examination for a drugless practitioner's certificate and twelve Japanese midwives wrote the examination for a certificate to practice midwifery.

The board endeavored to bring this examination to the attention of those graduates of chiropractic schools now practicing in California in violation of the law, hoping that a larger number than wrote the examination would be able to fulfill the statutory requirements for admission to examination, i. e.:

1. A California high school education or its equivalent.

2. Two thousand hours' education in subjects specified in the Medical Practice Act covering a period of two terms of thirty-two weeks each.

3. A diploma from a legally chartered teaching institution, giving the required course of instruction.

4. Satisfactory evidence of good moral character.

The chiropractic organization promoting the publicity for the initiative, which will appear on the ballot at the next November election, whereunder it is proposed to create a separate chiropractic board with provisions for the wholesale licensing of those now practicing chiropractic in California, waged an active campaign to intimidate the qualified chiropractors so that they would be fearful of filing an application with the Board of Medical Examiners.

A considerable number of physicians and surgeons licensed in other States qualified for direct reciprocity certificates, while some thirty-five or more successfully passed the oral examination, as required under Section 13, of those who base their application on a certificate issued by some other state prior to August 1, 1901. Reciprocity certificates were also issued to a number of graduates of osteopathic schools who presented a license issued by some other state or territory of the United States, fulfilling the statutory requirement under Section 13.

Eight of those licensed to practice osteopathy in the State of California availed themselves of the opportunity offered under Secton 12½ of the Medical Act. All successfully passed the oral examination required thereunder and will be issued a physician and surgeon certificate.

The usual number of legal hearings were held and resulted in the revocation of the licenses of Jacob L. Arbogast,* M. D., Sacramento, and Lawrence S. Bartlett, M. D., San Francisco, both charged with violation of the State Narcotic Act; Charles E. Marsh (Naturopath), San Diego, and Frederick N. Staples, M. D., Los Angeles, both charged with performing an illegal operation; Holmes F. Troutman, M. D., Oakland, now incarcerated in San Quentin Prison, had his license revoked on the record of his conviction for a crime involving moral turpitude. The license of Charles E. Brown, M. D., Fresno, was suspended for a period of one year on a charge of violation of the State Narcotic Act. The board restored the license of Robert Allen Woods, D. O., which was revoked at the February (1921) meeting on a charge of violation of the ninth subdivision of Section 12.

Those licentiates who plead guilty to a charge of violation of the State Pharmacy Act in connection with dispensing or selling narcotics often claim they have no knowledge that such a plea establishes grounds for the revocation of their license issued by the Board of Medical Examiners, hence it is advisable to give this fact as wide publicity as possible.

The results of the written examination show the following applicants passed the examination:

1—For Physician's and Surgeon's Certificate—Elizabeth Blake, Georgia M. Clark, George H. Cook, Curtis E. Decker, Robert J. Dixon, Frederick D. Facey, Thomas R. Haig, James M. Huston, Joseph Jelinek, Winifred W. Jenney, Harry M. Kanner, Benjamin Katz, George M. Landrock, Mary L. LeClere, Ernest G. Motley, Gerald K. Nider, B. C. N. O'Reilly, Evangelin N. Percival, Abilio G. Das. Reis, Herman F. Rey, John M. Schmoele, B. V. Scott, Kenneth E. Smiley, Edwin C. Sorensen, Wm. McLean Thomas, Bion S. Warner, Leonard Woods.

2—For Drugless Practitioner's Certificate—Hannah L. Cater, Rowland H. Frazier, Alfred Harlow, Myrtle S. Johnson, Simon L. Nord, Joseph A. Sanford.

3—Certificates were also granted applicants on Government credentials (Section 12) as follows: Royal R. Baronides, James D. Bobbitt, Harvey R. McAllister.

The next regular meeting will be held in Native Sons' Hall, San Francisco, June 26 to 29, 1922, with the annual meeting scheduled at the State capitol, Sacramento, October 16 to 19, 1922.

The annual report of the Secretary-Treasurer covering the various activities of the board for the year 1921 will be published in the forthcoming issue of the Directory of those licensed under the Medical Practice Act of the State of California.

* Revocation set aside at April, 1922, meeting pending rehearing at June, 1922, meeting.

COUNTY SOCIETIES

Alameda County Medical Association (reported by C. L. McVey, secretary)—The March meeting was held March 20 at the Public Health Center. Rabbi Coffey addressed the meeting regarding the revision of the "Marriage Law" in the state of California. Rabbi Coffey's remarks were discussed by the members and suggestions were made that the society consider the advisability of endorsing the proposed changes in the law.

Henry Petray addressed the meeting in regard to a new physicians' and dentists' office building to be located in Oakland.

Rothganger presented a case of fracture of the leg, complicated with a brachial plexus, palsy or Klumpke paralysis.

Hayward Thomas read a paper on the new surgical treatment of acute mastoiditis. He also considered the question of removal of tonsils and adenoids during the period of acute inflammation.

Nutting read a report of the eye findings in fifty consecutive cases of influenza.

McNaught read a paper on the relations of laryngology, rhinology and otology to general medicine.

S. F. Worswick spoke upon the methods used in the manufacture of clinical thermometers.

Fresno County Medical Society (reported by Thomas F. Madden, secretary)—The evening of March 25 was spent with the State Secretary as our guest, and those members who were absent will never know how much they missed. By all of those present it was voted the most instructive meeting we have ever attended. More of such gatherings are sure to follow and the Council of the State Society is to be highly commended for instituting this character of extension work.

The regular April meeting was held in the Commercial Club on April 4 with the following members present: G. W. Walker, McKinney, Robinson, Ransom, Steinwand, Brown, Miller, Stein, Vanderburgh, Pettis, Aller, McConnell, J. R. Walker, Barrett, Ellsworth, Cross, Cowan, Morgan, Schiro, Tupper, Collins, Schottstaedt, Trowbridge, Divanovich, Manson, Lamkin, Jorgensen, Robbins, Staniford, Tillman, Bell; McNamara of Bakersfield. Paine of Exeter and Dearborn of Madera.

Emmet Rixford of San Francisco discussed the subject of gastric and duodenal ulcers and carcinoma, including symptomatology and treatment with special reference to gastrectomy and gastroenterostomy. Rixford's paper was discussed by Pettis, Staniford, Cross and G. W. Walker.

Clinical cases were presented by D. H. Trowbridge.

On Tuesday evening, April 11, the regular meeting of the staff of the Fresno County Hospital was held at the hospital. T. Floyd Bell presented a paper on neuro-syphilis. The eye signs were discussed by T. F. Madden.

Glenn County Medical Society (reported by C. L. Terrill, secretary)—The society met at the Willows Sanitarium on March 21. Officers were elected for the year 1922 as follows: Etta Lund, president; C. L. Terrill, secretary-treasurer; delegate to State meeting in Yosemite, Etta Lund, with T. H. Brown, alternate.

J. L. Rawhauser of Willows has been appointed city health officer for 1922.

Madera County Medical Society (reported by Ray R. Dearborn, secretary)—This new society took the preliminary steps in organization at a meeting on March 28 in Madera. The secretary of the State Society was present and presided at the meeting. Dow H. Ransom was elected president; G. G. Hawkins, vice-president; Ray R. Dearborn, secretary-treasurer; C. L. A. Rinker, Smith A. Quimby and George G. Hawkins, members of the advisory board. Ransom was also elected delegate to the State meeting. Charter members in this youngest society are: John Allen and E. B. Allen of Raymond, and G. G. Hawkins, C. A. Robinson, C. L. A. Rinker, Smith A. Quimby, L. J. Calahan, Mary R. Butin and D. H. Ransom of Madera.

The society tentatively adopted the ideal constitution and by-laws for county societies as approved by the A. M. A.

Merced County (reported by Brett Davis, secretary)—The March meeting was held in the office of Brett Davis, the secretary, on March 28. Max Rothschild of San Francisco gave a talk, illustrated with lantern slides, on "Tuberculosis: Its Treatment with Partial Antigens." Rothschild divided tuberculosis into two classes: exudative and productive. These can be differentiated not only by physical examination, but by their reactions to injections of old tuberculin. The exudative type gives a slow reaction, lasting up to two weeks, with fever, while in the productive type the reaction is much more rapid and fever lasts only a few days. The speaker showed lantern slides illustrating the definite therapeutic value of artificial pneumothorax and also of the promising results of treatment by partial antigen.

The secretary of the State Society held an informal conference with the members of the society on matters pertaining to the welfare of medicine for the public and for the physicians.

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—The April meeting of the society was held in Redlands on the 4th with 25 members and 10 visitors present and 45 members absent. Alfred R. Roos was elected to membership and L. P. Barbour resigned. E. J. Eytinge read a paper on "Diversion of the Urinary Stream in Cancer of the Bladder," which was discussed by L. M. Coy. Henry Snure of Los Angeles presented the subject of "Pyelograms—Exhibition of Plates and Discussion of Their Interpretation and Value," discussed by Frank Folkins. A. B. Cecil of Los Angeles presented the subject of "One Hundred Consecutive Perineal Prostatectomies: a Critical Review." Discussion was opened by E. J. Eytinge.

The secretary's office is making strenuous efforts to enroll every eligible physician in San Bernardino as a society member.

San Diego County (reported by Robert Pollok, M. D.)—Recent meetings of the San Diego County Medical Society have been featured by the following papers: First: Renal Stone in a Lone Functioning Kidney, with report of case—L. H. Redelings, M. D. Second: Progress in Pediatrics—A. J. Thornton, M. D. Third: Appendicitis in the Female—H. P. Newman, M. D.

The Southern California Medical Society held its sixty-sixth semi-annual meeting in San Diego, on Friday and Saturday, April 7 and 8. The program was one of unusual excellence, and the spirit pervading the discussions in this society is extremely commendable. Every section of the country needs just such a society as this to offset the disadvantages of too much sectionalism in the program.

The medical library, true to library traditions, is finding it necessary to build in further bookstacks. The second quarterly meeting of the board of directors of the library was held in the library rooms on Monday, April 10.

The San Diego Society is planning a liberal representation at the Yosemite meeting of the State Society in May.

San Francisco County Medical Society (reported by LeRoy H. Briggs, secretary)—There were three meetings during the month of March. The general meeting on Tuesday, March 14, was devoted to discussion of the various aspects of appendicitis by I. S. Ingber, H. P. Hill and J. F. Cowan. The meeting on Tuesday, March 21, was the monthly meeting of the section on industrial medicine. At this meeting papers were read by C. L. Hoag, Sterling Bunnell, and J. M. Hamblin. The meeting on Tuesday, March 28, was by the section on eye, ear, nose, and throat. Papers were presented by E. C. Sewall, J. A. Bacher, A. J. Houston, J. H. McClelland, and W. F. Blake.

The San Francisco Hospital Colloquia (reported by Julian M. Wolfsohn).

1. **Tabes Dorsalis with Gastric Crises Complicated by Gastric Ulcer**—The patient, a woman, 36, was operated two and one-half years ago for gastric ulcer. The symptoms preceding operation were pain in the epigastric region, severe after meals and accompanied by vomiting of blood. The diagnosis was supported by X-ray findings and confirmed by operation.

On January 15 the patient again complained of epigastric pain extending down and around the abdomen to the back and accompanied by continual vomiting, nausea, retching. This attack had continued for two weeks at the time of the examination.

Examination disclosed Argyl Robertson pupils, anisocoria, left pupil smaller than the right. The gait was normal with the eyes closed. No Rombergism, but there was slight unsteadiness in walking backwards. No ataxia. Cranial nerves negative aside from the Argyl Robertson pupils. No analgesia in the distribution of the fifth nerve about the top of the nose. Motor system normal.

There was paraesthesia around the abdomen with pain in the pit of the stomach; analgesia from the first cervical segment below; no tactile anaesthesia; no disturbance of joint sense of big toes, diminished vibratory sense, and diminished deep sensibility; cerebro spinal fluid chemical and cytological tests negative; Wassermann x x; X-ray showed patent jejunum.

2. **Tabes Dorsalis with Ataxia**—An actor, age 46, more or less a drinker of spirits, was well until four years ago, when he suddenly became weak in his knees and fell to the ground. Upon regaining his feet he found that he staggered, and since that time has been unable to walk steadily.

No history of lancinating pain since the onset: but has had considerable painful tactile sensation over the body, worse in the lumbar region, spine, fingers, and feet. For three years has had diplopia and obstinate constipation has been present.

Examination shows marked sluggishness of both pupils to light; good accommodation; knee jerks sluggish; left ankle jerk absent, the right just obtained; no tenderness of calves to pressure; touching the skin very lightly in any part of the body causes considerable dysaesthesia in the form of painful sensations. There is no anaesthesia, but disturbance in the joint sense of the big toe: gait markedly ataxic; marked muscular hypotension; advanced Rombergism; more ataxia in the lower limbs than in the upper limbs; cerebro spinal fluid negative to chemical and cytological tests: Wassermann negative.

3. **Discussion**—The patient with gastric crises is especially interesting, because the association of gastric ulcer, which has been proved by operation, and gastric ulcer is extremely rare. Recent X-ray taken during the attack showed a spastic condition of the stomach with no other abnormality than the opening into the jejunum which was made during a previous operation.

The character of the pain, vomiting, and nausea; the fact that there were girdle sensations with the analgesia around the trunk, and especially the presence of a hyperalgesic zone to pressure just to the left of the fifth dorsal spine relegated this disturbance to the role of a gastric crises.

The attack lasted two weeks and then subsided completely. It is also intresting to note that gastric crises are usually not attended by much ataxia. This patient demonstrated the fact very well. The extent of analgesia is also worth noting because practically the whole body above the upper cervical segment is devoid of pain sensibility.

The second patient illustrates another tabetic condition. Very marked ataxia, but no lancinating pains, gastric crises, or girdle sensation. There was some disasthesia with loss of deep muscle sensibility resulting in clumsiness of movement and ataxia. Richter found, after examining a very large number of these cases histologically, that the area Nageotte was invaded by embryonic granulation tissue in which was found the living spirochaete. The pia-arachnoid protecting more fully the anterior root than the posterior root, rendering the latter more vulnerable to the toxins elaborated.

Degeneration within the spinal cord, and the posterior root zones is because there is no regeneration of the myalin in degenerating nerve fibers within the spinal cord due, most probably, to the absence of the sheath of Schwann.

San Luis Obispo County Medical Society (reported by G. David Kelker, Paso Robles)—The March meeting of the society was held at the Hotel Paso Robles March 9. After a very enjoyable dinner, Dr. Musgrave, secretary of the State Medical Society, presented to the members and guests some of the problems of the medical profession as a whole, and discussed in an informal conference way the local problems in hospitals, medicine, and public health of San Luis Obispo County.

March 10 was devoted to hospital work in Atascadero and San Luis Obispo, and another meeting of the county society was held in the latter city on the evening of the 10th.

The officers of the society for the year 1922 are Byron Y. Miller, president; Charles P. Proudfoot, vice-president, and G. L. Sobey, secretary-treasurer.

Santa Barbara County Medical Society (reported by V. C. Soper, secretary)—There were meetings of the society on March 11 and March 27, both meetings being held at the Cottage Hospital. At the meeting on March 11, W. E. Musgrave, secretary of the State Society, discussed the important problems confronting the medical profession. The meeting was essentially an informal question and answer conference, and many subjects of vital importance to the profession as a whole and to the local medical men in particular were discussed.

At the meeting on March 27, W. D. Sansum presented a paper on "Dietary Management of Nephritis." H. L. Schurmeier's paper was on "Congenital Deformities."

On Monday evening, March 20, many members of the society attended the lecture by Mr. Harold Bayne on "The Truth About Vivisection."

Santa Clara County Society (reported by E. P. Cook, secretary)—The March meeting of the society was held at the Santa Clara County Hospital on March 15, with about forty members present. Doxey Wilson spoke briefly of the growth of the County Hospital and showed graphic charts representing the growth of the hospital and the clinic, with the distribution of cases and ages of patients admitted.

Mr. A. B. Wastell, executive secretary of the San Jose Hospital, spoke briefly regarding the local hospital day to be held on March 20, on which date ground was to be broken for the new San Jose Hospital.

J. B. Bullitt presented a child with a large vascular nevus on the body which he was treating by means of X-ray and radium.

Frederick Curtiss discussed the technique of mandibular injection, with its resulting area of anesthesia.

Louis Boonshaft discussed artificial pneumothorax, at the same time demonstrating the method on a patient.

Doxey Wilson presented a patient whom the members of the society saw one year ago, shortly following the removal of a large portion of the large intestine and a small portion of the small intestine.

George A. Gray read a paper on the non-surgical drainage of the gall-bladder and demonstrated the method.

E. P. Cook discussed the various uses of the puncture of the longitudinal sinus in infants and demonstrated the method of obtaining blood via this route.

Stanislaus County (reported by R. E. Maxwell, secretary)—R. E. Maxwell of Modesto has been appointed county physician and health officer of Stanislaus County to succeed J. L. Hennemuth, who has acted in this capacity for nine years.

Tulare County Medical Society (reported by Elmo R. Zumwalt, secretary)—The medical society met at Hotel Johnson, Visalia, on March 23. The meeting opened with a dinner at which were present twenty-six out of thirty-seven members and six guests. The following officers were elected for the current year: A. W. Preston, president; C. A. Tillotson, vice-president; E. R. Zumwalt, secretary-treasurer; Austin Miller, delegate to State meeting in Yosemite and C. A. Tillotson, alternate.

J. N. Blood was admitted to membership in the society.

W. E. Musgrave, secretary to the State Society, was present and held an informal conference on subjects of importance to medical men everywhere. A question and answer conference about local conditions in Tulare County was continued until very late in the evening. The constituent societies of the state will surely profit by this visit of the state secretary and it will be stimulating to that spirit of co-operation necessary to us all.

The health center clinic and hospital at Visalia is now operating.

Men who have spent many years in securing their legitimate education as physicians, as well as the best element of the citizens of Tulare County, are very much pleased and gratified over the decision of Judge Wallace in sentencing an unlicensed chiropractor to a fine of $500 or an extended jail sentence.

Physician Wanted for Atwater, California—Atwater is a town of 700 inhabitants, located seven miles from Merced. Private offices have been fixed up for a physician and a dentist. The dentist is already located in the town. Any physician interested in the proposition should write to Chadwick & Chadwick, Atwater, California.

ST. LOUIS MEETING OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association is a scientific organization, but is composed of members with more than the average amount of "humanity" in their makeup, with social elements too long repressed. These members are weary from bearing the responsibility of many human lives. Instead of having play time they have become public teachers with no recess. The local entertainment committee of the A. M. A. have been busy preparing to show these visitors true St. Louis hospitality and to provide for them such diversions as will be both restful and entertaining.

The golfers will arrive early, in order to participate in the annual tournament on Monday, May 22.

Tuesday evening the opening meeting will be held in the Odean, and arrangements are being made to have the music and addresses transmitted by radio to various parts of the city and to distant cities.

Wednesday evening is given over to banquets such as Alumni, Fraternal, Sectional, etc. On this evening, provision is being made to entertain the visiting ladies and those doctors who are not engaged at the Alumni and Fraternity dinners at one of St. Louis' noted moving picture shows, with special musical and other features for the occasion.

On Thursday afternoon the medical department of Washington University is giving a special Tea on the grounds of the institution. Thursday evening will be given over entirely to the President's reception and it is hoped that as many as possible of the doctors and their ladies will grace the occasion with their presence.

The committee, after visiting the offices of the Mayor and the Director of Public Welfare and being assured of their co-operation, have decided to reserve until Friday evening the chief feature of their entertainment by giving a special program for the entire association in the unique open-air Municipal opera house, which has a comfortable seating capacity of ten thousand. The location of the opera house in the heart of Forest Park, with its special lighting effect made possible by the natural foliage of the forest, can be appreciated only by those who visit it at night. It is the hope of the committee that every visitor at the convention will remain in St. Louis through Friday evening.

The Ladies Entertainment Committee, under the leadership of Mrs. Willard Bartlett, has arranged to take immediate charge of every lady visitor who may be persuaded to accompany the medical member of the family to the convention. They need have no fear of being left alone while the doctor is attending the scientific meetings for practically every hour of their time has been arranged for and it is hoped that many more ladies than usual will visit the "City of Homes"—"The Friendly City."

A special visit to Missouri's Botannical Gardens is being arranged, and will be an important item in the entertainment program. Among other features to be shown will be an old Italian herb garden. St. Louis is justly proud of its world-famous Botannical Garden.

Take the whole week off, Doctor, and spend it in St. Louis. It will be time well spent. You may lose a patient, some may get well during your absence, but your increased vigor when you get back will abundantly make up for any losses. Come to our party for one full week.

Dr. C. E. Burford, 3525 Pine street, is chairman of the Entertainment Committee.

BOOKS RECEIVED

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for review in the interests of our readers and as space permits.

Infant Feeding. By Clifford G. Grulee, M. D., LL. D., Associate Professor and Acting Head Department of Pediatrics at Rush Medical College. Fourth edition, thoroughly revised. Octavo of 397 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1922. Cloth, $4.50 net.

Psychoanalysis: Its Theories and Practical Application. By A. A. Brill, Ph. B., M. D. Lecturer on Psychoanalysis and Abnormal Psychology, New York University. Third edition, thoroughly revised. Octavo of 468 pages. Philadelphia and London: W. B. Saunders Company, 1922. Cloth, $5 net.

A Text-Book of General Bacteriology. By Edwin O. Jordan, Ph. D., Professor of Bacteriology in the University of Chicago and in the Rush Medical College. Seventh edition, thoroughly revised. Octavo of 744 pages, fully illustrated. Philadelphia and London: W. B. Saunders Company. 1921. Cloth, $5 net.

Clinical Electrocardiography. By Frederick A. Willius, M. D. Section on Clinical Electrocardiography, The Mayo Clinic, Rochester, Minn., and the Mayo Foundation, University of Minnesota. Octavo of 188 pages with 185 illustrations. Philadelphia and London: W. B. Saunders Company, 1922. Cloth, $5 net.

Diseases of the Eye. A Handbook of Ophthalmic Practice for Students and Practitioners. By George E. deSchweinitz, M. D., LL. D., Professor of Ophthalmology in the University of Pennsylvania. Ninth edition, reset. Octavo of 832 pages with 415 text illustrations and seven colored plates. Philadelphia and London: W. B. Saunders Company, 1921. Cloth, $10 net.

The Medical Clinics of North America (Issued Serially, one number every other month) Volume V, Number 4, January, 1922. By New York Internists. Octavo of 214 pages, with 38 illustrations. Per clinic year (July, 1921, to May, 1922). Paper, $12 net; cloth, $16 net. Philadelphia and London: W. B. Saunders Company.

Clinical Tuberculosis, by Francis Marion Pottenger, A. M., M. D., LL.D., medical director, Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, Cal. With a chapter on laboratory methods by Joseph Elbert Pottenger, A. B., M. D., assistant medical director and director of the laboratory, Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, Cal. Two volumes. Second edition. St. Louis: C. V. Mosby Company. 1922.

The Etiology and Pathology of Typhus. Being the main report of the Typhus Research Commission of the League of Red Cross Societies of Poland. By S. Burt Wolbach, John L. Todd, and Francis W. Palfrey. Published by The League of Red Cross Societies at the Harvard University Press, Cambridge, Mass. 1922.

BOOK REVIEW

Ephraim McDowell, "Father of Ovariotomy" and Founder of Abdominal Surgery. With an appendix on Jane Todd Crawford. By August Schachner, M. D., F. A. C. Philadelphia and London: J. B. Lippincott Company. 1921.

A most interesting and curious study of the life of this surgical pioneer. It should have a special interest to Californians. California pioneers and Kentucky back woodsmen—these were the men who made the first ventures into the unexplored fields of abdominal surgery.

Instead of the Saturday Evening Post take this book with you the next time you spend a few days on a Pullman. L. E.

A Text-Book of Physiology: For Medical Students and Physicians. By William H. Howell, Ph. D., M. D., Professor of Physiology, Johns Hopkins University, Baltimore. Eighth edition, thoroughly revised. Octavo of 1053 pages, 308 illustrations. Philadelphia and London: W. B. Saunders Company. 1921. Cloth, $6.50.

In this new edition of the standard American text-book, an effort has been made to emphasize the hygienic application of physiology. The book is too good and to well known to need further recommendation. L. E.

The Submucous Resection of the Nasal Septum. By W. Meddaugh Dunning, M. D. New York: Surgery Publishing Company. 1921.

A little monograph on the author's method. Good illustrations and a lot of practical hints but rather scant matter to make a book of. L. E.

Neoplastic Diseases. A treatise on Tumors. By James Ewing, M. D., Sc. D., Professor of Pathology at Cornell University Medical College, New York City. Second edition, revised and enlarged. Octavo of 1054 pages with 514 illustrations. Philadelphia and London: W. B. Saunders Company, 1922. Cloth, $12 net.

A new edition of what is by far the best book on cancer in the English language. Both text and illustrations make it invaluable to the surgical pathologist. L. E.

The Medical Interpreter. Selected practical foreign medical and surgical literature. By Albert Allemann, A. B., M. D. Chicago: The Medical Interpreter. 1921.

Short articles snatched haphazard from foreign journals dealing on one page with "hair falling," with a recipe for the same, and hemorrhoids; on another with gall-bladders and gleet. The result needs no description. It reminds one of the Universal Encyclopedia and Farmers' Home Companion whose itinerant peddlers grandpa used to impale upon a pitchfork. L. E.

Protein Therapy and Non-specific Resistance. By William F. Petersen, M. D., Associate in Pathology, University of Illinois, College of Medicine, Chicago, Ill. With an introduction by Joseph L. Miller, M. D., Professor of Medicine, Rush Medical College, University of Chicago, Chicago, Ill. New York: Macmillan Company. 1922.

The volume is very complete but the matter of which it treats stands upon so uncertain a foundation that this very detailed work will have but a limited audience. L. E.

NEW MEMBERS

John D. Hartley, San Diego; Thos. F. Thorp, San Juan Bautista; Emma E. McKay, Hollister; Chester W. Merrill, Hollister; Richard W. O'Bannon, Hollister; Joseph M. O'Donnell, Hollister; H. B. Stevens, San Francisco; Robin L. Richards, San Francisco; John E. Wilson, Los Angeles; R. Umesawa, Los Angeles; Homer S. Wilson, Lankershim; James Johnston, Los Angeles; Florence Keller, Los Angeles; G. F. Harding, Ocean Park; A. V. Stephenson, Long Beach; Frank H. Chase, Los Angeles.

DEATHS

Bolton, Manzanito B. Died in Quincy, Calif., March 27, 1922. Was a graduate of the California Medical College, California, 1899, and licensed same year. Age 44.

Bryant, George Waldo. Died March 14, 1922, in Truckee, Calif. Was a graduate of the California Medical College, California, 1897. Licensed in 1897. Cause of death, influenza.

Bennett, E. G. Died in Petaluma, Calif., February 21, 1922. Age 68. Was a graduate of Rush Medical College, Ill., 1878. Licensed in California, 1898. Was a member of Sonoma County Medical Society.

Cottingham, R. C. Died in San Francisco, March 11, 1922. Was a graduate of the College Medical University of Missouri, at Columbia, 1883. Licensed in California, 1885.

Chapin, J. E. Died in Redwood City, California, March 23, 1922. Was a graduate of the Washington University, St. Louis, Mo., 1909. Licensed in California, 1912. Was a member of San Mateo County Medical Society.

Hardy, Oscar R. Died in Los Angeles, March 5, 1922. Age 41. Was a graduate of Northwestern University Medical School, Chicago, 1912. Licensed in California, 1920.

Jones, Frank C. Died in Los Angeles, March 2[illegible], 1922. Was a graduate of the University of Michigan, 1880. Licensed in California, 1914.

Neal, Harrison. Died in San Miguel, Calif., March 11, 1922. Was a graduate of Jefferson Medical College, Pa., 1859. Licensed in California, 1876. Was 87 years old.

Rowland, F. F. Died in Pasadena, Calif., March 12, 1922. Was 74 years old. A graduate of Jefferson Medical College, Pa., 1873. Licensed in California, 1888.

VOL. XX JUNE, 1922 No. 6

SOME ACCOMPLISHMENTS AND PROBLEMS OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA*

By JOHN H. GRAVES, M. D., San Francisco

Following the custom of my predecessors in the Presidential office, I delivered an inaugural address last year at Coronado that differs from those of former years in that it took less than one minute of your time. Its brevity was not due to any lack of appreciation of the signal honor you conferred upon me, nor was it due to any lack of understanding of the many pressing problems that await solution. It was because of a definite knowledge of the great volume of work that the welfare of the Society demanded should be completed without delay and was an effort to establish a time-saving precedent.

Today, after one year as President-elect and one year in the office of President, it becomes my duty to render a brief account of my stewardship of your interests by describing as briefly as possible the year's work and calling to your attention the more important measures that demand action by this Society.

More than half a century has elapsed since a small group, devoted to the advancement of their profession and dedicated to the relief of human suffering, organized the Medical Society of the State of California. When in 1917 its membership had grown to 2400 and Dr. Philip Mills Jones, who, after serving for several successive years as Secretary, had been removed by death, there were many in our ranks who believed that our Society had reached the zenith of its activities and the maximum in membership, and yet on the first day of May of the present year we find the names of over 3500 of the physicians of California on the membership roll of this organization.

We find its Journal enlarged in size, enhanced in value as a scientific publication, with increased circulation, and for the first time in its history, paying its way.

The recently adopted policy of giving papers read before the County Societies the same standing, with equal chance for publication, with those read before the annual meeting of the State Society has resulted not only in elevating the standard and increasing the value of papers contributed to the various county units as well as to the State Society, but has given to the Journal more valuable papers than it can possibly hope to publish.

Among the year's activities should be mentioned the Extension Lecture Service, which brings to the various County Societies men who have made special studies in certain subjects and disseminate among the members of the profession the latest knowledge pertaining thereto by written papers and scientific demonstrations. To this splendid corps of teachers, true to the first principles of their profession, volunteering as they do from every section of the State, permit me, as the spokesman of the membership of this Society, to express my grateful appreciation and a fervent wish for the continuance of their efforts.

Any review of the year's work would be sadly deficient and woefully incomplete without at least a brief review of some of the more important of the many activities of our most capable Secretary. In addition to the crushing work in his office, such as answering thousands of letters and telegrams, holding conferences by the hundreds, locating over one hundred capable physicians in the localities that needed much their services, supplying hundreds of technical assistants to doctors and hospitals, and other hundreds of specially trained and qualified nurses, he has in some mysterious manner found time to travel thousands of miles up and down this State serving you, and through you, the people of California. In twenty-four days this devoted man traveled by automobile over 1600 miles, met over 1500 physicians, spoke before twenty County Medical Societies, visited and assisted in the solution of the problems of over seventy hospitals. During the year he has visited at least once, and in some instances several times, thirty-four of the forty-one County Medical Societies in this State. He assisted in organizing one new society and resuscitated and brought back to vigorous health one that had been in such a comatose state that it had not held a meeting for over five years.

What can we do or say that will properly express our appreciation for a man who, with such zeal and energy and intelligence, dedicates his remarkable abilities to our welfare?

Were it not for the fact that Mr. Hartley F. Peart, the Attorney of the State Medical Society, is to address you this morning on some of the problems of medical defense, I would dwell upon the wonderful record and the immense value to the medical profession of our legal department. It is an outstanding feature in the activities of this organization and no member can afford to leave this year's meeting without being certain that his name is on the list of members of the Indemnity Defense Fund. For the success of this work our Society is most deeply indebted to Mr. Peart, who, in this as in all other matters in which we find his advice necessary, has displayed a legal ability and a loyalty to the ideals of our

* President's Annual Address, delivered at the Annual Meeting of the Medical Society of the State of California, May 18, 1922.

profession greater, I am sure, than those who are not thoroughly familiar with his work can appreciate.

To Mr. Hubert Morrow, who so ably cares for the interests of the fund south of Tehachapi, all praise and thanks are due. The work for hospital betterment, which has been productive of such phenomenal results, has been possible only because of the close co-operation of this Society with the section appointed for that work, by the League for the Conservation of Public Health. In fact, much of the constructive work of our Society, and I think much of the constructive work accomplished by the League for the Conservation of Public Health, was made possible by the close and harmonious relation that exists between these two splendid organizations.

With this work proceeding as successfully and harmoniously for the next year as it has for the past year, the hospital service to the public of California in 1923 will be as much better than that rendered at present as our present hospital service is superior to that rendered in most of the States at the present time.

A year ago it was decided to call a meeting of the presidents and secretaries of the various County Societies, with the understanding that if there was reasonable response to the invitation, a semi-annual meeting of presidents and secretaries of the various county units would be instituted as a permanent feature. What was an experiment a year ago is now a brilliant success.

At the meeting of the officers of the Societies held in San Francisco this past winter, thirty-four of the forty-two County Societies were represented by forty-five officers. The increased efficiency of our organization as a result of the meeting of the various units has been made manifest in ways too numerous to mention at this time. The work of the Industrial Medicine Committee has gone on with sure but necessarily slow progress. This will be thoroughly dealt with by the chairman of that committee, Dr. Parkinson. So I will not comment further on it.

So much for a fractional and extremely sketchy review of the year's work.

And now may I beg your close attention to the brief mention of two subjects which have occupied a most prominent place in my mind during the past year? The first is that of medical education and training. It will be the subject of a paper that will be read before this body tomorrow morning by Dr. Ray Lyman Wilbur, President of Stanford University. As a teacher of medicine, as a clinician, and as the executive head of a great University, I am certain, though I know nothing of the contents of his paper, that it will present many new thoughts in a concise and masterful manner; but if I may be permitted to state some personal views, I will call your attention to the fact that the men and women of the medical profession who are engaged in active practice serving the citizens of California, by returning them to health in the shortest possible space of time when stricken with illness or injury, are not taking the active interest that they should in the education and training of those who are to be their successors. No group can understand or appreciate as well as you, the medical practitioners of California, the real need in the way of medical and surgical service of that great body of worthwhile American citizens that looms so large between the thin line of millionaires on one side and the thin line of paupers on the other side.

This great group, the real group, that is so seldom seen in the teaching clinic or in the $20-a-day room of the exclusive hospitals, this self-respecting, able to pay, willing to pay, business, salary-earning and farm-owning people need more good doctors, fewer poor doctors and fewer specialists, and any doctor can call himself a specialist if he so desires. We need specialists and the people need them, but with numbers diminished and qualifications increased.

In a supplement to a report on medical education and hospitals of the American Medical Association in Boston, Arthur Dean Bevan said: "The Council on Medical Education and Hospitals of the A. M. A. believes that the time has arrived when we must reorganize our scheme of undergraduate medical education so as to give the undergraduate a broader and simpler training in medicine which will make him a better general practitioner. That means simplifying the course under three clinical heads—medicine, surgery, and obstetrics. We must make the effort to train the man who is going into a community to do general practice in the broadest and best possible way. We feel, moreover, that the general practitioner is by all odds the most important man in medicine. Numerically he should be at least 90 per cent of the medical profession. This broadly trained man is the man who can take better care for the health of the community than can any group of specialists no matter how competent."

Not only do I heartily subscribe to the statements of Dr. Bevan, but I respectfully request of my successor to this office that he use his influence to create interest in the subject among the great body of the profession, and I would suggest that at least once a year each County Society requests from one of its members not engaged in teaching, a paper on medical education. This paper, filed in the office of the Journal, would make interesting reading and, I believe, profitable study for the teachers in the medical departments of our universities.

The other subject, like socialism, is somewhat difficult to define. It always reminds me of the various descriptions of the elephant by the six blind men of Hindustan. It is generally alluded to as State Medicine and embraces all such things as compulsory Health Insurance, Diagnostic and Health Centers, controlled and operated by political power. It is an insidious effort by certain misguided and sometimes sinister influences to control by political power the practice of our profession.

It is an attempt under the specious plea of bringing medical aid to the public, to regulate and control not only the practice of the profession, but the activities of the private citizen.

Your time is too limited to permit of an ex-

tended discussion of this most important subject, but let me warn you against lending your support to measures, however plausible, on cursory observation, which may, like the wolf in sheep's clothing, prove to be radicalism covered with the cloak of philanthropy. The teachings of Jefferson, the philosophy of Franklin, and the wisdom of Washington are still more acceptable to most American hearts than the doctrine of Karl Marx.

It is a pleasure to express our appreciation to our distinguished guests, both of our own profession and those distinguished gentlemen, the Hon. John O'Connell, Secretary of the State Labor Association, and the Hon. John D. Fredericks, President of the Los Angeles Chamber of Commerce, for their presence at this meeting. Their intelligent and sympathetic interest in our profession and in our public health problems is gratefully acknowledged by the members of this Society and the League for the Conservation of Public Health.

In conclusion, here in this stupendous amphitheatre, this great gorge chiseled by Almighty God and discovered by a member of our own profession, here by these great waterfalls that were falling when the Pyramids were built, when Christ was crucified, when the fight at Lexington and Concord was news, that will be falling when the events of today have passed into the dim twilight of tradition and disappeared in the black night of oblivion, I desire with all sincerity to express my heartfelt thanks for the great honor which you conferred upon me when you made me the chief executive of your Society, and in saying farewell, to assure you that the work of the years past has been a labor of love and a feeble effort to return in some small way just a little for the very great benefits bestowed on me by members of our profession.

DUBUQUE COUNTY MEDICAL SOCIETY ASSUMES CARE OF POOR

The Dubuque County (Iowa) Medical Society and the County Board of Supervisors have entered into an agreement whereby the medical men of Dubuque County agree to render aid to the indigent poor of the county for a year at the stipulated price of $3,250. The doctors have agreed to each serve the county for a period of ten days, during which times they attend all persons who are county charges free of cost to the individual. This service only applies to the indigent poor. The specialists of the city are allotted specific times when they are subject to call for the care of indigent poor. The money received in payment for this service does not go to the individual physician. A part of it is used by the society to purchase equipment to make more interesting their monthly meetings, and to pay the expenses of experts who may be brought from a distance to address the society.—Illinois Medical Journal, April, 1922.

Medical Veterans of the World War—Those physicians who served at the Letterman General Hospital during the war are urged to send their latest addresses to Dr. A. H. Reinstein, Flood Building, San Francisco, for another reunion dinner is being planned and a full attendance is desired.

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.

PRESIDENT'S ADDRESS ANNUAL MEETING LOS ANGELES COUNTY MEDICAL ASSOCIATION DECEMBER 15, 1921—GOVERNMENTAL ACTIVITIES AND TENDENCIES IN THE HEALTH FIELD

By WALTER V. BREM, M. D., Los Angeles, Calif.

It is becoming increasingly apparent that large numbers of persons are feeling great irritation and dissatisfaction on account of present conditions of medical practice. Two of the causes of this dissatisfaction are:

1. The enormous increase of knowledge during the past fifty years and the tremendous output of medical literature have rendered it impossible for one physician to cover adequately the vast field; and so there has come about the development of the specialists. These specialists have worked hitherto largely independently of one another, and, in order to secure their services, a patient must often be sent from pillar to post at great inconvenience and a great expenditure of time and energy. Naturally, such patients feel considerable irritation, and, more and more, large groups are seeking a simpler solution of their problem.

2. This irritation is increased by the conditions determining professional fees, inability to estimate the probable cost of sickness, the high cost of sickness, especially for the large group of persons with only moderate incomes, and the frequent inefficiency of the present system of practice. Under present conditions, the factors entering into the determination of a fee for professional services are so many and intangible that it is practically impossible to take any steps toward working out an acceptable schedule. Each physician places his own valuation upon the services rendered. Some of the factors entering into such a valuation are: The skill and experience of the physician; the reputation of the physician and the demand for his services; the character of the services rendered; the result of the treatment, i. e., the benefit the patient receives; the customary charges in the community for such services; the legal and professional hazards involved; the financial status of the patient.

It can be appreciated readily that most of these factors are so intangible that they cannot be used

as a basis for determining a working schedule, while the last factor, "the financial status of the patient," involves the question of the right of one individual to demand that another shall liquidate the debt of, or pay for the charity received by, a third person.

These conditions have led to wide discussions, not only by the laity, but also by those of the medical profession who are interested in the problems of medical economics and who see grave danger ahead if the problems are not met with forethought and vision. In some foreign countries actual experiments by governments have been made toward their solution. So the unfortunate term of "State Medicine" has arisen without any definite understanding of its meaning.

As a matter of fact any governmental activity in the health field is State medicine, and some of these activities are certainly founded upon sound principles and should be supported. Other possible extensions of governmental activities may be grave menaces to the public health, and incidentally to the medical profession. I say "incidentally" to the medical profession because it is axiomatic that such broad questions cannot be justly solved from the point of view of the welfare of a special group, but only upon the basis of the general welfare.

It has seemed appropriate, therefore, to review briefly present governmental activities in the health field, to indicate possible extensions, and to state the problems worthy of our consideration.

PRESENT GOVERNMENTAL HEALTH ACTIVITIES

1. *Preventive medicine.* In this field we cannot deny the value of governmental activity. The main plank in the platform, so to speak, of the medical profession in the municipal election in Los Angeles on June 7, 1921, was as follows: "One of the highest functions of government is the protection and advancement of the health of the people both for economic reasons and to promote the happiness and virility of its citizens."

Governmental activities in the field of preventive medicine may be classified as follows:

Sanitary engineering and control of health problems in community services.

Quarantine.

Vaccination against smallpox, typhoid and diphtheria.

Consultation in contagious diseases.

Vital statistics.

Venereal prophylaxis, quarantine and treatment of patients under quarantine.

Inspection, examination and physical training of school children.

Education in the elementary laws of health and personal hygiene.

Epidemiological research.

2. *Medical education in State universities.*

3. *Medical services of the Army, Navy and Public Health Service.*

4. *Hospitals for indigents.*

5. *Psychopathic institutions, contagious disease hospitals and sanitoria, and emergency hospitals.*

6. *Medical care in government institutions, as penitentiaries.*

7. *Restriction or definition of those who care for the sick, i. e., the issuance of certificates on the basis of educational standards by State Medical Examining Boards.*

8. *Industrial Accident Insurance.*

Numbers 1, 2, 3, 4, 5, and 6, I assume require no discussion, for their value and legitimacy seem undisputed.

Number 7 invites discussion as to whether the medical practice act should restrict the care of the sick to those qualifying by carefully determined educational standards, or should it only define for the benefit of the public those who have qualified and allow others to practice at will, restraining them only from false pretensions regarding qualifications? Those who advocate the latter view appear to lose sight of the fact that efficient quarantine regulations by health departments depend upon the ability of practitioners to diagnose disease and by prompt reports to aid in checking epidemics. Those in the field should form a trained branch of the army evolved for the combat of disease, and the efficiency and morale of the army should not be lowered by permitting untrained men in its ranks.

Another phase suitable for discussion is the advisability of the enforcement of the act by the Medical Examining Board. It has been argued with reason that the board is an educational and not an executive body, that enforcement of the act should be a function of the regular legal machinery, and that enforcement by the board serves to raise the cry of "persecution" by offenders, and thus confuses and arouses suspicion in the public mind.

Number 8, industrial accident insurance, is just emerging from the experimental stage. It provides in California that employers must assume the risk from accident to employes. The compensation is determined by the State Industrial Accident Commission. The employer may carry the risk himself, he may insure in non-official insurance companies, or he may insure with the State Compensation Fund. The last is, in effect, a government insurance company, and it involves the question of governmental invasion of the field of business. If this works out for the benefit of the community, however, there should be no ground for criticism on that score. There may arise, however, legitimate differences of opinion regarding details of the *modus operandi*, but time must be allowed for adjustments, and it would seem wise for us to support the experiment, letting it go forward aided by our sympathetic consideration and counsel.

POSSIBLE EXTENSIONS OF GOVERNMENTAL ACTIVITIES

The term, "State Medicine" as ordinarily used refers, I take it, to certain possible extensions of governmental health activities.

1. Compulsory health insurance.

2. Zoning of communities and distribution of physicians.

3. "Health centers" for the treatment of the indigent sick.

4. Pay clinics with physicians employed by the Government.

5. Complete control of medical practice as a public utility, governmental employment of all physicians, and ownership or control of all health institutions (hospitals, etc.).

(1) *Compulsory health insurance.* The proponents of compulsory health insurance have advocated the following lines of experiment:

(a) Industrial health insurance, along the line of industrial accident insurance, in which the employer now pays for the whole risk.

(b) Industrial health insurance, in which the employer and employe share the risk in certain proportion. This was the basis of the compulsory health insurance initiative which was defeated in California in 1918 by a majority of 224,000.

(c) Health insurance, in which everyone with an income below a certain figure must carry his own insurance with possible assistance from the government, e. g., the "Capitation" fee in England.

In all these instances the government may or may not form an official insurance company, like the State Compensation Fund. If it should, it would control, or enter into competition with other insurance companies in controlling, the professional services rendered. In England the government has controlled the professional services and paid the physicians from the "Capitation" fees. There seems to be widespread dissatisfaction in England both among the laity and the medical profession, and there has been serious discussion regarding the abandonment of the experiment. Aside from the criticism of the enormous expense to government, which does not seem a serious criticism, the great objections have been that the laity complain of perfunctory service and inadequate medical treatment; that the system is developing large numbers of neurotic persons, who, because the service has already been paid for and costs nothing additional, run to the doctor with every conceivable ailment real or imaginary; and the dissatisfaction of the public has resulted in an enormous increase of cultism and quackery.

Such a situation is exactly what we would anticipate under compulsory health insurance, i. e., we would look forward to inferior professional services and to an undermining of the health morale and therapeutic conceptions of the people. Moreover, the people would not retain the right which they so highly prize of selecting their own physician and of experiencing a certain valued relation that should exist between a patient and his chosen physician. A further objection advanced to government controlled medical practice is that it undermines initiative, does not recognize merit, does not stimulate investigation, and, in general, tends to paralyze scientific progress.

These criticisms, if valid, which they undoubtedly are, constitute insuperable objections to compulsory health insurance, disadvantages against which the apparent advantage of smaller professional fees should have no weight. It is imperative, therefore, for the sake of the public welfare and the progress of scientific medicine to oppose any tendencies toward such a program.

(2) *Zoning of communities and distribution of physicians.* There is no question but that the distribution of physicians is a grave matter, and that rural communities suffer from the present tendency of physicians to congregate in the larger urban communities. Governmental interference, however, would be an infringement upon an individual's right to live and work in the place of his choice, and it should be resisted. However, the problem is a proper one for the organized profession to consider, and the American Medical Association is now collecting data in an effort to find a solution by persuasion and dissemination of information rather than by force.

(3) *"Health Centers" for the treatment of the indigent sick.* It may be argued in favor of such health centers that they are but an extension of the idea of hospitals for the care of the indigent sick. The government takes care of poor hospital patients, why not also of ambulatory patients? The psychology of the two situations is different. We know that the American people will apply for admission to a County hospital only when they are financially embarassed, and in definite need. But experience has shown that this is not true of a free clinic, to enter which well-to-do patients will sometimes dress in old clothes, take off their diamond rings, and leave their automobiles around the corner out of sight. Would not government free clinics almost certainly invite such behavior, stimulate a desire to get something for nothing, tend to create a neurotic group, and generally undermine the pride and morale of large numbers of the people?

(4) *Pay clinics with physicians employed by the government.* Such an undertaking by the government would lead logically and inevitably to an extension of activity which would cover the whole field of medicine. Therefore, the discussion of government pay clinics may be included under the next head.

(5) *Complete control of medical practice as a public utility, governmental employment of all physicians, and government ownership or control of all health institutions (hospitals, etc.).*

The questions that would be involved are:

(a) Would the public receive better medical attention? No.

(b) Would the cost of sickness be reduced? No.

(c) Would disability from sickness be reduced? No.

(d) Would the progress of knowledge be advanced or retarded? Retarded.

(e) Would the service rendered by the medical profession be more or less efficient? Less.

(f) Would a premium be placed upon mediocrity and political pull? Yes.
(g) Would the system be swamped in "red tape" and "graft"? Yes.
(h) Is it what the people want? No.

The discussion of compulsory health insurance applies with equal force to most of these questions, and I would answer them categorically as indicated above.

The undertaking would be an enormous one, compared with which the medical service of the Army during the Great War would be but a minor affair. Enormous funds would be involved, great political machines would be built up, red tape and graft would be intolerable, and the morale of the forces fighting against disease would be undermined.

Have we confidence enough in the machinery of government and in our politicians to consider for one moment entrusting to them our patients, our profession, ourselves? Have we not already had sufficient evidence of the inadequacy of government in large business undertakings? Yet the previous problems that have been met with are of elementary simplicity compared with the problems to be met in governmental organization and control of medical practice.

Medical practice is in a stage of evolution. Conditions have practically wiped out the old family physician and it would seem impossible for him to become re-established in his old position of importance, although there are authorities who think that his re-establishment would solve many of the problems of practice. The independent specialist has largely replaced the family physician, and has brought with him vexing problems with dangerous potentialities. New complications have arisen and must be squarely faced, and a further transition in the practice of medicine must take place.

The question is, shall the transition be a natural one of evolution resulting from study and wide experiment by numbers of well trained thinking men, or will impatient people lay violent hands upon the problem and demand that it be entrusted to government agencies in a gigantic and dangerous experiment? We are, I may say, unqualifiedly opposed to such an experiment, which, we believe, would seriously imperil the health and happiness of the community.

PROGRAM PROPOSED

We may well be asked, if we reject government agencies, what constructive program have we to propose? Many answers will be given, for the problem is a difficult and intricate one and experimentation must be broad. However, two main lines of experiment seem to be developing. The first is the group practice idea, some form of which would seem to be a logical development in order to bring together the specialists, thus co-ordinating effort and increasing efficiency, reducing overhead expenses, and reducing and stabilizing professional fees. Such groups could care for a far greater number of patients and far more efficiently than could the individuals of the groups if scattered, and better medical practice at a much reduced cost might be the result.

The second line is the idea of the endowed hospital as a community center from which radiate health ideals through all its manifold services. Such a hospital should be organized to care for the sick at a cost commensurate with their financial resources, the deficit to be covered by the interest on the endowment. The governors of the hospital might well be selected from the group of donors to the endowment fund, donors who would be men of broad vision, vitally interested in the community life and the successful service of the hospital.

Such a great hospital would serve as a model for smaller communities and would stimulate widely the development of numerous hospitals along sound lines, that is, hospitals conceived in the spirit of community service.

CONCLUSIONS

"State Medicine" is an unfortunate term. It may be defined, however, as referring to any or all of the following extensions of governmental activity in the health field—compulsory health insurance, distribution of physicians, free and pay clinics, and complete control of medical practice as a public utility.

The medical profession believes that such an extension would be a perilous experiment and inimical to the public welfare, and it is unqualifiedly opposed to any activity tending toward such a program.

NEWSPAPER CARDS OF DOCTORS

A recent examination of many newspapers of the State shows that a certain percentage of the physicians of most county societies carry their professional cards in their local newspapers. The printed ethics or moral code of the medical profession authorizes cards of this character, provided they are sanctioned by the county society and provided further that no card shall express anything more than the physician's name, office hours, telephone and the limitations, if any, placed upon his practice. A certain amount of this character of advertising is going on in more than thirty counties of the state in a large number of papers. In most instances, the cards are thrown in indiscriminately with all sorts of business and professional cards, as well as those of irregular and frequently unlicensed practitioners.

If it is the policy of our county societies to engage in this form of advertising, it is suggested to them that they do it in a dignified manner, by resolution of the county society and by control of the wording in the cards by the committee on censorship, and, most important of all, by insisting on these cards being inserted "boxed" under the name of "County Medical Society Directory." The best example seen in any county paper from a recent survey is that of Stanislaus County, where the cards of many of the members are "boxed," thus controlling the space and distinguishing it from every other advertisement in the paper. Societies or officers interested in this question might secure copies of the Modesto papers by addressing Dr. R. E. Maxwell, secretary of the Stanislaus County Medical Society, Modesto. Nothing in this editorial should be construed as an endorsement by the State Society or the editor of the policy of placing cards in lay publications.

WHAT THE GENERAL PRACTITIONER CAN DO TO IMPROVE THE DIAGNOSIS AND TREATMENT OF DISEASES OF CHILDREN *

By LANGLEY PORTER, M. D., San Francisco

In the time allotted, some part of the matter involved can be touched upon, and as the specialty of Pediatrics is, in reality, no specialty at all, but merely the practice of general medicine among those of tender age, physicians may pardon a pediatrist if he joins in such a discussion.

Possible improvements on current methods of treating diseased children offer a wide field for discussion, wider even than would be afforded by a consideration of those things which might well be considered in an attempt to better pediatric diagnostic methods. For the term "treatment" must be taken to include not only curative measures, but prophylactic measures as well. Even though prophylaxis leads far afield into studies of nutrition, ante-natal hygiene, personal hygiene, school hygiene, recreational hygiene, and to an understanding of many other aspects of public health.

The questions that arise out of the growing lay interests in preventive pediatrics might well occupy this society through many hours of its sessions, for in such are bound up much that is momentous for the future of our profession. These problems and their possible solutions are so many and so revolutionary in their implications that the present offers occasion to do no more than merely to indicate a few of them. Certain it is, however, that the answer to the queries inherent in the title of this paper would be incomplete if it did not point out that one of the general practitioner's greatest contribution to pediatric improvement must come through the organization of a service of information, advice and education to parents, designed to keep the children of the community in health. Such a service must begin by instructing the mother about her unborn baby. Later during the child's infancy it will be continued, and it will insist on properly supervised and adequate breast feeding when this is possible, or, in the event of a failure of the breast secretion, upon a well-guided course of artificial feeding. Already, such endeavors as these are enlisting the sympathy and effort of many physicians, but such a service must go further. Oversight of the nutrition and of the personal hygiene of the runabout child, should be a duty added to the many others under which the general practitioner staggers, and, at this point, even, he must not halt for the individual well-being of the school child, and the conservation of the adolescent's mental and physical health are essentially medical problems to be solved by the physician in general practice.

If we maintain our leadership in matters of health, we must be prepared to organize as part of our practice health services on some basis of proper remuneration, for, whether we like it or not, service must be given and leadership of the fast-growing health movement must be seized, otherwise not only will we fail in our duty, but we will lose the confidence and respect of our communities; a confidence and respect which has come to us as an inheritance from a long line of devoted general practitioners. It is for us to earn and to hold a continuance of this confidence and respect. Although only the medically trained can hope to accomplish results of real value, lay organizations, some of them hostile to our profession, already are reaching out to do much of the work. No matter how we as individuals view it, the movement for general health education is here, and it is here to stay.

The neurotics of the future are being trained today, trained by mothers, grandmothers and nurses, whose mistaken efforts to be kind often develop egocentricity and willfulness in their charges, and the physician who knows how suggestible children are, and who is aware of their tendency to negativism and egocentricity has to counteract this training, and to instruct parents how to treat their children so that they shall not grow up neurotic. To persuade mother or auntie or any other doting relative that it is kinder to keep an adored youngster out of the limelight, away from the center of the stage, and to revive in practice the old adage, "Children should be seen and not heard," will demand all that any man has of fortitude and patience.

No more important contribution to Pediatrics has been made than that which follows from the pioneering of Howland and Marriott on the importance of maintaining a normal fluid balance in the young child's body. The recognition of the urgency of the need for rapidly restoring fluid to compensate that lost from the tissues has been followed by a new emphasis on the value of the subcutaneous, intravenous, and intraperitoneal routes, for the injection of sterile normal saline solutions. Of these routes, the intraperitoneal is usually preferred unless peritonitis, or abdominal distension complicates the clinical picture. When the peritoneal route is chosen, it must first be determined that both the bladder and the stomach are empty, and that intra-abdominal disease is absent. The fluid may be injected by gravity or from a Luer syringe. It is important that the needle used shall have a short bevel (2 mm.). The tissues of the abdominal wall are seized about an inch below the umbilicus, between the thumb and fingers of the left hand. The needle is passed through that part of the abdominal wall which is included in the grasp of the digits. In this way the passage of the needle is guided, and the underlying viscera are protected. Once the needle is through the wall, the shank is depressed till it lies almost parallel to the skin, and it is then thrust gently upward. The shank is then connected, and the fluid flowing slowly is allowed to enter from either the gravity glass or from the Luer. Pains must be taken to maintain the temperature of the fluid at 100 to 101 degrees, for the fluid, as it flows from the

* Read before the Fifty-first Annual Meeting of the Medical Society, State of California, Yosemite Valley, May, 1922.

needle-point, will be about 3 degrees colder than it is while in the container. Certainly a mastery of this technique and a wider use of this method by the general practitioners will tend to improve the treatment of disease in children.

The more frequent employment of glucose in intravenous injection, another desirable measure too little used, also offers the profession opportunity to improve its therapeutic methods. The great value of this measure rests upon the fact that under the stress of non-diabetic ketonuria, of the acidosis, which complicates vomiting and diarrhœa, during general infections and in most toxæmias, the glycogen reserve of the body becomes depleted and the reserve can be augmented, and to some degree restored by the intravenous use of glucose. The method has also the advantage that glucose in hypertonic solutions of from 10 to 15 per cent draws fluids from the tissues into the blood stream, and also acts as a diuretic. Unfortunately, we have been taught to fear the use of sugars. Nevertheless, the only way to maintain the glycogen reserve in the presence of acidosis is to give glucose or lactose solution freely by mouth. Often if quantities of such a sugar solution, well diluted, are given persistently, and in spite of the emesis, vomiting will be promptly aborted and checked. In persistent or in neglected cases of cyclical vomiting, when sugar by mouth alone is ineffective, the intravenous injection of 10 per cent glucose solution is life-saving, and the intraperitoneal injection of normal saline solution is an invaluable adjunct.

The general practitioner who is earnestly endeavoring to improve the treatment of children, would make no mistake if he resorted to a more extensive use of hydrotherapy. Packs of mustard, hot, tepid or cold—full packs or one-half packs—and baths will really do all that antipyretic drugs are vainly expected to accomplish.

If an increasing knowledge of hydrotherapeutic methods led to the abandonment of many antipyretic drugs in pediatric practice, much would be accomplished for the benefit of sick children. There would certainly be a great advantage in the development of an attitude of distrust for too much drug therapy in general. A determination to use drugs only where specifically indicated, under circumstances in which the physiological action of the drug makes it a logical weapon against the pathological process which is causing distress, would be the mark of much progress.

The practitioner who is able to escape the overuse particularly of laxative and purgative drugs, and who can attain the results he seeks by wise regulation of diet, regime, exercise and habit training, and hydrotherapy, certainly is contributing to better the treatment of disease in children. So, also, is that man who himself has learned and who has taught the nurses and the mothers of his patients that a vomiting child who is constipated is to have its bowels moved by enema only, that under no circumstances shall purgative drugs be given it, for fear that an obstruction of the gut has occurred. The admonition may be of use but rarely, but the general application of such a rule might have saved some of the babies who have died after intussusception or volvulus or the strangulation of a hernia.

The unnecessary mortality rate in diphtheria, dependent upon delayed diagnosis or upon inadequate dosage of antitoxin, is a constant reminder that in this field, at least, there is opportunity to improve diagnosis and treatment. Here clinical signs may be misleading and the laboratory a fallable aid, but for the child's sake, let it never be forgotten that it is harmless to give antitoxin unneeded, and murder to omit when it is needed. The practitioner who knows what Park and his associates have done, and who practices to elucidate the problems of treatment and of prophylactic in diphtheria that they have taught, is surely contributing much to the betterment of medicine, especially if he has come to use antitoxin by intramuscular injection rather than by subcutaneous. He ought also to have in mind that intravenous injection can possibly be used in the treatment of neglected or of very toxic cases. When he does find it necessary to use the vein for injection of antitoxin, he must scrupulously observe the technique of desensitization.

A wider appreciation of the value of antidysentery serum would be an advantage to many infected children, if it led to more frequent use by intravenous injection in those patients who have become deeply intoxicated. The more frequent use of polyvalent anti-streptococcus serum in those patients whose blood stream has revealed infection by blood culture, might not accord with the views of all authorities, but well diluted in hypertonic glucose saline, given slowly, this serum will often prove to be life-saving; under the same pathological condition, the additional use of transfusion by the direct or indirect method in these septic cases amplifies the possibilities for good. A more frequent resort to transfusion, always with due regard to its proper technique, offers the physician opportunity to save lives. Even the intramuscular injection of whole blood, simple as it is, is a neglected procedure in spite of the fact first demonstrated by Oscar Schloss that it checks idiopathic hemorrhage of the new-born with promptness and certainty. It is hardly less valuable as an adjunct to dietetic measures in the treatment of infantile anæmia and nutrition.

A glance over the domain of dietetics, nutrition, and therapeutics, reveals other fields that might reward the physician's closer cultivation. Vitamines are flung at us from every angle until we are, as the English say, "quite fed up on them," and with all the pother, we have learned just what our forefathers knew and what every physician knows, that is, that fat and green vegetables and the parts of grain next the pericarp are essential to complete nutrition. It is not to be wondered at that many physicians in general have been turned away from interest in foods and feeding by pesky percentages and the curse of calories wished upon them by the higher-browed mathematicians in signed and cosigned pages of

formulæ. Certainly, when the United States Bureau of Child Hygiene send broadcast such pernicious misinformation as is embodied in the statement that a child of any age who has no more than four teeth should be restricted to a fluid diet, it is time that medical men awakened to a deeper interest in nutritional and dietetic problems. Such awakened interest is needed to enable the profession to combat fallacies of this sort, and if the interest is gained the reward will be an added power for good work in the prevention of disease.

A simple catalogue of possible improvements in the treatment of sick children could easily run beyond the bounds of this paper, and hardly do more than touch the limits of the subject. To mention all of the possible ways and means that might aid us to improve the diagnoses of those children's diseases which so often trick us into error might well fill a volume.

Primarily, however, it is true that the better diagnosis will be made by those who remember that children, as children, possess positive anatomical and physiological peculiarities. Failure to recognize this fact leads to improper treatment. These essential peculiarities impose a special routine for the physical examination of children, quite unlike that best adapted to adults.

John Thompson, one of the wisest of those who write about sick children, has pointed out that in the examination of a child, the best information is not to be had by exploring one physiological system after another as is normally done in the investigation of adult ills. Much more valuable is a procedure based upon the use of one method of physical diagnosis after another. The most important of these methods is proper inspection.

Many a regret would have been spared had it never been forgotten that a child should always be completely undressed for a physical examination, but the child who is beyond infancy should not have its clothes taken off in the presence of the doctor. If the wilful, egocentric baby of from one to three years who struggles and screams at the slightest provocation is undressed in a room apart from the physician, and wrapped in a blanket or gown that opens down the back, he can be examined more easily. He can be brought in to the examining room on the mother's or nurse's shoulders, and with his back toward the doctor, sometimes before he is even aware of the physician's presence, the head, ears, skull, back, buttocks and legs can be inspected.

The physiological peculiarities of the well child are paralleled by a series of marked and equally significant pathological alterations in the case of those who are ill. These alterations bring about expressions of disease, and disease peculiar to children. The same sorts of pathological agents may produce clinical pictures in sick children different from those they bring about in adults; so different, in fact, that sometimes it is hard to believe the causes of the sickness identical. Then, too, certain maladies are prone to attack children, and others quite commonly found among adult patients are so rare in early life as to be curiosities. Acute rheumatism, for instance, is almost unheard of in a child younger than three years, yet scurvy, common in the second and third years of life, has been mistakenly called rheumatism.

In examination of the infant, complete and searching inspection is more richly rewarded than is any other single means of eliciting information. The facts derived from inspection taken in the light of the history of the patient's indisposition, and with a due consideration of the natural history of disease in childhood often suffice for diagnosis, although other indicated physical and laboratory means must not be neglected. It is certainly no exaggeration to say that diagnosis could be bettered if every one who deals with sick children would devote more time to a study of the possibilities of inspection.

The position in which the child carries the head may reveal information of much value. If it is retracted, it at once suggests postcervical adenitis, which may be the result of an infected adenoid, or be a part of a retropharyngeal glandular infection, or, less frequently, it may signify a meningitis. Held to one side, the idea of an immobile torticollis or of the unusually occurring cerebellar tumor may be brought to the mind of the observer, and give him a lead. In a like manner, the child flushed with fever who protects one side of his head with the hand or by pressure against the mother's shoulder, will afford a clue which makes thorough search of the ears and mastoid imperative.

Amount and quality of the hair at once mark the state of the child's nutrition and, together with the character of the bony development in the frontal and parietal regions, give information which will reveal or exclude rickets. A look at the occipital scalp of a bed-ridden child, who has been the victim of an unexplained fever with distress, sometimes reveals the cause of the pyrexia to be a furuncle hidden in the hair, which may have been overlooked because the physician himself has not sooner raised the back of the child's head from the pillow for scrutiny.

The bulging fontanelle, the separated sutures and the peculiar eye appearance of the hydrocephalic are at once apparent, and not less noticeable is the wedge-shaped insufficient vertex of the microcephalic with the blank, staring faces beneath it.

The expression of the child's face usually reveals at once whether the mother's anxieties are justified by the real sickness, or unjustified and merely the result of her ignorance and the child's naughtiness. The anxious-looking baby with a flushed face, an obliquely held eyebrow, a slightly open mouth, the fluttering wing of whose nostrils suggest pulmonary involvement, demands prompt and thorough chest examination.

The puffy face that goes with renal disease is distinctive, but puffiness may also mark giant urticaria. Quite diagnostic is the trismic smile,

earliest sign of tetanus, and equally informing, the weary, aged faces that develop in the course of a protracted disease such as chronic diarrhœa, peritonitis, empyema, and the low-grade osteomyelitic infections. Nor is the dried-out aspect of the baby who is subject to an acute attack of vomiting and diarrhœa, open-eyed, staring, with depressed fontanelle, and hollowed cheeks to be mistaken any more than the peculiar look of sage thoughtfulness, with shut eyes, slightly retracted head, and close-clenched jaws that mark the chronic meningitic. These are almost as recognizable as the open-mouthed appearance of nasal obstruction. One important revelation that sometimes rewards inspection is the discovery of an edema about the mastoid region. When one ear is forced away from its normal relation to the scalp and head, and, when looked at from behind, occupies a position quite unlike that of its fellow, underlying mastoid-cell infection may be inferred, although it must never be forgotten that the same sign may result from a single abscess of the postauricular glands. Such an abscess is a not infrequent complication in the presence of abrasions of an unclean, it may be a pediculous scalp. The swelling in front of the ear overlying the upper part of the parotid and the zygoma is as important an index of mastoid involvement as bulging behind the ear, and such swellings mean that there is an imperative need for surgery.

A look at the torso of the naked child may be equally informing. It is astonishing how easily even slight degrees of difference in the chest movements of little children may be discovered, but the light must be bright; it must fall equally and unshadowed, while the observer should stand at some distance behind the patient. A scrutiny of the front of the chest to note the position of the apex beat, percussion and radiography in order will confirm the suspicion that fluid is in the pleura or reveal a consolidation, unless some rarity such as sarcoma is complicating the findings. Inspection that reveals the slightest limitation in the flexibility of the spine justifies suspicion of spinal caries. The usual child is a wriggling, restless creation, and its flexible spine is invariably making some twist or other. A history of pain in the belly, or of pain developed by jarring, makes it doubly probable that early Potts disease is present. This malady brings with its full development such hideous crippling that the physician alert for his patient's interest must keep its possibility always in mind, because often, if diagnosis is made early and proper treatment is promptly adopted, the disease can be checked.

Through frequent and careful oversight of the spines of the children who come to him, the general practitioner may discover curvatures and postural defects, and by measures of corrective gymnastics overcome such defects while they are easy of correction. It is doubtful if any single division of pediatric endeavor will better reward the general practitioner than a study of the application and principles of corrective and prophylactic gymnastics, a study which will enable him to restore normal posture and to improve the nutrition of children.

It would pass the bounds of this paper to catalogue all that is to be learned from inspection of the extremities, especially of the hands, or from simple observation of the abdomen.

There are certain children's diseases readily to be recognized because the appearance, attitude and expression of the patient testifies to their presence. Of these, two, infantile scurvy and mongolism, sometimes reach the hospital unidentified or misdiagnosed. In appearance, the sufferers from scurvy are pale, irritable, with pain expressed in every feature. They lie in a state of pseudoparalysis, inert, with the thighs drawn up, guarding one or both legs, or perhaps an arm from movement or interference. Perhaps with bruises here and there on the skin, sometimes with a one-sided proptosis, the result of a hemorrhage, which has invaded the subperiosteal region of one orbit. Other subperiosteal hemorrhages usually of the long bones, but especially of the femurs, may be present and palpable. When there are erupted teeth or teeth about to erupt, the gums are spongy, swollen, and ecchymotic; too often sloughs may be found, sequels of a mistaken resort to that ancient barbarity, the gum lancet. Such a clinical picture is pathognomonic. Not less so is the typical history of an infant too long fed and too exclusively fed on cooked food, usually boiled, condensed, commercially pasteurized or dried milk, or on some proprietary preparation without the compensation of vitamine-bearing substance such as orange juice, green vegetables, and cod liver oil. For a long time the little patient has been pale, irritable, capricious in appetite, resentful of even the gentlest handling. As the days and weeks passed, such symptoms increased in intensity, and it was noticed that the child bruised easily, and one day developed swelling about one or another joint. The baby later fell into the condition of pseudopalsy, which brought the parents to their doctor for advice. No other disease of childhood much resembles this quite common malady, and yet, not infrequently, it is mistaken for rheumatism, an affection so rare in early childhood that it can truthfully be said not to attack before the third year. Sometimes these infants fall into the hands of osteopaths and chiropractors, whose manipulations are especially torturing to the tender flesh of the scorbutic.

Mongolism, a condition that comes with obvious mental deficiency, deformed head, ears, and nose, chubby hands and feet, seems often to be confused with cretinism, a physical state in which these peculiarities are also to be found, but the slant eye, smooth, fine skin and fine, sparse hair, and extreme hypotonicity of the mongol, mark its condition as one apart from cretinism. For, in cretinism, the hair is scant, it is true, but coarse. The skin dry and rough, the eyes are normal in shape and position, and hypotonicity is not a feature. A cretin shows besides these features its chubby hands, its myxedema, the aged expression of its face, and peculiar distribution of its sub-

cutaneous fat pads. The subnormal temperature, and the extreme constipation of the child are added points that distinguish the hypothyroid patient, and indicate the need for thyroid feeding.

Quite often, pyelocystitis, commonest cause of fever and malaise in girl-babies is overlooked. Doubtless, this oversight comes because its great prevalence between the eighteenth and thirtieth months of life is forgotten, and perhaps, too, because it is thought a difficult matter to obtain urine samples from young girl patients. It is always possible to catheterize a girl child, and if scrupulous surgical cleanliness is insisted upon no harm can follow. W. P. Lucas has made it possible to obtain urine from girl-babies as easily as from boys, by his discovery that the ordinary cheap glass bird-bath to be found on canary cages is a utensil perfectly adaptable as a urine collector. Such a glass bath can be sterilized, and then be applied to the vulva and fastened in place by the pressure of the pinned diaper. The routine use of such a device will make it possible always to examine the urine of girl-babies, and to render the diagnosis of urinary disease generally possible. For collecting the urine of a boy, nothing is better than a rubber glove. The boy's genitals can be included within the wrist of the glove, which is to be fastened in place by adhesive plaster.

Another rather common disease, hypertrophic pyloric stenosis is a disorder with a distinctive clinical picture, yet it sometimes eludes diagnosis, a misfortune for its victim, for when diagnosed early the treatment by dietetic or operative measures is almost uniformly successful. If every physician would make it a rule to make thorough inspection of the complete, naked bodies of his baby patients, no instance of pyloric stenosis could escape detection, especially if in addition the inspection of the infant's abdomen were made while the child was nursing. Under these circumstances the very characteristic epigastric wave produced by the contracting stomach is easily seen as it passes across the upper abdomen, running at the rate of about twenty contractions to the minute, and equally visible and as striking will be the peculiar, huge, bulging, epigastric area in its contrast with the narrow flattened hypogastric region. Such findings in the case of a constipated baby who began to vomit between the second and fifth weeks of its life, and who continues to vomit persistently and explosively, who passes little urine and shows the results of fluid loss should be enough to rescue the little one from protracted attempts to find a suitable diet. One diet only, the thick, gruel milk feeding holds any promise of help for such a patient. If this fails to check vomiting and to initiate gain within a few days, then a recourse to the Fredet muscle-splitting operation is indicated. With proper surgical technique, provided the patient is not already moribund, this operation is almost certain to be crowned with success.

A more general realization that spastic paraplegia and spasticity, with mental defect, many times are referable to injuries from too prolonged labor rather than from damage by the forceps which terminated the labor, or to the blood dyscrasis which it is now popular to blame, and that earlier resort to forceps, or, if need be, to Cæsarian section, might be productive of much good to childhood were it more encouraged among those general practitioners whose work includes obstetrics.

It may be said that the practitioner or specialist can improve the diagnosis and the treatment of disease in children in just the same way that he can improve the diagnosis and treatment in any other department of his practice by keeping himself well informed about the bases of medicine, as well as about the peculiarities of the special work. It may be that the fate of many a child would be bettered if we were more critical in the selection of patients for tonsillectomy. The fact that brilliant results follow the removal of diseased or obstructing tonsils is no warrant for the idea that every visible tonsil is a criminal to be forcibly guillotined or guilefully snared to its destruction, and the disillusionment of physician and parent would be less were it more clearly recognized that there are other common causes of persistent mouth breathing than adenoid growths, and that the mere removal of these when present will not make it possible for the child with a high arched palate, deviated septum, enlarged turbinates and anterior rhinitis to breathe through its nose. For a remedy of the high-arched palate we must turn to the orthodontist. The changes in the anterior nares demand long, patient, and painstaking treatment after the removal of the tonsils and adenoid. Not only this, but the general condition of the patient must be improved. Long before tonsillectomy came into vogue, Iodide of Iron was a potent remedy which, together with proper feeding and hygiene, put many a child in condition to fight off the ill-effects of enlarged tonsils or infected adenoids, and used in the same way, it still is potent as an adjunct to the local measures indicated after the removal of an adenoid and tonsils.

Not only for orthodontic aid do we need to call on the dentist. Decay in deciduous teeth most often comes first to the attention of the attending physician. To him also comes the convincing evidence that the care and filling of this early set of teeth is one of the most fruitful prophylactic measures at his command. Unfortunately, he will have to struggle not only to convince indifferent parents, but to overcome the active opposition of dentists, many of whom are unwilling to give their time and detailed work to the preservation of temporary teeth. Fortunately, the dentists of the present generation are coming to their task with a training that makes them able and willing to help the physician in this matter.

Diseased tonsils, bad teeth, nutritional disturbances, and faults of hygiene make up a list to plague those of us who deal with children, but tragedy rarely attends among these, but there are afflictions swift and terrible in their onset for which we must ever be on the watch lest death

catch us unawares and carry off our patient before we sense the danger. Every sick child should be to us a possible victim of these deadly things until we have excluded them one and all—diphtheria, bowel obstruction, appendicitis, especially intussusceptive; mastoiditis, retropharyngeal abscess, early Potts disease, dysentery, typhoid—fortunately, there are not so many. All of them we should have in mind, and their earliest known signs and symptoms should be as familiar to us as the letters of our alphabet. Not only so, but in our reading we ought always to be especially on the lookout for new information about these deadly enemies of childhood.

For the diseases of children this can best be done by knowing well how to refer to late editions of standard books, and a good journal or two such as the American Journal of Diseases of Children, and the "Archives of Pediatrics" should find a place on every practitioner's desk. The perusal of such journals and books kept handy for ready reference will elucidate the peculiarities of physiology and pathology which make the manifestations of disease in juvenile patients so perplexing, especially to those who approach children as if they were adults with an adult psychology and adult types of pathological disturbances. The knowledge so gained will emphasize the need for special methods of attacking problems of physical diagnosis and for special information about the peculiar natural history of certain common diseases as they affect children. Moreover, such a plan will clear many of the problems of infantile nutrition and bring a juster appreciation of the influence of personal and school hygiene.

240 Stockton Street.

OSTEOPATHS USE A PLUMB-LINE AND SPIRIT LEVEL TO FIND A PERFECT SPINE

(Quoted from the San Francisco Examiner of Sunday, April 2, 1922):

"We feel sure that there is no such thing as a perfect back in existence. Almost every person can remember having at least one fall or twist or accident that at some time or other wrenched or twisted their spine so that they were laid up or uncomfortable for a day or more. These are all recorded in the spine. . . . The quite astounding fact seems to be that brunettes have better backbones than blondes. That is, the brunette average up to date has been far ahead of the blonde average."

BULLETINS OF THE AMERICAN MEDICAL ASSOCIATION

All physicians interested in the activities of the national organization, the House of Delegates or Council on Medical Education and Hospitals and other official bodies of the A. M. A., should be subscribers to the Bulletin of the American Medical Association. The proceedings of the conference of national officers and state secretaries, held in Chicago last November, will be found in recent numbers of this Bulletin. The annual subscription to the Bulletin is 50 cents, and letters should be addressed to N. P. Colwell, M. D., Secretary of the Council on Medical Education and Hospitals, 535 North Dearborn street, Chicago.

COMMON PARASITIC DERMATOSES IN SOUTHERN CALIFORNIA *

By MOSES SCHOLTZ, M. D., Los Angeles.

It is my purpose to call attention to the great prevalence of certain parasitic dermatoses in Southern California. Examination of private and clinical records convinces me that parasitic dermatoses due to ectogenous infection make up not less than 29 per cent of the total number of skin diseases.

I have deliberately omitted all rare and spectacular dermatoses, such as leprosy, granuloma coccidioides, actinomycosis, and lupus, and have limited my remarks to parasitic dermatoses that the family physician is called upon to treat in his daily practice.

This reduces the consideration to skin lesions caused by streptococci-streptodermias; those caused by staphylococci — (staphylodermias); tinea and scabies.

That these four parasitic dermatoses make up not less than 29 per cent of skin diseases merits serious attention by physicians.

It is the purpose of this paper to present these parasitic dermatoses, as they have occurred in clinical work, to review their most striking characteristics and to outline briefly their diagnosis and treatment.

Streptodermias — The most widespread of all parasitic dermatoses are those due to streptococcic infections (streptodermias). It is surprising how little streptodermic lesions are known to the general profession. Impetigo contagiosa is better known, and yet it constitutes only a very small minority of streptodermias.

There are quite a number of clinical forms of streptodermias of common occurrence. The list includes persistent intertriginous patches, cracks or fissures in the corners of the mouth—so called perleche, and similar lesions in the retro-auricular, naso-labial, axillary and inguinal folds. Another rather common form is the inflammatory patchy form streptodermatitis. It occurs in single or multiple patches, most often on the limbs or the trunk of the body and, if left untreated, may last many months and even years.

These lesions usually diagnosed as plain chronic eczema, and treated with bland, indifferent ointments, such as zinc oxide, boric ointments, and Lassar paste. Occasionally they are regarded as syphilitic lesions with which they have a considerable resemblance.

The clinical features of the various types of streptodermatas are sufficiently characteristic to make clinical diagnosis secure. The principal features are: sharply defined circinate borders of deep dark red color or occasionally suggesting violaceous. The lesions feel soft, with a soft, thin crusting. Itching is slight or absent; infiltration is never as deep as in syphilis, and the surface is never harsh and rough as in plain eczema. An important differential feature is that common

* Read before the Southern California Medical Society at the San Diego Meeting, April 7, 1922.

eczema always has ill-defined borders and diffuse vague outline. Whenever any part or the whole eczematous patch begins to show sharply defined and circinate borders it is a safe indication that a secondary infection of streptococci, staphylococci or seborrhoic contagium is present.

The treatment of the streptodermias is very simple. Washing and removing of all crusts and deposits is the first and the most important step. Mercury amoniate ointment 2-5 per cent acts as a specific in almost all patients. Exceptionally it fails, and then sulfur and salycilic acid of the same strength in ointment is indicated. In cases of streptodermatitis with any amount of infiltration due to secondary eczematization I prefer to use crude coal tar ½ per cent in Lassar paste. In generalized and extensive cases ultra-violet light exposures are a most powerful and elegant method of treatment.

Staphylodermias—As a diagnostic problem staphylodermias are much simpler than streptodermias. In pure cultures staphylococci are apt to produce follicular lesions, such as folliculitis, furuncles and carbuncles.

Sycosis staphylogenes—Among various staphylodermias sycosis deserves special mention because of its chronicity, rebelliousness to treatment and the great distress caused by it. Diagnosis should not be difficult and should be made essentially on the presence of discrete or confluent follicular abscesses limited to the hairy part of the face. From a therapeutic point of view it is important to remember that in sycosis, as in tinea capitis, the parasite nests at the bottom of the hair root; hence, no treatment short of epilation can give lasting results. The painful method of pulling hairs one by one with the forceps should be superseded by X-ray epilation. After epilation is effected in sycosis, antiseptic ointments and washes are used before the new hair comes in. With the hair follicles open, antiseptic local applications easily penetrate to the seat of infection and effect a lasting cure. Staphylococcic vaccines, autogenous or stock made, are efficient and strongly indicated in furunculosis and carbunculosis, but they are very uncertain and unreliable in sycosis.

Tinea—In its various forms tinea occupies a place among parasitic dermatoses second only to streptodermias. The prevalent notion that the so-called ringworm presents always ring-like lesions with a clearing center and active edges is erroneous. Only a very small minority of tinea lesions, probably those due to a certain strain of fungus, is of ring-like shape. Diagnosis of tinea of the body is made clinically on the presence of sharply defined borders—dry, scaly deposit on an inflammatory or non-inflammatory base, superficial slight infiltration, or none at all, round, circinate or segmented shape and extension by continuity. While the presence of the fungus by microscopic examination constitutes a decisive test, it is necessary only in the exceptional cases. In the overwhelming majority of cases a clinical diagnosis is possible. In tinea of the scalp the additional clinical evidence is the presence of patchy alopecia hair stumps of dull, dusty, and lifeless appearance, together with weakness and brittleness of the hair. Tinea of the scalp is not more prevalent than other types, but from a therapeutic and social point of view it presents a grave problem because it affects mainly children of the school age and often keeps them out of school for many weeks and months. The choice of antiparasitic application is of little importance; sulfur, salycilic acid, mercury, phenol, all clear up and improve the surface of the diseased area. The best application is 3-5 per cent solution of chrysarobin in traumaticin. The reason for the stubborness and tendency to relapses of tinea of the scalp is that none of the local applications reach the bottom of the hair follicles while the hair is in. For this reason the chronic stubborn generalized cases of tinea of the scalp can be radically cured only by X-ray epilation. The hair grows again from two to four months. After epilation antiseptic applications are kept up on the bare scalp to destroy the rest of the fungi. Tinea cruris is the next in frequency. The interesting feature of this type is that, while it occurs like its counterpart on the hairy parts, the hair, unlike those of the scalp, remains unaffected. This is because the fungus in these places remains on the surface and does not penetrate inside of the hair follicle. For this reason tinea cruris can be cured with various antiparasitic applications without epilation. For the same reason tinea cruris does not produce patchy alopecia and does not alter the vitality and the appearance of the hair. However, the treatment of tinea cruris presents its own difficulties. The first one is the extreme tenderness of the skin of the genito-crural region. It is rather difficult to select a strength of antiparasitic application sufficient to destroy the fungi and yet not strong enough to irritate the skin. It is quite common to see patients with tinea cruris with the skin acutely inflamed or actually blistered by the local medication. The most efficient and elegant treatment of tinea cruris is radiation with ultra-violet rays from a good quartz lamp. The specific virtue of ultra-violet rays in these cases is in an even diffusion and penetration of the rays in all the irregular lesions as well as in covering a large area beyond the visible borders of the affected area. With daily exposures to quartz lamp, antiparasitic applications can be dispensed with. The reaction from the radiations should be brought to a distinct erythema and exfoliation. Blistering is not advisable, though it does no harm.

Tinea axillae is much rarer than tinea cruris. The treatment of both conditions is identical.

Tinea of the toes has been lately subjected to considerable study, and its clinical types are quite well established. Bacteriologically, it has been identified as being caused by an Epidermophyton. The most common location is between the toes and the soles. Clinically, it resembles very closely ordinary intertrigo, vesicular or squamous eczema, pompholyx, and pus infection. Accurate diagnosis can be made only by bacteriologic methods. But in the majority of cases it can be recognized clini

cally, or at least suspected by lesions showing well-defined circinate margins, epidermal collarettes, and spreading by extension. The treatment is the same as in other types.

Scabies—Scabies seems to be so simple and so well defined as not to admit of errors or confusion in diagnosis. Yet it is surprising how many cases of scabies remain unrecognized. There are several sources of errors. The first is the prevalent notion that scabies is a disease of slums and that it does not occur in good society. Many physicians on that account are prone to overlook scabies in their well-to-do patients. I have seen almost as many cases of scabies in private practice as in the clinics. Another source of error is due to mild or abortive cases of scabies which are usually seen in cleanly people and families. In these cases lesions are very insignificant and may consist of a few widely scattered top-scratched papules, presenting very little resemblance to well-developed cases of scabies. Such cases may be mistaken for eczema, and in children they are frequently mistaken for a food rash. The true nature of these cases can be readily identified by the following clinical features: the papules are not inflammatory, top scratched and hemorrhagic. They are discrete, and show no tendency to run together into ill-defined inflammatory areas, as in eczema. They are located preferentially on flexor surfaces on widely scattered parts of the body. The burrows may and may not be seen. Secondary eczema and impetigino-like lesions are particularly common in children and individuals with a tender and irritable skin. These secondary lesions may dominate the clinical picture to such extent as to mask completely the underlying primary condition of scabies.

The treatment of scabies is simple enough to be standardized. Sulfur 5-10 per cent alone or in combination with tar and green soap, in the form of Wilkinson ointment, is a specific. Two points, however, should be kept in mind to avoid mistakes. The first is to guard against sulfur dermatitis or sensitive skins by stopping treatment at a proper time. The second is a possibility of the persistent complaint of itching in neurotic individuals after an apparent clinical cure.

CONCLUSIONS

Ectogenous parasitic dermatoses are very common in Southern California. They make up about 30 per cent of the total number of skin diseases.

The most widespread in the order of frequency are streptodermias, tinea, scabies, and staphylodermias.

A more thorough isolation of skin lesions caused by streptococci, staphylococci, tineae, and scabies should be enforced in schools and in homes.

A sanitary inspection of domestic animals, particularly dogs and cats, in all homes where cases of tinea are reported, is highly desirable, as these animals seem to be the main agencies in spreading tinea.

Cases of tinea and scabies should be reportable.

FACTORS CONTRIBUTING TO SUCCESS OR FAILURE IN GROUP MEDICINE

By E. V. FREDERICK, M. D., Reno, Nevada

Why do medical men attempting to work together in a group sometimes fail? William Mercur of Pittsburgh in a personal communication says:

"I have been investigating the subject of group medicine for the last ten years and my report is based on the forty-three failures out of the forty-five groups I have investigated. My opinion as to the causes of failure are: (a) Based on wrong ideals; (b) Improper selection of staff; (c) Organization defects; (d) Use of voluntary workers (applying to charity clinics)."

The basic thought in medical ideals is better service to the public. Group work aims to accomplish this by greater accuracy in diagnosis; by eliminating errors; by checking up and minimizing the weaknesses and peculiarities of the individual diagnostician; by massing an equipment, the most important part of which is brains; by utilizing the services of technicians and lay assistants and mechanical and laboratory equipment; and by specialization in treatment.

Group practice also aims to provide better service to the public through a scientific handling of the rest and fatigue of the staff, thereby giving them time for reading, recreation, or post-graduate study; and by unloading petty and aggravating detail from busy highly trained specialists to lay helpers trained to handle these matters.

Wrong ideals are primarily responsible for the failure of some groups. Some groups are formed primarily for financial gain, which may be secured by a number of well known activities based upon business ethics but out of harmony with the highest ideals of the medical profession. Groups of this character usually fail because they fail to secure the confidence and respect of their colleagues, without which neither the individual nor the group can progress far; and they also sooner or later lose the confidence of the public.

False ambition and egotism invite failure. Some physicians have the mistaken idea that a group of general practitioners makes a clinic; that a general practitioner joining a group becomes a specialist, entitled to a specialist's fees overnight, and what was an ordinary opinion under one circumstance becomes the opinion of a specialist under another and worthy of an increased fee.

Improper selection of a staff or ignorance of the qualifications and type of men required for successful group work is another chief cause of failure.

Excluding the groups formed around one prominent man by his assistants; by a father and his several sons, all members of the profession; the partnerships of brothers with a paid understaff, and similar organizations, how can a number of ordinary medical men work together successfully to the benefit of their patients and themselves without inviting failure?

The primary difficulty in forming a group of this character is that no one wishes to admit the leadership of another, and the attempt frequently is made to function with all the staff equal in

management. Any such group is certainly doomed to failure because they are attempting the impossible. A directing head is absolutely necessary if success is to follow and to insure that the individual labors of each member of the group shall be utilized in the attainment of common results. This one-man control, although essential, also has its disadvantages and may lead to abuses of authority. The form of organization that is practical and just is one in which the entire responsibility is placed on one person of the group with provision for certain checks by which his work is susceptible to review by other members of the organization.

The greatest problem in any group organization is to find a directing head. Such a leader must fulfill the following requirements:

(a) He must have a personality which will not antagonize his equals and which his superiors, if he has any, will respect and his inferiors honor.

(b) He must have a wide knowledge of men and women and how to organize, energize and inspire those who are his co-workers.

(c) He must be trained in the principles of scientific management so that peak loads will be avoided in the group's work.

(d) He must be well acquainted with methods of finance to carry the organization over the bumps which are sure to arise.

(e) He must have an expert knowledge of the "clinic" system of clinical routing and "check-up" system of diagnosis and interdepartmental consultation, so that he can guide the internal machinery of the staff.

(f) He must be fairly well grounded in laboratory work so that he can veto unnecessary foibles which increase overhead beyond income, or so that he can introduce into routine procedure valuable methods which will bring income above overhead.

(g) He must have knowledge of the method of keeping an up-to-date "Procedure System."

A MANAGER WITHOUT ALL THIS KNOWLEDGE IS A BLIND MAN LEADING THE BLIND AND THE GROUP IS SURE TO END IN FAILURE

Even with a perfect directing head and a number of specialists the professional staff may still fail to function as a group because of lack of special training for group work or unwillingness or inability to overcome individual habits. Successful group work is a specialty in itself.

Causes of individual failure are:

(a) Inability of old dogs to learn new tricks or unlearn selfish habits.

(b) Inability or unwillingness of the individual to change from a memory system of records and case histories to an extensive paper system with considerable time-consuming detail.

(c) Failure to properly co-operate with other members of the group in the production of "team work."

As Kipling says:

"It ain't the guns nor armaments
Nor the funds that they can pay,
But the close co-operation
That makes them win the day.
It ain't the individual
Nor the army as a whole,
But the everlasting team work
Of every bloomin' soul."

(d) Desire of the individual to push his fads and foibles.

(e) Ignorance of "Clinic" diagnostic routing and laboratory "check-up" systems and inability to reduce all data to complete diagnoses. In this regard Louis Wilson says: "Unfortunately, it is true that the average training of the clinician of today is sadly defective on the laboratory side. . . As a result, when there comes to him concerning a patient the data furnished, say, by a complete examination of the urine, by an examination of the blood, by an examination of the gastric contents, by an examination of the feces, by a fluoroscopic examination of the alimentary canal, by a bit of tissue clipped from one point, he is wholly unable to assimilate, to co-ordinate and to interpret the data obtained."

Having found a satisfactory directing head and a good team working medical staff, the next important item in group organization is the choice of the understaff and lay workers, as bookkeepers, secretaries and technicians.

Success in this respect requires careful thought in numbers, personalities and salaries that will not produce too high an overhead. Each one should be trained not only in their own line of work, but as an understudy of some one else, so that when one is ill or drops out, the work will still go on efficiently. Their work must be so arranged that all are busy during the day, and yet so that none are overworked. All assistants must be kept inspired and happy in their work.

The tripod on which any organization rests is management, policy and finance.

A group should have a managing board to fix policies; to check and stabilize the manager; to guarantee to the public the "morale" of the organization; to referee disagreements about finance or other difficulties between members of the staff.

Many groups fail because they have no defined policy. A policy ill defined or based on wrong ideals is as bad as none. The policy should be decided before organization is completed and before any money is spent on buildings or equipment.

Some of the common questions to be settled in determining the policy of a group are:

(a) To have a directing head or not. If so, what are his powers?

(b) To have a directing board or not. If so, what will be its powers?

(c) Will this board be composed of outside laymen or medical men within the group, or both?

(d) What types of practice are to be included?

(e) Is the group work to be limited to diagnosis, or include diagnosis and treatment?

(f) What attitude to be adopted toward venereal, neurotic, chronic and other special types of patients?

(g) To grow indefinitely or to an ideal size?

(h) To work for charity or to make the staff wealthy?

(i) What ideals and objects are to be striven for?

(j) What attitude toward other members of the medical profession?

(k) To be ethical, ultra-ethical or non-ethical?

(l) What relation toward the public, how to get and retain their patronage?

(m) What type of propaganda, education and advertising, if any?

(n) Promotion and direction of members of the staff; how made and by whom?

(o) Separation of members of staff for improper conduct, how arranged?

(p) What hospital connections to be established?

(q) To seek religious affiliations or not?

(r) What percentage of net income for charity, if any? How shall it be spent?

A crucial part of the policy is the settlement of the questions of finance.

How shall fees be arranged? How divided? How collected? What recompense for a member discharged? What recompense for a member retired for illness, long service or old age? Where will the money come from to cover loss during the first year or so or during hard times?

Many groups are started by one or two enthusiasts who gamble on the cost of building or equipment and trust to Providence that a policy bringing success will arrange itself by trial and experience. But, unfortunately, during one of these trials the corporate body dies before it gets the experience.

In group work friendship must be regarded as a bridge of straw. Only one tie can be relied on—cold cash. If this is unsatisfactory, all else will go to smash.

A fundamental principle in business, one which is difficult for doctors to grasp, must be remembered. The business and the individual are two separate and distinct entities even in private practice. The business employs the physician or surgeon and pays him a salary as manager of himself. He may also be bookkeeper and stenographer and what not. In group work the organization employs someone else to handle some details, while the doctor specializes on others.

Advertising is another important part of policy. Here I am getting on dangerous ground. But whether we like to face the fact or not, this rule is true—that the success or failure of a group depends on the superiority of its advertising. Please note the full significance of the word "superiority," not quantity but quality, which always must be of an ethical character.

A group advertises ethically:

(a) By the high qualifications of its staff, their social position and activities, and likewise of their families.

(b) By the high standing and reputation of the managing directors.

(c) By the nature of the offices, their appointments, furniture, equipment, and the type of clerical assistants.

(d) By the courtesy of all persons to patients, their friends, and particularly to other physicians.

(e) By the efficiency and honesty employed in diagnosis, prognosis and other professional services, as well as by the percentage of cures and the psychological satisfaction given the public.

(f) By the staff's relation, activities and co-operation with their fellow physicians and with charitable institutions.

(g) By research work.

(h) By medical papers read and published.

If actuated by the right spirit the staff will keep itself so busy with ethical propaganda that the members will have little time to be unethical.

CONCLUSION

We may safely conclude that a group of medical men with a variety of training, actuated by right ideals and willing to work and co-operate; managed by a directing head properly trained; working under a sane business and professional policy; with finances arranged to give satisfaction to the workers and sufficient backing to carry them through storms; proper contact with the public in such a manner as to insure confidence; followed by actual results in diagnosis and treatment such as the people demand, a group will succeed. But like a ship at sea, one leak will be sufficient to sink it.

THE USE OF BASIC DIETS IN THE TREATMENT OF NEPHRITIS *

By W. D. SANSUM, M. D., Santa Barbara.
From the Potter Metabolic Clinic of the Santa Barbara Cottage Hospital, Santa Barbara, Calif.

SUMMARY

By the employment of what we are pleased to call a "basic diet," the urinary acidity may be easily reduced to a pH of 7.00 or better.

On such diets patients with chronic interstitial nephritis appear to improve, as evidenced by a decrease in blood pressure, albumin and casts in the urine and other symptoms of nephritis and arterial hypertension.

Before discussing the dietary management of nephritis, it will be well to review briefly the various forms of nephritis. Strange as it may seem, authorities have not agreed on a definition for nephritis. Even Osler, with all his clinical experience, avoids the issue by giving no definition. Henry A. Christian defines nephritis as a diffuse, progressive, degenerative, or proliferative lesion, involving renal parenchyma or interstitial tissue or both.

For practical purposes, however, the presence of albumin in the urine of kidney origin is the most reliable sign of nephritis. The phrase "of kidney origin" is inserted because too frequently a hasty, incorrect diagnosis of nephritis is made whenever albumin is found in the urine, regardless of its source. Urine from a female patient may contain sufficient normal, vaginal secretion or desquamated epithelium to give a distinct test for albumin. Clean or even catheterized specimens of urine should be examined before judgment is finally passed. Even catheterized specimens of urine, in cases of cystitis, may contain sufficient pus to give

* Read before the sixty-sixth semi-annual meeting of the Southern California Medical Society, held at San Diego, April 7, 1922.

a test for albumin when no nephritis is present. A careful, serious attempt should, therefore, be made to be sure that albumin is present, and that in all probability the albumin is of kidney origin. The diagnosis of so serious a disease as nephritis in a patient should not be made hastily, but only after all the evidence has been examined and carefully weighed.

Granted a urine containing albumin, the problem which presents itself first is the type of nephritis present. In the final analysis, there appear to be four chief types of nephritis. Without sub-classifying further, and without discussing the mixed types—for a single person may have all four types at once—let me present a classification briefly, with a clear picture of each uncomplicated type:

1. Simple albuminurias, transient in nature, with no gross lesions in the kidneys.
2. Parenchymatous nephritis, involving primarily the parenchyma, i. e., the glomeruli, the convoluted tubules, the loops of Henle and the collecting tubules.
   (a) Acute which becomes
   (b) Chronic if the etiology factors continue for a long enough period of time.

(This is the wet type of nephritis first described by Bright.)

3. Chronic interstitial nephritis, in which the blood vessels of the kidneys are primarily involved, together with varying degrees of blood vessel involvement all over the body.

(This is the dry type of nephritis first described by Bright.)

4. The surgical kidney, i. e., tuberculosis, pyelitis, abscesses, tumors, and stones.

Except for the addition of the albuminureas, this is the classification advocated by William J. Mayo.

This classification differs only in minor details from that advocated by Henry A. Christian, for he divides chronic nephritis into the wet forms without increased blood pressure, the dry forms with increased blood pressure, and the mixed forms.

He discusses essential hypertension in a separate section because of the minimal lesions sometimes found early in the kidney; but states that this condition progresses into chronic, interstitial nephritis.

(1) *Simple albuminuria,* transient in nature, and with no permanent, gross lesions in the kidney. Osler's detailed discussion of this condition is so well known that a repetition is unwarranted. Aside from the albumin in the urine, there are usually no symptoms referable to a nephritis. The patient is promptly cured when the systemic infection runs its natural course or other causes subside.

(2) *Acute parenchymatous nephritis.* This, according to Osler, is an acute, diffuse nephritis, due to the action of cold or of toxic agents on the kidneys. Infections of the tonsils, teeth and sinuses, scarlet fever, acute syphilis, septicemia, and chronic suppuration cause by far the greatest number of cases of this type of nephritis. The toxemias of pregnancy probably rank second. Extensive skin diseases, extensive burns, carbolic acid, turpentine, and mercury are occasionally found as etiological factors.

The kidney, in the beginning, is a large, red kidney. A generalized edema is usually present; there is a large amount of albumin in the urine with many casts, and very frequently red blood cells. The blood pressure is practically normal, except in the toxemias of pregnancy. The blood chemistry is normal, unless a temporary anuria is present. The attack may entirely subside if the infection is cured or the toxic substance removed. If the etiological factor remains, this type of nephritis passes from the acute parenchymatous type into the chronic parenchymatous type. Due to fatty changes from malnutrition, the kidney becomes a large, white kidney, which may become progressively smaller as the parenchymatous tissue degenerates.

Chronic tonsillitis and sinusitis, which are very apt to be overlooked, are the most common causes of this type of nephritis. Whenever a patient is seen who has had either a continuous or intermittent albuminuria, with a normal blood pressure, this is usually the type of nephritis present. So important is the blood pressure in a differential diagnosis of the various types of nephritis that this is frequently the first condition that should be inquired into. During the past year, we had two very typical cases, both in young women, who gave a history of having had albumin in the urine for a long time, and in whom a generalized edema was present on admission, and who gave a history of having had intermittent attacks of generalized edema. In both of these cases, atypical, chronic, generalized sinusitis was present. In one case, the drainage of the ethmoidal cells was obstructed by a large polyp, following the removal of which the patient's edema entirely disappeared, and the albumin decreased to a faint trace. This type of nephritis is curable to the degree to which the existing toxic source—which is usually an infection—can be removed. Both the acute and chronic forms are looked upon by Ebright as a toxemia which affects the remainder of the body, as well as the kidneys, which aids us in understanding the generalized edema.

(3) *Chronic interstitial nephritis.* The cause of this type of nephritis is unknown. It certainly does not follow the chronic parenchymatous type just described. The kidney becomes progressively smaller, with the blood vessels rather than the secreting tissue primarily involved. In this type of nephritis, the attention must be centered on the lesions in the kidney. It is a generalized disease, involving, primarily, the small blood vessels of the entire body. The symptoms depend largely upon the degree of involvement of these vessels in the various parts of the body. There is no edema. The albumin in the urine is always small in amount, and frequently is not found unless careful search is made. Hyalin casts are usually seen, but

no red blood cells. The blood chemistry becomes progressively higher as the kidneys become more involved. The blood pressure is always high. This is the most important differential point. The presence of high blood pressure, except in the toxemias of pregnancy already mentioned, regardless of how little albumin is found in the urine, and even if none is found, is sufficient evidence upon which to make a differential diagnosis of chronic interstitial nephritis. This statement is purposely dogmatic, but authors like Henry A. Christian and others, who describe cases of essential hypertension, frankly admit that eventually such kidneys will show clinical signs of true nephritis. Very frequently the patient leads an active, strenuous life with no untoward symptoms until near the end. As the small arterioles and capillaries all over the body become less elastic, it takes more force to drive the blood through them. The heart, therefore, enlarges, thus increasing the blood pressure, and eventually a stage is reached where either a diseased blood vessel breaks in the brain, resulting in apoplexy with sudden death, or paralysis; or the heart, with its chronic myocarditis, fails because it can no longer stand the increased load of high blood pressure in addition to its usual load. Sometimes the patient complains of impaired vision. An examination of the eyegrounds shows the sclerotic condition of the blood vessels. This condition is not due, however, to the kidney condition. The eye, heart and kidney conditions are a part of the general picture of arterial disease.

This is the type of nephritis which is very difficult to include in a comprehensive definition of nephritis, and eventually this disease may be classified as a distinct, arterial disease. As stated before, the etiology of this disease is unknown, and, therefore, since it cannot be attacked at its source, the disease to date is incurable.

(4) *Surgical nephritis.* There are many forms of this disease, each form depending upon the causative factor, such as tuberculosis, pyelitis, the various forms of abscesses of the kidney, benign and malignant tumors and kidney stones. In each case, the pathology and symptoms are different. The treatment is surgical. The prognosis depends upon what surgery can do for these cases. This is about the only form of nephritis which is painful. The pain in the back (of the well-known patent advertisements) is usually not of kidney origin, but very frequently a lumbago of toxic or infectious origin.

The following case report illustrates how a patient may have all forms of nephritis at once:

CASE REPORT

A woman, sixty-five years of age, who had enjoyed excellent health all her life, and who, except during childbirth, had never needed a physician, was taken acutely ill, following her fall house-cleaning. She was short of breath. The eyelids were swollen. The lips were cyanotic. The liver was tender. The legs were badly swollen. The heart was markedly enlarged. The blood pressure was 200 systolic and 120 diastolic. The urine contained large amounts of sugar, albumin, and pus. The high blood pressure indicated an advanced, arterial disease, associated with atypical, chronic interstitial nephritis.

The burden of the fall house-cleaning, added to the high blood pressure load on the diseased heart, had caused it to fail. With the first shortness of breath, there was probably a little increase in albuminuria of the No. 1 type, but as the heart failed, first an acute, then a chronic, parenchymatous nephritis developed. This accounted for the edema and the large amount of albumin, which is not seen in the pure type of chronic interstitial nephritis.

The pyuria was due to a marked cystitis and ascending pyelonephritis, probably aggravated by the diabetic condition. In addition, this patient was practically blind from the so-called albuminuric retinitis, and eventually died from a stroke of apoplexy.

This discussion has been necessarily long, but briefly let us sum up the more essential points.

Granted a patient who has had albumin in the urine for some time: If the blood pressure is high, regardless of what other conditions may be present, and even if the laboratory has failed to find albumin in the urine, a diagnosis of chronic interstitial nephritis should be made. The treatment is difficult and the prognosis is bad.

If the blood pressure is low, and the albumin has been present for some time, it is either the chronic parenchymatous or the surgical type. If there is no pus in the urine and the patient has had no pain referable to the kidneys, one can rule out most of the surgical types, leaving the chronic parenchymatous type as the most probable diagnosis.

Dietary Treatment.—In the treatment of all forms of nephritis, the first essential is obviously the removal of the cause wherever possible, and in most of the cases of types 1, 2, and 4 this can be done. In type 3, since as yet the cause is unknown, this cannot be done. In all cases, it is advisable to place the patient on the most soothing kind of diet possible. It is fairly well agreed that anything which has a tendency to keep the patient toward the acid, harsh side of life will certainly have a tendency to make him worse, whereas measures which will keep the patient on the normal, alkaline, soothing side of life will have a tendency to improve the condition of the patient, both in this and in many other types of disease. The acid-base balance of the body, its variation and regulation, has been discussed by Henderson and Van Slyke.

In terms of hydrogen ion concentration the pH of the body is 7.35, with normal variations probably in the second decimal place. The body reaction is, therefore, always slightly alkaline. Van Slyke states that, "Under extreme, abnormal conditions the pH may fall as low as 6.95, but before this point is reached it appears that coma occurs, and, from the fact that lower pH values have not been observed, it is doubtful that further decrease is compatible with life." The kidneys assist in maintaining a normal body pH by changing such substances as the alkaline sodium phosphate presented to them by the blood to the acid sodium phosphate which they excrete. The hydrogen ion concentration of the urine is one of the means

whereby the effort of the body to maintain a proper pH can be measured and indirectly indicates the dietary mode of life. A pH of 4.35, which is frequently seen in nephritic urine, indicates an acidity 1000 times as great as that of the normal body. The hydrogen ion concentration of such urine can easily be reduced to a pH or 7 or better.

The patient is given what we are pleased to call a basic diet. This is selected from the foods which are either neutral in nature, or which in the course of their metabolism tend toward the alkaline side of life. The following tables and diets have been prepared with these objects in view. They appear to explain concretely the fundamental principles which underlie the various forms of nephritic diet which have withstood the test of time.

The Dietary Control of the Acidity of the Body—There are a number of diseases which are improved when the general acidity of the body is reduced. This is especially true in the treatment of nephritis (kidney disease), high blood pressure, migraine, rheumatism, etc. This is easily accomplished by selecting the foods which are basic (alkaline) in nature. Such lists of foods have been prepared by Sherman and Gettler from ash analyses and tested in man by Blatherwick. The following tables have been prepared from their work and are now being used in the selection of basic diets:

Neutral Foods—These may be used in reasonable amounts desired by the patient unless otherwise stated.

Butter
Corn starch
Cream
Sugar
Lard
Tapioca

Acid-producing Foods — Many of these foods should not be used. A few of the less acid ones, such as the cereals and breads, may be used in the amounts specified for each case. The total excess of acidity over base is expressed in terms of cc. of a normal solution.

	Per 100 grams
Bread	2.7
Bread, whole wheat	3.0
Corn	5.95
Crackers	7.81
Cranberries	....
*Eggs	11.10
Egg white	5.24
Egg yolk	26.69
Fish, haddock	16.07
Fish, pike	11.81
Meat, beef, lean	13.91
Meat, chicken	17.01
Meat, frog	10.36
Meat, pork, lean	11.87
Meat, rabbit	14.80
Meat, veal	13.52
Oysters	30.00
Oat meal	12.93
Peanuts	3.9
*Prunes	....
Rice	8.1

* The ash of these articles is alkaline in nature, but because of the precursors of hipuric acid contained by them, they increase the acidity of the body.

Base or Alkali Producing Foods—In general, all vegetables, nuts, and fruits with the exception of prunes, plums, and cranberries are basic in nature. A partial list of such foods is given below. These may be used in reasonable amounts desired by the patient. The total excess of base over acid is expressed as before.

	Per 100 grams
Almonds	1.78
*Apples	3.76
Asparagus	.81
*Bananas	5.56
Beans, dried	23.87
Beans, lima, dried	41.05
Beets	10.86
Cabbage	4.34
Carrots	10.87
Cauliflower	5.33
Celery	7.78
Chestnuts	7.42
Currants, dried	5.97
Lemons	5.45
Lettuce	7.37
Milk, cows	2.37
*Muskmelon	7.47
*Oranges	5.61
Peaches	5.04
Pears, dried	7.07
*Potatoes	7.19
Radishes	2.87
Raisins	23.62
Turnips	2.68

* These foods have been found, experimentally, by Blatherwick to be the most efficient in reducing the acidity of the body.

BASIC (ALKALINE) DIET
Example as served

Breakfast

Baked Apple With Cream
Bacon
One Slice Toast Butter
Marmalade
Orange Juice Coffee

Dinner

Cream Soup
Baked Stuffed Potatoes Beets in Cream
Combination Salad
One Slice Bread Butter Olives
Pineapple Bavarian Cream

Supper

Escalloped Potatoes Buttered Peas and Carrots
Fruit Salad
One Slice Bread Butter
Nut Ice Cream Cocoa

Mid-meal Diets

10 A. M.	3 P. M.	9 P. M.
Milk	Fruit Juice	Hot Milk

(Note—Cornstarch is used as a thickener. Lemon juice is substituted for vinegar in salad dressing.)

Routine hydrogen ion concentrations are made on twenty-four-hour specimens of urine. A pH of 7 or better is considered satisfactory. The simple, colorimetric method described by Clark is employed.

Whenever the blood chemistry shows a retention of nitrogenous end products the protein is limited to the minimal needs of the body, about two-thirds of a gram per kg. Whenever the blood chemistry or urine shows a retention of sodium chloride the salt intake is limited.

The most satisfactory results are seen in the ambulatory cases. Many such patients are over weight. They have a cathartic colitis either from pernicious habits or because purging has been used therapeutically in the treatment of the high blood pressure. They are frequently anemic. On a diet containing an abundance of fruits and vegetables, they lose weight with no discomfort. They have from one to three soft, formed stools per day without the use of cathartics. The gastric and intestinal distresses soon disappear. The haemoglobin improves even though no medicinal iron is given. There is less albumin and there are fewer

casts in the urine. The blood pressure often falls except in those severe, terminal stages of chronic interstitial nephritis with all the typical complications.

We adopted this simple plan about eighteen months ago. A brief summary of the history of one of the first cases treated will give an idea of the results obtained.

CASE REPORT

Mrs. S. First seen December 12, 1920; age 64; weight 172 pounds. She complained of shortness of breath, dizzy spells, marked gastric and abdominal distress and a general run-down feeling. She had been taking salts each morning on the advice of her physician. The blood pressure was 210/110. Traces of albumin and hyaline casts were found in the urine. The patient was given a basic diet with the fats and sugars limited, because of her overweight. The H ion concentration of the urine was tested from time to time and found to be close to a pH of 7.0. She gradually lost weight, with no discomfort. The abdominal distress disappeared. The bowels moved normally. Some of the specimens of urine contained no albumin or casts, and the blood pressure fell as follows:

Dec. 12, 1920—blood pressure	210/110	weight 172	lbs.
Dec. 29, 1920—blood pressure	200/110	weight 171	lbs.
Jan. 12, 1921—blood pressure	195/110	weight 168	lbs.
Jun. 1, 1921—blood pressure	170/110	weight 148.25	lbs.
Nov. 1, 1921—blood pressure	172/115	weight 147.	lbs.

Patient stated that her bowels were moving normally, the gastric distress had disappeared, and that she was feeling better than she had felt for a long time.

Feb. 23, 1921—blood pressure	170/95	weight 160.5	lbs.
Apr. 20, 1921—blood pressure	160/110	weight 148.75	lbs.
Jun. 1, 1921—blood pressure	170/110	weight 148.25	lbs.
Nov. 1, 1921—blood pressurs	172/115	weight 147.	lbs.

Patient had returned from a summer in New York and Cape Cod, and had felt exceptionally well during the whole time she had been away.

April 26, 1922—blood pressure 160/105 weight 148 lbs.

Nurses Practicing Medicine in New England—Considerable interest has been aroused concerning the problem presented by nurses who have been treating injuries without having secured attendance by physicians. This matter has been frequently referred to by physicians who have felt that nurses have assumed responsibilities not warranted under our laws, and in some instances doctors have felt that the activities of nurses have in a very definite way invaded the field of medical practice, although the nurses have been sufficiently warned. Since the alleged practice of medicine by nurses has seemed to be on the increase there has been no reason why the authorities should decline to act. The Board of Registration in Medicine has tried to bring about compliance with the law without resorting to drastic measures, but reports of questionable methods have become so common and demands for action have been so insistent that it became necessary to report the facts in two recent cases to the prosecuting authorities. . . .

The whole question is complicated and delicate, but it can be solved by the nurses themselves, even though managers of industrial plants and some physicians try to induce nurses to practice medicine either as a convenience or to save expense.

The general purpose of the laws governing medical practice is to protect the patient from incompetent service, and nurses should observe the requirements because it is a law and also because sooner or later some nurse may attempt to render a service which is beyond her ability.—(Boston Medical and Surgical Journal, April 6, 1922.)

CARDIAC DYSPNOEA OR RATHER CARDIAC SHORTNESS OF BREATH

A QUESTION OF RESERVES

By HARRY SPIRO, M. D., San Francisco

In this discussion an attempt will be made to answer the following questions:

1. Is dyspnoea caused by diseased muscles or valves of the heart, and if so, why does not every patient with organic heart disease complain of it?

2. Is dyspnoea due to an edema of the alveolar tissue of the lung, and if so, is the edema always present? If it is, why does dyspnoea only show when the patient exercises and disappears almost immediately upon rest?

3. Is dyspnoea due to a lack of oxygen in the blood, and if so, why cannot these patients assimilate the oxygen of the air as well as any other person?

4. Is dyspnoea due to an improper exchange of CO_2 between the blood and the alveoli of the lungs, and if so, is this a heart or a lung fault?

5. Is dyspnoea due to an acidosis of the tissues or of the blood, and again what is the relation between the heart and acidosis?

6. Is dyspnoea due to a lack of tone or weakening, or partial paresis of the muscles of respiration like the diaphragm, and intercostals, and if so, why call it cardiac dyspnoea?

Dyspnoea, difficult breathing, or shortness of breath, will bring a patient to the physician more quickly than almost any other symptom, because it is a symptom which interferes so materially with his comfort, with his sense of well-being, and earning power. Difficult breathing is unaccountable to the patient. He may awaken in the morning feeling fine and refreshed, but the least effort makes him sit down, not because he is tired, but because he is short of breath. He may come home in the evening, eat a fairly hearty meal, and afterwards have an extraordinary amount of discomfort and shortness of breath, particularly so if he should attempt any exercise. Such, in brief, is the commencing of a chain of symptoms, which, as Facio says, are gradual, progressive and fatal. Just as this symptom is so important to the patient, so it at once becomes to the physician, because he knows that such symptoms are not imaginative. The physician recognizes dyspnoea as a distress signal, a clear call for help from the vital centers of our bodies. While it is true that shortness of breath may have underlying causes other than the heart, it is advisable to prove the heart innocent, particularly if the shortness of breath is in direct relation to moderate effort.

How is dyspnoea brought about? An individual with disease of the valves or muscles of the heart may go through life without knowing there is anything wrong. He may get sick, and get well again. He may eat, drink, smoke and work without much distress. Occasionally he does things to excess, and on such occasions the excess adds an "accumulating resistance" to the heart's action—accumulating because the additional strain has caused some partially degenerated or weakened heart muscle to give way completely, and on each such occasion a call is made on the reserve power

of the heart's muscle because it is the reserve power that has carried the defective heart to this point. If the heart hypertrophies properly—by each ventricle keeping its balance of power—well and good. If the reserve power becomes partially depleted, the strain may be greater on one or the other ventricle with the result that the hypertrophy is irregular, because one of the ventricles becomes out of proportion in power to the other.

One of the interesting episodes in the annals of medicine was the controversy between Welch and Sahli over the cause of pulmonary edema. As a result of extensive experiments both teachers were proved partially correct. Sahli claimed that edema of the lungs was caused only by some local irritant or poisoning or infection, and that if Welch was correct he was wrong anyway, because, as Sahli said, "Welch's theory did not apply to clinical cases." Welch had claimed that the edema could be caused by a disproportion between the powers of the two ventricles, resulting in a damming back of the blood in the lungs or improper circulation of blood in the lungs, and so edema was produced, and today we know that is a fact. The right ventricle may pump the blood fast enough into the lungs, but the left may not drain it out properly. If the left ventricle shows signs of distress the condition is recognized by simply feeling the radial pulse, but if the right side partially gives way, the symptoms are not so easily judged. Merely a cough and moderate cyanosis may be the only symptoms, or even if the patient is feeling fairly well, a few rales of different qualities at the base of the lungs may suggest a moderate edema of the lungs, but perhaps no severe dyspnoea yet, so we will go further, remembering how a weak heart produces edema of the lungs.

We will now consider lack of oxygen in the blood. One of the facts definitely proved during the war was that a very moderate edema of the lungs interferes materially with the proper absorption of oxygen. As with the reserve power of the heart muscle, so it is with oxygen. The blood retains a reserve supply of oxygen of about three times as much as is needed. Experiments by Lundsgaard, Steadie, and others show that the total oxygen carrying power of arterial blood is about twenty volumes per cent. We use about five and one-half per cent at rest, and perhaps ten to twelve per cent with severe effort. After rest the reserve supply is immediately replenished. If an obstruction occurs in the way of the oxygen's ready absorption, as is the case in edema of the lungs, the reserve oxygen gradually becomes depleted. The patient may go on for some time without a serious disturbance, as there is no actual lack of oxygen even after manifest injury to the lungs, because the tissues will absorb their quota of oxygen even though the supply is limited. Sooner or later, as the reserve nears exhaustion, the respiratory center in the brain takes note of it and sends out a call to the respiratory muscles for more work and faster work. Here again we see one of nature's resources, another of the reserve systems, this time called the pulmonary reserve. Actually this is the greatest amount of air the lungs can inhale after the greatest expiratory effort. Ordinarily, we utilize about five liters of air at ordinary respiration at rest per minute. This amount can be increased ten to twelve times without the person being unduly conscious of it. An increase to sixty or seventy liters is common, but there is always a return to the former level. However, in a patient with the above symptoms of insipient incompetence, resulting in a moderate edema of the lungs, the so-called threshhold is raised from five to twenty liters, and so is that much nearer the upper limits of the pulmonary reserve, and the reserve instead of being fifty or sixty liters per minute is now thirty or forty liters per minute, and so an effort that would pass unnoticed in a normal person would to one in this condition become noticed because of the increased respiratory effort needed.

The question of the actual method, not the underlying cause, of this depreciation of the pulmonary reserve or vital capacity is still under active investigation. Rooney of the Stanford cardiac clinic is now doing some work in this line, so I prefer not to discuss it, except to say that probably the air spaces may be encroached upon by the enlarged heart itself acting by compression of lung tissues and by the increased amount of blood in the lungs. The dilated veins may interfere with proper expansion of some air vesicles and so cause overexpansion of others. This, if true, may interfere with the proper draining of the residual air, and even though the respiratory rate is increased and the total air inhaled and exhaled is greater, still the oxygen is not properly absorbed. Now the respiratory center is calling on the respiratory muscles for heavier work, as a proper level of oxygen must be maintained. The respiratory muscles, while tired and probably weakened, still respond. Exhalation ceases to be a nearly passive effort and now is a severe effort, but a time arrives when the respiratory muscles produce more of the products of fatigue than the weakened heart muscles and lack of oxygen can eliminate or neutralize. This product of fatigue also is a stimulant to the already overexcited respiratory center, and the respiration on the least effort over the ordinary becomes quicker and more shallow—another link in nature's chain of defense has become weakened.

We are now in front of one of the last lines of defense which in time of development may be one of the first. It is placed last in the discussion because it is one of the last to break permanently. So far, all processes discussed were shown to depend on the question of reserves, each one of the different vital functions were shown to have tremendous reserves or the power to produce reserves, and as the reserves were encroached upon the patient's body was called upon for extra effort. In other words, extra effort takes the place of former reserves; the reserve we now face is the popular alkali reserve, the question of acidosis, the question of carbon dioxide interchange. This is called the internal respiration. Manifestly, it is impossible to condense the volumes that have been written on this subject into one or two pages.

Physiological and biological chemistry is deep water reasonably safe for Priestly, Heldane or Fisher, but not for most physicians. However, as we said, the internal respiration is the interchange between the tissue cells, the blood cells, and the blood plasma of CO_2 and oxygen, and certain acids and bases. CO_2 is an end product and is capable of forming H_2CO_3. Now, the greater the accumulation of CO_2 in the blood, naturally the more acid the blood would become, if it were not for the great alkali reserve. The blood must not become acid; if it did, death would very quickly result. Nature has provided an almost permanent alkali level, and as a safeguard to this level has provided tremendous reserve alkali and also the power to produce reserve alkali. The symbol of the alkali reserve of the body can be taken as the sodium bicarbonates. If the CO_2 accumulates too fast so that the CO_2 pressure in the blood rises, a reaction takes place between the blood corpuscles and the sodium chloride in the plasma, resulting in an absorption of the chlorine to form H.Cl., which enters the red blood corpuscles, leaving sodium free. The sodium combines with the CO_2 and forms acid sodium carbonate, so that instead of an acid condition, we really have an alkali condition in the blood; but before this interchange has taken place the CO_2 has stimulated the hypersensitive respiratory center, which calls upon the respiratory muscle for renewed efforts, and large amounts of the CO_2 are immediately eliminated. The kidneys also eliminate large amounts of the bicarbonate that is formed, so that the alkali level which was temporarily raised is again equalized, but the reserve is lessened. The chlorine may now leave the red blood corpuscles and again combine with the soda forming Na Cl., and thus setting free enough CO_2 to maintain its proper level. The CO_2 level is as important as the oxygen level, and if the CO_2 is decreased too greatly it may not return to its proper level, thereby causing disaster. Reserve alkalies having been washed out by the kidneys—an ordinary effort that might pass unnoticed—calls for extra stimulation by the respiratory center, and as there is not enough alkali reserve on hand it must manufacture alkali for the occasion, and so we have the dyspnoea of effort—easily produced because of lack of reserve.

The chemists have experimentally proved that a proper oxygen level must be maintained or death result, and death results even though the oxygen is brought up again to its former level. A CO_2 level also must be maintained. Upward tendencies of the CO_2 level are equalized by the respiratory apparatus. If the level descends below a safe point, it cannot be again raised even by giving CO_2, and a Haemolysis takes place and death results.

There also is an alkali level. If this falls too low, nature reproduces alkali. We should not feed alkalies when nature does not want it, even though there is a lack of alkalies. It is the level that is of utmost importance. If the alkali level is without reserve, or reserve power partially depleted, it would be of use to furnish alkalies, provided we could regulate the respiratory apparatus so as not to reproduce the results that brought on the original trouble. The loss of alkali is not the cause—it is the lack of oxygen that started the trouble.

With the above thoughts before us we return for a moment to the question of diagnosis and treatment. Every case of dyspnoea is not due to the heart, and every case of heart disease need not have constant dyspnoea. Effort can produce dyspnoea in a person whose heart is sound, but dyspnoea is one of the first and most reliable symptoms that the heart is diseased, and in a case of mild dyspnoea a diagnosis can, as a rule, be made because the physical examination can be made leisurely and the defect in the heart proved. But how about the sudden alarm at night, and you walk in on a patient sitting or propped up in bed, as a rule pale or slightly cyanotic, and covered with perspiration, breathing rapidly and labored, foam coming from the mouth, a pulse fast and sometimes irregular? This may be a first attack, and if that is the history obtained from the family, it most likely is a heart attack and should be treated as such, particularly if the attack is attributed to some excess of food or work. Compare this to ordinary asthma bronchial in type. This is generally seasonal, and while there must be a first attack, it is usually long before a physician is called. The patient usually does a great deal of the talking. He is very sick, but does not impress the physician that he is desperately ill. Between his gasps and his wheezes he tells of repeated attacks of bronchitis on exposure to weather as the cause, and after being relieved will still cough up large amounts of purulent sputum. The expiratory effort in bronchial asthma is prominent. Both inspiration and expiration are difficult in cardiac asthma and the rate faster. If the attack stops suddenly, as it may, the patient may sleep and awaken apparently cured, or he may have a severe bronchitis as a result of the exposure during the attack. This is dangerous because it is easy to neglect the heart and think that after all the patient did have a real bronchial asthma. The next attack, if treated as ordinary asthma, may result in sudden death.

The treatment of cardiac dyspnoea is first rest, and more rest. Oxygen used vigorously is valuable. Haldane and Priestly have proved that recoveries from lung edema by the use of oxygen occur where proper methods of administration are employed. Digitol, digitaline, tincture of digitalis are indicated and should be given to the physiological limit. It is advisable to be careful of adrenalin. Atropin blocks the vagus, and thus increases the difficulties in lowering the heart rate. Strychnine, camphorated oil, whisky and caffine are helpful and do not interfere with digitalis. Morphine and oxygen given together are helpful. Without oxygen, morphine is moderately dangerous, because it depresses the respiratory center which must be kept up to its work.

Some patients may die quietly and peacefully

after administration of alkalies while others die in convulsions, with or without alkalies. This method of treatment, therefore, is of questionable value. McLeod advises giving alkalies and testing the urine to determine if acidosis is present. Whitney warns against this procedure and with good judgment. He advises giving a diuretic or a physic at the same time. Too much alkali should not be given, particularly if the kidneys are defective, because the same conditions caused by surplus of acid can also be caused by too much alkali. Keeping the urine neutral is probably the best procedure. The patient should be kept in a semi-reclining position because reclining may embarrass the right heart. The lungs should be stretched by breathing exercises for a few moments several times a day. Caution is necessary to avoid overexercising, as it is possible to embarrass the right heart and right coronary artery. Epsom salts is one of the best laxatives if the kidneys are functioning properly. For a very large and full-blooded patient, venesection is sometimes a good procedure. Even though it reduces the oxygen carrying power of the blood it may relieve an overstretched vascular system.

A simple, though not absolutely reliable, test for acidosis is to give bicarbonate of soda until the urine becomes alkaline, and then watch the amount of bicarbonate necessary to keep the urine neutral. Less than four grams per day is normal and safe to use if neutral red or sulphophenolthalein is used as an indicator.

212 Stockton Street.

THE SLANDERER

The very name invokes loathing. Though more or less in human form, this degenerate remnant of the silurian age is the most contemptible of creatures. The scandalmonger is disliked, the liar is despised, but the slanderer is loathed. Using falsehoods or facts that are distorted as some would juggle statistics, the slanderer spreads a most subtle poison that blasts lives and reputations. Slander cannot be controlled any more than you can stop a lie, once it has gained credence. Compared with the social diseases, it is the greatest evil of our age. The slanderer is more dangerous and despicable than those misguided enemies of society who use bombs and poison secretly.

Whenever you discover a slanderer posing as an honorable member of our profession, let your conscience be your guide, but be sure you do your full duty.—Malsbary, editorial in the Southern California Practitioner.

Speaking of Babies—According to George Ade (Cosmopolitan, February) the old saying that "the hand that rocks the cradle rules the world" is now changed to "the hand that rocks the cradle should be amputated." There is more of humor and interesting philosophy in the article.

"The human race is, according to a guess by H. G. Wells, 75,000 years old, and only in the last twenty-five years has any one known how to welcome a baby and take care of it. All those who survived during the preceding 74,975 years were just plain lucky.

"The first impression gained by a baby of the nineteenth century must have been that Earth is inhabited by elderly people, all females except one and all wearing spectacles.

"The newly arrived of 1921 probably decides that the world is walled with white, tinctured with anesthetics and peopled by efficient internes and calm nurses."

THE PLACE OF PATHOLOGY IN THE PRACTICE OF MEDICINE*

By WALTER V. BREM, M. D., Los Angeles

If one should confine himself strictly to the subject of this paper, his task would be indeed a gratuitous one, for there is certainly no one in touch with the progress of medicine who does not recognize the practical assistance that the pathological laboratory may give to a clinician. There are, of course, some clinicians who have become discouraged in the use of laboratories by reason of incompetent service and because of the fact that ill-informed or overenthusiastic laboratory workers have advanced too often unwarranted claims that could not be fulfilled.

On the other hand, there are many clinicians who are oversanguine regarding the service that a laboratory may render, and others to whom laboratory work is like a simple test tube experiment, that he who runs may read. The former do not appreciate the limitations of the laboratory, and the latter do not understand the difficulties of the work and the necessity of its being directed by an experienced pathologist.

SCOPE OF PATHOLOGY

Pathology, in its broad sense, is the study of the causes of disease, of the structural changes (macroscopic, microscopic and chemical) underlying disturbed function, and of objective manifestations of altered structure and perverted function. Pathology is not limited, as is so often assumed, to autopsies and the microscopic examination of tissues, but the term covers the underlying conditions and objective manifestations of disease. A fairly good foundation in pathology is, therefore, a fundamental prerequisite for a clear conception of disease, and it is as essential for a clinician to be able to visualize common structural changes and to think in terms of pathology, as it is for the pathologist to have had sufficient clinical experience to hold in his view the welfare of patients.

SELECTION OF A PATHOLOGIST

Having acquired a good fundamental knowledge of pathology, so that he knows what examinations are indicated in given conditions, the busy clinician is confronted with the problem of how to secure the pathological service needed in his practice. No longer can his own office encompass the vast field, no longer can he himself find time to master the technique and perform the complicated tests indicated, and no longer can he train his own technician and supervise the work except in a very limited way. Out of this need the modern clinical laboratory has developed, with its departments of tissue pathology, bacteriology, serology, biochemistry and clinical microscopy. The laboratory is no longer limited to tests of urine for albumin, examinations of sputum for tubercle bacilli, and blood counts (relatively simple tests in the department of clinical microscopy), but its work deals with the essential

*Address in the General Session of the Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May 15-18, 1922.

nature of disease and its ramifications extend into every field of medicine.

It is obvious that one who specializes in "the underlying conditions and objective manifestations" of disease, of structural and functional deviations from normal, must have as a foundation a careful training in the normal phenomena of living tissue —that is, in anatomy, histology, physiology, physics, and chemistry. Then one is prepared for the study of the abnormal phenomena, tissue pathology, bacteriology, serology, clinical microscopy, and pathological chemistry; and in order to correlate this knowledge with the need of clinical medicine, the specialist in pathology should have a broad clinical perspective, an appreciation of the problems of the clinician, and last but not least, an understanding attitude toward the patient.

There is probably no other field of medical practice more exacting in its demands. In the breadth of its scope and in its importance it is second to none, and there is every reason why its dignity and integrity should be upheld by preserving for it the highest ethical standards. On the contrary, we have seen the clinical laboratory degraded and discredited, not only by the invasion of laymen and unqualified would-be pathologists, but by the support that many of the medical profession have extended to those who have attempted to exploit a noble specialty by campaigns of boastful advertising, solicitation, rate-cutting, and insidious rebating.

That members of the profession have aided and abetted the pseudo-pathologists referred to is due, I believe, to a misunderstanding of the position of pathology and of the qualifications desirable in a pathologist, and, also, to lack of realization that the insidious appeal of these persons is an attack upon the ethical standards and traditions of the medical profession and is degrading to one of the fundamental specialties of medical practice.

The problem of the clinician in securing adequate pathological service is, therefore, the old problem of selecting the qualified man, and one imbued with the ideals of the medical profession. This is comparatively easy to do. There is a reasonable excuse for members of the laity who patronize poorly qualified doctors and even charlatans and quacks, but the records of physicians are wide open to other physicians and they have the knowledge necessary for justly appraising the value of the records.

It has been said over and over again that an erroneous laboratory report is worse than none at all. Many illustrations of the truth of this statement have come to our attention, and it seems apropos to review a few concrete examples.

Tissues obtained by curettage from the uterus of two young women, one 23 and the other 28 years of age, were sent to recent graduates who claimed to be qualified in tissue pathology, that most difficult branch of all pathology. They returned a diagnosis in both instances of carcinoma of the uterus. Hysterectomy was being considered when consultation was sought by the clinicians. The sections for examination were found to be so poorly prepared that it was disgraceful to attempt to use them in making such important diagnoses; but, as far as could be determined from the architecture, there was no evidence of a malignant condition. But for the consultation, these young women might have been subjected to a major operation which would have deprived them of the possibility of having children and altered the course of their lives, and they would have been forced to labor for years under the fearful apprehension of malignant recurrences.

A third similar diagnosis in another case was made by a lay-conducted laboratory, and again the section was atrocious and there could be found in it only two or three glands, and these showed no evidence of malignancy.

Again, a laboratory conducted by laymen reported the blood picture of a patient as that of pernicious anemia, the color index being about 1.4. The prognosis was hopeless and the patient was given expectant treatment for six weeks, when a second examination of the blood with standardized instruments, made by another laboratory, showed the picture of secondary anemia with a color index of 0.7.

Notorious discrepancies in Wassermann reactions have existed so that this truly wonderful test has been at times sadly discredited. The discrepancies have been due, in our opinion, to carelessness in the titration of reagents and the use of "short-cut" systems by men not thoroughly conversant with the principles of the test. This is not a test to be experimented with and modified by technicians, but it requires always the careful consideration and supervision of a student of immunology. By only the most unceasing watchfulness and care can non-specific reactions be avoided, reactions which would fasten upon innocent persons the stigma of syphilis, cause them to suffer the mental anguish of the spirochetæ infected, and subject them to a drastic, expensive and unnecessary treatment. A good number of such cases have come under our observation. The visualization of such an eventuality by those possessing a "clinical conscience" is, I believe, the only thing that will keep strictly up to standard the complicated titrations and other technical procedures of the Wassermann test.

The opportunities for errors in laboratory work are unlimited, and one must be on guard continually to avoid them; he must realize that man, including himself, is exceedingly fallible, and he must be not only willing but eager to repeat and recheck tests again and again when any doubt exists. He must be, indeed, his own most severe critic.

LIMITATIONS AND USEFULNESS OF PATHOLOGY IN MEDICAL PRACTICE

One of the difficulties with which the clinical laboratory has met is that frequently too much is expected of it—that is, that the limitations of various examinations are not fully understood. There are but few laboratory tests which are pathognomonic, and laboratory results should be considered only as evidence in a case, evidence to be weighed in the balance with all the other evidence which only the attending physician pos-

sesses. Such results should be classified and weighed, therefore, with certain symptoms and physical signs which may or may not be the deciding factors in the diagnosis, prognosis or indication for treatment.

It seems scarcely necessary to review in detail the many avenues through which pathology can be useful to the clinician. It does, however, seem advisable to discuss certain services that may be rendered.

In the domain of tissue pathology, necropsies and surgical pathology should be emphasized. There is no stimulus so powerful and no teaching so instructive as the post-mortem examination. Feared by the careless and cock-sure, and sought for by the earnest and humble student, it stimulates thoroughness, enthusiasm and humility as nothing else can do. Indeed, the scientific spirit of the medical profession and of hospitals can be measured with a fair degree of accuracy by the interest taken in securing post-mortem examinations. No hospital is complete without adequate facilities for these extremely important investigations.

It is a popular fallacy that doctors desire post-mortem examinations because of a morbid curiosity. Of course, nothing could be further from the truth, and it is the public who are benefited most, both through the more careful and enthusiastic clinical work stimulated by the examinations, and through the additional knowledge gained. Therefore, it is a matter of vital interest to the public that permission to hold autopsies be given and adequate facilities provided.

The necessity of pathological examinations, by frozen sections at operations or otherwise, of surgical specimens scarcely needs emphasis. But it should be emphasized again that cellular pathology is the most difficult of all laboratory examinations, and that the cellular pathologist requires longer years of experience and study than any other laboratory worker. Even the best trained pathologist is forced to say not infrequently that he is unable to venture an opinion regarding the malignancy of a specimen. He should know always the anatomical source of the tissue and the essential points in the history of the case, for he needs frequently every aid that he can receive in arriving at an opinion.

In bacteriology, vaccines have had their day of the usual exploitation of new therapeutic methods, and out of the confusion have come a few valuable additions to our armamentarium. Among these are prophylactic typhoid and probably yellow fever vaccination and vaccines for staphylococcic infections. Of course, the tremendous value of the old-established vaccines against smallpox and rabies is undisputed, except by doctrinaires and cultists. Some of the other vaccines occasionally appear to produce beneficial effects, but most of them have been disappointing. Of the anti-bacterial serums, three are pre-eminent—the anti-diphtheritic, the anti-tetanus, and the anti-meningitis. The anti-plague, anti-cholera, anti-anthrax and anti-yellow fever serums are said to be of value. Animal inoculations, blood cultures and other cultural examinations of exudates, such as diphtheritic, are of course, of great importance in certain cases.

In the field of serology, the typhoid agglutination test and the Wassermann test stand out above all others in practical value. The agglutination test should be made with a standardized suspension of typhoid organisms (like the Dreyer antigen) or with a suspension of organisms grown at room temperature, which we have found to have practically the same agglutinability as the Dreyer antigen. The incubator-grown bacilli are much more resistant to typhoid agglutinins.

The value of the Wassermann test has been greatly enhanced by the cholesterinized antigen and the ice-box preliminary treatment. The cholesterinized antigen, however, as first introduced (0.4 per cent cholesterine) caused a considerable number of non-specific fixations, and brought about much criticism of the Wassermann test. Very soon after its introduction, our titrations showed that cholesterine in 0.1 per cent did not give the non-specific fixations and that it gave a far more sensitive test than the old antigens. Its sensitiveness has been greatly increased by the ice-box preliminary treatment instead of the water bath incubation at 37° C. We believe that the test made according to this technique is as sensitive as it can be made without danger of the calmity of non-specific fixation.

The new biochemical tests, for several years, have enjoyed a vogue that we have felt has been out of proportion to their clinical value. Some of the chemical tests are, at times, no doubt helpful, especially the study of blood sugar, urea, creatinine, and the phenolsulphonepthalein test. But none of them have supplanted the old and tried clinical and urinary criteria, upon which the careful clinician still lays the greatest stress. The basal metabolism test may be included here, as it deals with the chemistry of respiration. It seems to be a real contribution to our armamentarium in differentiating the cases on the clinical border line of hyperthyroidism, and in indicating the degree of thyroid intoxication.

Clinical microscopy, to which, with tissue pathology, the laboratory was limited not so very long ago, now occupies a less conspicuous though still important place. Urinalyses, sputum examinations for tubercle bacilli, microscopic examination of feces, and blood counts are as imperative in given cases as they ever were. But many of the blood examinations, even those reported in the literature, are of no value because the instruments used were not standardized. Especially is it important to use reliable hemocytometers and hemoglobinometers. The Levy hemocytometer may now be obtained under the stamp of standardization of the Government Bureau of Standards. Every new hemoglobinometer should be standardized when first obtained, and some of them at intervals afterward. Failure to do this is frequently revealed in the literature in case reports of conditions other than pernicious anemia in which the color indices run sometimes far above 1.

Many of the examinations in a clinical laboratory depend for their value upon vigilance in such small details of technique: The correct and repeated titration of reagents, the preparation and renewal

of stains such as the analine gentian violet of Gram's stain and the eosin-methylene blue blood stains, the method of getting specimens, the condition of specimens, the selection of a test when more than one is described, etc. Valuable additions have been made in recent years to the department of clinical microscopy in the dark field examination for spirochetes and in the blood group tests preparatory to transfusions.

The departments discussed are distinctly features of the clinical laboratory, but there has developed another phase of work that merits discussion. Because of its equipment, personnel, and experience in intravenous work, many clinicians have found the laboratory to be of assistance to them in certain other diagnostic and therapeutic procedures such as lumbar punctures, tuberculin tests, blood transfusions, intravenous glucose injections, and anti-rabic treatments.

RESEARCH IN CLINICAL LABORATORIES

In addition to the above outline of work, we feel that every clinical laboratory should be interested in one or more large subjects of investigation. Research, far better than anything else, will preserve and foster a scientific spirit and will inject life into a laboratory. In trying to follow out this idea, our laboratory has been interested since 1912 in the treatment of syphilis with the arsenicals, especially of neuro-syphilis. This investigation over a period of ten years not only has contributed a large and unusual series of cases carefully controlled by blood and spinal fluid tests, but it has aided us materially in developing these tests to furnish special information that the clinician needs. Another investigation that our laboratory has conducted over a period of ten years is that of blood transfusions controlled by blood grouping as worked out by Moss. At first defibrinated blood was used, then citrated blood, and, since 1916, whole blood by the Lindemann syringe method. Our series of transfusions now numbers about 2000, and has taught us some valuable lessons which will be embodied soon in a report. Many minor investigations besides have been carried on—the agglutination of the typhoid group by the serums of over 100 nurses after vaccination with the triple vaccine, the agglutination and complement fixation curves of normal rabbits after typhoid vaccination, the technique of the Wassermann test with especial reference to cholesterinized antigens, etc. These researches have been of inestimable value, not only in stimulating interest and relieving the routine of laboratory work, but also in inculcating the scientific spirit in the technicians and developing in them an active desire to avoid errors.

ORGANIZATION AND PERSONNEL OF THE PATHOLOGICAL LABORATORY

The staff of a laboratory should be large enough to take care of each piece of work that comes to it at the "peak load" as well as if it were the only work to be done, and this regardless of the overhead cost. Laboratory work takes time and care; it cannot be unduly hurried, and the scientific spirit is brutally injured when one attempts to "get by" with work not well done and well controlled. This ideal requires not only a large staff, but one carefully picked and trained. A laboratory should not accept the training or take the spirit for granted of any technician without a period of probation and careful supervision, no matter where the training has been conducted or how glowing the recommendations. This policy has saved us from many experiences that would have been fraught with distressing errors. An efficient large clinical laboratory must be built up slowly, its efficiency and spirit must be the result of a healthy growth, and beneath all its work should be a supporting tradition of service. These things cannot spring into being with a mushroom growth over night, but, like the great clinical offices, they must begin with the physician in a small way, and gradually grow into their own. It seems to me that this conception gives the clinical laboratory its rightful place among the great dignified specialties of medicine, and I plead for the fine ethical ideals of the medical profession to be applied to the clinical laboratory, to keep it dignified, to save it from commercialism, and to preserve its scientific spirit. In this way only will the place of pathology be an honorable one, in this way only will scientific and high-minded physicians be stimulated to follow this work, and in this way only will pathology be able to give of its best to the practice of medicine and find its place among its sister specialties.

American Red Cross (Abstract from the Report of the Board of Trustees, American Medical Association, Minutes, House of Delegates)—At our annual meeting in November, 1921, the secretary of the board reported the result of a conference with the vice-chairman of the Central Committee of the American Red Cross, in regard to the present and proposed future activities of that organization in public health work. He also presented a copy of a letter written by him to the vice-chairman of the Central Committee of the American Red Cross, in which the opinion was expressed that the time had arrived when the American Red Cross should cease its public health activities and should restrict its work to the relief of disabled ex-service men in the hospitals and in their homes, in addition to the purposes for which it was originally organized, as designated in its charter. The board approved the action of the secretary and endorsed the opinions expressed by him in the letter referred to. Apparently, the Central Committee of the American Red Cross has not modified its public health program. It is the opinion of the board that the association, through the House of Delegates, should take appropriate action to convince those in authority that the public health activities of the American Red Cross are no longer necessary and if continued are likely to promote community irresponsibility and helplessness in regard to its own welfare.—Journal A. M. A., May 27, 1922.

EDITORIALS

THE FIFTY-FIRST ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

The 1922 meeting of the Medical Society of the State of California, held in Yosemite Valley, May 15 to 18, was a success. This from whatever angle one cares to review it.

Socially, the spirit of good-fellowship, companionship and cordiality was splendid as between members, their families and guests. The hospitality and spirit of co-operation of the officers and staffs of the Government, the hotels and transportation companies, deserved and secured much praise. Many persons visiting the Yosemite Valley for the first time were converted into future friends and patrons of its beauty and hospitality.

In spite of the truly wonderful and varied outdoor attractions that invited one on every side, the attendance at all meetings was gratifying and the program was carried out with but minor changes. The program covered an exceedingly wide range of subjects, including public health, clinical medicine, pathology, research, and medical economics.

Over two hundred papers were read. These manuscripts aggregate over 4000 pages of typewritten matter, or, with the discussions, nearly two million words. Printed in ordinary type this would represent about two volumes the size of Osler's text book on medicine.

The most important feature of these statistics, to our members and to the Editor of the Journal, is that it would take over two years to publish all of these papers in the Journal even if every one of the reading pages in every issue were to be utilized exclusively for the purpose.

It is obvious that the Editorial Staff of the Journal has an arduous task in examining all of these manuscripts, as well as the unpleasant and difficult task of selecting from so many good papers the ones that it is possible to use in the Journal before the next meeting of the Society.

The papers presented, both in the General Sessions and in the fourteen Sections, were unusually good; and consequently, the scientific interest and "atmosphere" was kept upon a high plane throughout the meeting.

The important matters acted upon by the Council and House of Delegates will be considered in the July issue of the Journal.

PATENT MEDICINE FRAUDS INCREASING

The advertising columns of some newspapers are beginning to look like they did before Samuel Hopkins Adams' "Great American Fraud Articles" and before the clean advertising organizations began to be effective.

Taking advantage of the general instability of the social and economic conditions, many of the old frauds that have not been in evidence for many years, as well as many new ones, are taking large space and are making the usual fraudulent claims. The testimonial writer is with us again and many others of the oldtime methods once thought to be destroyed are out again in full force.

The following advertisements illustrate this point:

"Hurry Mother! Even a sick child loves the 'fruity' taste of California 'Fig Syrup.'" Many people have forgotten that "Syrup of Figs" contained 6 per cent of alcohol and that its active principle is not figs but senna, a cheap and well-known drug.

"Pape's Cold Compound" was exposed in nostrums and quackery more than ten years ago, when its analysis showed it to contain: Acetanilid, 1.6 grains (a cheap, powerful and dangerous coal-tar heart depressant); phenolphthalein, 1.8 grains (a well known and cheap laxative); sugar, 8 grains.

Many cheap cocktails of other days that have been exposed and all but forgotten are again advertising. The alcohol content that formerly was printed in exceedingly small type is now carried in a way to be easily read.

THOMAS CLAY EDWARDS

In his presidential address, John H. Graves, among other serious and important messages to the physicians and citizens of California, called particular attention to the duties, responsibilities and importance of the work of the general practitioner.

The same theme ran like a golden thread through the discussions and atmosphere of the Fifty-first Annual Convention of the State Medical Society to such an extent that one distinguished member suggested an editorial on the rediscovery of the family physician.

This happy spirit fittingly prepared the way for the unanimous election of Thomas Clay Edwards as President-elect of the State Society.

Doctor Edwards is from Monterey County, and has been engaged in general practice in the small city of Salinas for nearly forty years.

Health Insurance—Group Medicine (Minutes, House of Delegates, A. M. A., address of Speaker) —Compulsory health insurance never will and never can become an American institution. As our campaign of public education broadens, this fantastic, un-American machination and the fancies of its proponents will fail to arrest legislative attention and consideration or draw unto it public demand and support. There are other forms of medical practice, instigated, conducted and extended by individuals, groups and health and lay agencies that encroach on and mitigate against the interests of the individual doctor. Some of them merit endorsement and support. Others, however, require our emphatic and perhaps drastic denouncement. They are dependent, for success and extension, on the members of our profession. Regretfully we recognize that many physicians, thoughtful only of self, place their services at the command of such agencies. Such practices must not be condoned.—Journal A. M. A., May 27, 1922.

COUNTY SOCIETIES

ALAMEDA COUNTY

Alameda County Medical Association (reported by C. L. McVey, secretary-treasurer)—The general meeting of the Alameda County Medical Association was held on April 17, 1922, at the Public Health Center.

George Rothganger presented a case of infantile paralysis in a boy who has been operated on for correction of the deformity in the lower extremities, resulting from a former infection.

A. A. Alexander read a paper on "Some Common Heart Arrhythmias." Recent development of interest in arrhythmia has led to elaborate instrumental investigation. Basing our efforts upon the material so provided we may diagnose many arrhythmias by simple bedside investigation. Alexander emphasized the importance of recognition of beginnings of diseased state as an aid to restoration; of the anatomy and physiology; of mechanism, etiology and recognition of (1) tachycardia; (2) heart block; (3) auricular flutter; (4) auricular fibrillation.

Mr. P. L. Ansell discussed "The Value of Teleroentgenograms in diseases of the cardio-vascular system. (1) limitation of the fluroscopic method of examination; (2) comparison of the Groedel Bardeen and Friedlander methods of heart measurements and the types of cases in which teleroentgenographic measures are of greatest value as an aid to diagnosis; (3) the value of combining two of the above methods, based on a series of cases in institutional work and private patients.

The Secretary read resolutions of condolence in the case of the death of Joseph Medros. The committee appointed to draw up the resolutions were Maher, U. C. Billingsly and James Hanley.

About twenty-one members of the Merritt Hospital staff made a trip to Fresno on May 2. A banquet was given to the visiting physicians by the staff of the Burnett hospital. The meeting of the Fresno County Medical Association was turned over to the visitors. Hubert Rowell read a paper on "Some Neglected Landmarks in Therapeutics." S. H. Buteau followed with a paper on "The Surgical Abdomen." Siefert read a paper on "X-ray Therapy." M. L. Emerson read a paper on the use of "Novocaine in Spinal Anesthesia."

CONTRA COSTA COUNTY

Cottage Hospital, Richmond, California—This hospital, under the management of Miss Agnes Driscoll, has recently been equipped with an electric sterilizing outfit.

VENTURA COUNTY

Big Sisters Hosital, Ventura—What was formerly known as the Bard Memorial Hospital is now known as the Big Sisters Hospital. It has a board of directors representing the Big Sisters organization, and its staff includes practically all of the members of the Ventura County Medical Society. Miss Mary Ferdinand, an experienced nurse, is superintendent of the hospital.

FRESNO COUNTY

Selma Sanitarium, Selma—This new hospital is nearing completion. The building consists of a half basement and first and second floors, with the usual space for general utility departments and office administration.

KERN COUNTY

Wasco Sanitarium—E. S. Fogg is erecting a small sanitarium near his office in Wasco, Kern County. The sanitarium will consist of five rooms and is connected with Dr. Fogg's office.

LOS ANGELES COUNTY

The Los Angeles Radium and Oncologic Institute Opens Clinic For Those Unable to Pay—With the installation of the new deep X-ray therapy equipment and otherwise increasing the personnel and facilities of the Institute, the directors feel that it is desirable to establish a definite clinic for the study and treatment of appropriate indigent patients. There has been set aside approximately one-fourth of the facilities of the Radium, X-ray and Clinical laboratories to be devoted to this work. The clinic will be limited to ambulatory cases and will be conducted on Wednesday and Saturday mornings, from 9 to 10 o'clock. Members of the medical profession are cordially invited to visit the clinic that they may better familiarize themselves with the development of radiology and the diagnosis and treatment of neoplastic diseases and other appropriate conditions (Bulletin, Los Angeles County Medical Association, February 16, 1922).

Hollywood Community Hospital—This organization now owns its own lot and has $245,000. They are going ahead with their plans to build in proportion to the total amount of money received by the selling of preferred stock with a guaranteed interest of 7 per cent and now earning common stock. Shareholders in both classes of stock have a say in the management of the institution. It is proposed that this hospital make the usual charges for service to those who are able to pay; those who cannot pay full rates shall pay as much as they can afford, even though this may be nothing at all. The balance in volume between full pay, part pay and absolutely free work will be maintained in accordance with the condition of the hospital's finances, it not being essentially a money-making proposition.

Long Beach Municipal Hospital—A movement is under way by the city of Long Beach to convert its present city hall into a municipal emergency hospital when the new city hall, now under construction, is completed.

Hermosa Beach—The Hermosa Beach and Redondo Beach Chambers of Commerce have endorsed the proposition of Carl Anderson, M. D., to open a sanitarium. Local physicians of Hermosa Beach have endorsed Dr. Anderson's plan for a general hospital.

Casa Del Mar Hospital, Venice—This hospital consists of twenty modern bungalows that will take care of three patients each, with a central general utility service arranged somewhat like the bungalow hotels of Southern California. The hospital is located on Venice boulevard, easily accessible to all parts of the Santa Monica bay district.

El Segundo Hospital—Mrs. Gregory has opened a five-bed hospital at El Segundo, California. The staff of the hospital consists of Doctors Harry H. Davis and C. M. Anderson of Hermosa Beach.

Good Samaritan Hospital, Los Angeles—This hospital has recently been accredited by the Council on Medical Education and Hospitals of the A. M. A. This is gratifying news to all medical men in the southern part of the State, and the Board of Trustees, officers and staff of that hospital are to be congratulated upon the splendid improvement they have made in the hospital during the last few years.

Children's Hospital, Los Angeles—The outpatient department of this splendid hospital is growing very rapidly. Last year the combined clinics handled 6,674 patients.

Los Angeles Orthopedic Hospital and School—This new hospital, costing $150,000, was dedicated and opened to the public on April 17, 1922. The hospital and school will be operated by the Los Angeles Orthopedic Foundation. The beautiful

property on which the hospital is located was given by Mr. John Brockman, and Mrs. Anita Baldwin contributed $50,000 of the cost of the building and equipment. Twelve thousand people have contributed small amounts, and more than four hundred of them were present at the opening exercises. Dr. C. L. Lowman is director of the institution.

MERCED COUNTY

New Method of Selecting Physician—The Merced Board of Irrigation has passed a resolution to ask physicians to submit their names for a one-dollar-a-month contract practice among the employes of the district, and to care for sicknesses that may arise in their various camps. The method of selecting is, to put the names of the various physicians (if any should so lower their standing as to apply) in a hat and shake it. Then a name will be drawn from the hat, and the physician whose name is drawn will be declared the official physician of the Merced Board of Irrigation. This is a particularly disgusting reflection upon the medical profession and, as one of our reporters from Merced County states, "It has all the earmarks of shaking dice for cigars."

RIVERSIDE COUNTY

Riverside County Medical Society (reported by T. A. Card, secretary)—The County Medical Society met at the Mission Inn on April 10, 1922, with 35 members and 25 visitors present and 12 members absent. The occasion of the meeting was a complimentary dinner to President Ray Lyman Wilbur of Stanford University, given by the Board of Directors of the Riverside Community Hospital.

President Wilbur's subject at the meeting was "The Community Function of the Hospital." Dr. Wilbur stated that "the hospital is primarily the training center for health in a community. It is a real community enterprise, even though conducted on an independent basis by private individuals. The application of aseptic surgery, the contributions of the laboratory sciences to medical practice, the X-ray, etc., have all demanded a center in which they may operate to the economical service advantage of all the people. Such a hospital is also the radiating point for medical information. It is here that the physician, the student, the nurse, the patient and the public all come together with a common purpose. Community welfare depends upon the physician more than upon the politician."

Dr. E. N. Wood, superintendent of the County Hospital, has been granted leave of absence for one year, and A. W. Jones will occupy the office of superintendent during this period.

Hemet Hospital—J. A. Ramsay, M. D., has assumed control of Hillcrest Sanitarium at Hemet, relieving Dr. Gregory, who formerly had charge of the institution.

SANTA CLARA COUNTY

Santa Clara County Medical Society (reported by E. P. Cook, secretary)—The Santa Clara County Medical Society, the County Dental Society and the Bar Association of Santa Clara County held a joint meeting on April 19 in the banquet hall of the Commercial Club at San Jose. Samuel G. Tomkins, president of the new San Jose Hospital board of directors, presided. Short talks were given by George B. Little, president of the County Dental Association; Raymond C. Wayland, president of the County Medical Society; Hon. John E. Richards, Judge of the Appellate Court of California, and James B. Bullitt.

[Editor's Note—The Santa Clara County Medical Society is to be congraulated upon its activities and particularly upon initiating this form of meeting between members of three great professions.]

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—The society met at the County Hospital, San Bernardino, with thirty members, twenty dentists and ten guests present, and forty members absent.

George W. Clark and J. S. Reekie were elected to membership. Charles P. Engel transferred from Calexico.

Goodman A. Miller, D. D. S., presented a paper on "Radiographic History of a Case of Osteomyelitis of Entire Mandible."

William B. Bowman of Los Angeles discussed "Fractured Vertebrae," and Ellis Jones of Los Angeles discussed the "Treatment of Club Feet."

This was an interesting combination meeting of the Medical and Dental Societies and scientific problems of common interest were discussed by both organizations.

Health and Medical Work in San Bernardino County—San Bernardino County has adopted the best method possible as a nucleus upon which a program of public health and medical improvement can be based. They have combined the positions of county health officer, county physician and superintendent of the county hospital into one position and have employed upon a strictly full-time basis a physician, Dr. Lenker, to fill these three positions.

They have furthermore placed upon salary an assistant to Dr. Lenker upon full time, Dr. Vickers.

SAN DIEGO COUNTY

San Diego County Medical Society (reported by Robert Pollock)—The physicians of San Diego are considering an opportunity to enjoy their own building with the space devoted entirely to offices of physicians and dentists and tenants acceptable to them. Ground will be broken within a month for a six-story building facing on Fifth, Sixth and B streets, to contain a theater entrance and store rooms on the ground floor, and offices on the floors above. The owners are willing to make of it a physicians' building and name it such, provided 80 per cent of the floor space will be contracted for. The location is an ideal one, situated in the heart of the shopping district. The owners, as we understand, are willing also to provide free of rental a library room and auditorium for the medical and dental societies. It reflects the fact that the members of these professions make good and permanent tenants.

The San Diego Society is sending a good delegation to the Yosemite meeting of the State Society.

The last meeting of the County Medical Society was held in the auditorium at St. Joseph's Hospital on Tuesday, April 25, and discussed as the paper of the evening the treatment of asthma in all its bearings. The essayist was R. A. Kocher.

The newly installed staff of the San Diego County General Hospital consists of the following: Samuel Stallard, University of Virginia; E. O. Rowley, University of New Zealand; Gladys Rowley, University of New Zealand; Gwendolyn Stewart, College of Medical Evangelista, Loma Linda and Los Angeles.

In the passing of Dr. E. M. Fly, the San Diego profession and the county society lost a much valued member; one whose counsels were ever soght and prized in times of public crises when the well-trained and experienced medical man alone could guide and guard the public health. The Bulletin hopes in the near future to present a brief biography of our lamented brother. Meanwhile the Bulletin anticipates the action of the society in properly recording in its own transactions the sense of the loss it has sustained.—R. P. (Bulletin of the San Diego County Medical Society.)

SAN FRANCISCO COUNTY

San Francisco County Medical Society—At the meeting of April 18, E. B. Towne read a paper on the value of cerebral pneumograms in the localization of intracranial lesions. He reviewed Dandy's work, and presented five illustrative case reports.

In three cases of obstructive hydrocephalus from 500 to 1500 cc. of ventricular fluid were replaced by air. Roentgenograms of the infants' heads showed the disease to be due to occlusion of (1) the foramina of Magendie and Luschka, (2) the aqueduct of Sylvius, and (3) the right foramen of Monro. New foramina were made for the first two patients, but, though the operations were well borne, the hydrocephalus was not cured, and both died in a few weeks. The third patient died of shock following extirpation of the choroid plexus. In these three cases the disease was far advanced; Dandy has shown that before the ventricles are greatly dilated the points of obstruction can be attacked with a fair chance of success.

The two brain tumor cases were more important. The first patient had increased intracranial pressure and major epilepsy, without localizing signs. The pneumogram showed that no air passed into the left lateral ventricle. At operation a large gliomatous cyst in the left temporal lobe was evacuated. Six months later the patient was working and considered herself perfectly well. In the second case major epilepsy began in the thirty-second year, without increased intracranial pressure or localizing signs. Roentgenograms disclosed a calcified tumor in the right frontal lobe. Pneumograms were done to try to demonstrate whether the tumor was attached to the meninges at the base or lateral wall; but they gave no help, for no air passed into the right lateral ventricle. At operation a calcified glioma was partially removed. Three months later the patient was having occasional epileptic attacks. Had the tumor not been calcified it could have been diagnosed only by the pneumogram. Such patients are probably not infrequently treated as cases of idiopathic epilepsy.

The conclusions were that cerebral pneumography was devoid of harmful effects in these five cases; that it was valuable in detecting the point of occlusion in obstructive hydrocephalus; and that it was the essential diagnostic method in the localization of tumors lying in silent areas of the brain.

City Board of Health Budget—The City Board of Health budget for the coming fiscal year has been submitted and totals $4,000,000. This budget includes $15,000 for radium, $11,000 for a building to house women discharged from State institutions, $1,500,000 for new buildings at the Relief Home, and $500,000 for a new Board of Health building.

University of California Student Hospital—The present "Infirmary," located on the campus of the University at Berkeley, has been declared inadequate, and plans are under way to construct a new hospital of 100 beds, to be used by faculties and students of the university. Robert T. Legge, M. D., is director of this hospital.

St. Luke's Hospital—St. Luke's Hospital, San Francisco, announces that it is now equipped with a modern deep therapy X-ray apparatus which has ability to produce a voltage of 280,000 volts.

Dr. Alfred C. Reed has resigned as medical director of the Ross Sanitarium.

SOLANO COUNTY

Benicia Arsenal Hospital—Money has been appropriated and plans and specifications are being prepared for the construction of a hospital in Benicia Arsenal.

SAN JOAQUIN COUNTY

San Joaquin County Medical Society (reported by Dewey R. Powell, secretary)—The regular meeting of the San Joaquin County Medical Society was held at the State Hospital Friday evening, April 14. In the absence of the president, Margaret Smythe, second vice-president, presided. Those present were: Margaret Smythe, L. Dozier, Grace McCoskey, F. J. Conzelman, E. L. Blackmun, H. C. Price, H. E. Sanderson, J. W. Barnes, W. Friedberger, E. L. Tretheway, J. E. Nels, E. A. Arthur, A. H. McLeish, N. E. Williamson, C. D. Holliger, J. P. Hull, H. Smythe, D. R. Powell, with W. H. Kellogg and E. C. Dickson of San Francisco as guests.

The first paper was given by E. C. Dickson on the subject of "Botulism." He spoke of the recent interest through the outbreak three years ago in the east which was due to California ripe olives and resulted in widespread newspaper publicity which crippled the olive business for a period of two years. As a matter of fact botulism was well described in 1735 and in 1802 was the subject of public health reports in German cities.

The bacillus botulinus is a spore bearer and an anaerobe and withstands 245 degrees heat for 35 minutes. Furthermore its toxin is not destroyed by gastric juices. The bacteria do not produce toxin in the body but it develops in preserved food before eating. He showed the small proportion of infected cans in 1917, 1918 and 1920 by stating that out of 91,912,000 cans of olives fourteen cans only were known to have been infected. Since 1889 not over 200 jars of all kinds of preserved food have been known to have been infected and in 1917 alone 850,000,000 home-canned containers for home-canned materials were sold. Preventive measures have been established by care on the part of the commercial canner under Government regulations together with the education of the individual housewife through public channels. During the discussion Dickson answered many questions and spoke of some of the symptoms. In the first twenty-four hours there is general malaise, double vision, dizziness. In thirty hours ptosis, dilated pupil, paralysis in talking and swallowing, muscle weakness, no pain, no sensory disturbances, death from respiratory failure and the mortality is from 60 per cent to 100 per cent. Clinically the use of antitoxin has been disappointing because not given early enough.

The next speaker was W. H. Kellogg, who spoke on the control of diphtheria. He mentioned the decrease in the mortality rate from 64 per cent to around 8 or 10 per cent with use of antitoxin, but that there are still about 200,000 cases per year with some 20,000 deaths. The main method of spreading the disease is by the healthy carrier or by the case in which the diagnosis has been missed. Most of the deaths are due to the delay in calling help, and Kellogg emphasized the necessity of giving antitoxin early without waiting for a laboratory report in suspicious cases and of giving adequate initial doses, wherever possible, intravenously. In the control of diphtheria the matter of educating the public to be suspicious of sore throats and care for them early was emphasized as well as establishing immunity by toxin antitoxin method. Over 100,000 such cases have been treated in New York City with no bad results. This test is of great importance to children as the older one gets the more immunity is established. Kellogg also mentioned a test he is using. This consists in injecting the blood of a guinea pig which in cases of a susceptible patient gives a very quick reaction in a few hours; quicker results than the Schick test. Numerous questions were answered and the chairman thanked both physicians for their courtesy in appearing before the society.

Second meeting of Medical Society (reported by D. R. Powell, secretary)—The meeting of May 12 of the San Joaquin County Medical Society was held at the State Hospital. Those present were: R. T. McGurk, J. D. Dameron, A. H. McLeish, F. P. Clark, H. Smythe, Minerva Goodman, F. J. Conzelman, H. E. Sanderson, Grace McCoskey, Margaret Smythe, N. E. Williamson, L. Dozier, H. S. Chapman, C. F. English, D. R. Powell, and Kaplan of Stockton, with Richard W. Harvey and Julian M. Wolfsohn of San Francisco as guests.

The following resolution was unanimously adopted:

Whereas, the State hospitals for the insane and the Sonoma State Home for Feeble-minded comprise the medical division of the State's service; and

Whereas, we feel that the care and supervision of these institutions should be under the direction of a medical man; and

Whereas, Dr. John A. Reily, former Medical Superintendent of the Patton State Hospital, has been appointed to the position of Director of State Institutions; and

Whereas, on account of Dr. Reily's long and efficient service in the care and management of the insane, we are confident that the departments of the State's service under his jurisdiction will be conducted in an efficient and economical manner; be it

Resolved, that the San Joaquin County Medical Society at this meeting on May 12 commend Hon. William D. Stephens, Governor of the State of California, for appointing Dr. Reily; and be it further

Resolved, that a copy of this resolution be forwarded to Governor Stephens.

The delegate to the California State Medical Society meeting in Yosemite Valley was instructed to introduce such resolution at the State meeting.

A motion was adopted instructing the secretary to write to the District Attorney and Assistant District Attorney, expressing the approval of the society over the diligent action of the officials in prosecuting individuals who are practicing medicine without a license.

Dr. Richard W. Harvey of San Francisco read a paper on "Combined System Disease." Harvey discussed very thoroughly the etiology, symptoms, differential diagnosis and pathological findings.

Julian M. Wolfsohn spoke on the "Clinical and Pathological Aspects of Lethargic Encephalitis." The author particularly emphasized the fact that lethargic encephalitis was an infection of the central nervous system of unknown origin and that the prognosis must be extremely guarded. Cure is not certain and relapses occur very easily and frequently and the only treatment is rest in bed over a minimum period of two months followed by another period of no work for six or eight months.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by A. C. Soper, Jr., Secretary)—The County Society held two meetings in April; one on the 10th with fifteen members and one visitor present and thirty-nine members absent; the other on the 24th with twenty-six members and three visitors present and twenty-eight members absent.

Albert Quincy Spaulding of Santa Barbara was elected to membership. Application of Jesse P. Truax of Lompoc was referred to the censors.

The society passed a unanimous resolution recommending that the City Council pass a resolution insuring a sane and safe Fourth of July.

H. O. Koefod read a paper on "Perforating Aneurysm of the Abdominal Aorta."

G. F. Farman, paper, presented by H. J. Profant, was on "The First 100 Cases Examined at the Santa Barbara Boys' Clinic."

The society invited Dr. Geiger of the U. S. Public Health Service to give a public lecture in Santa Barbara on "Botulism."

At the meeting on April 24, R. M. Clarke presented a paper on "Treatment of Constipation." This paper elicited considerable discussion by many members.

H. J. Profant read a paper on "Suppurative Parotitis," which consisted of a critical review of literature.

Santa Maria Valley Hospital Association—This group association has been authorized to sell stock and to proceed with the construction of the Santa Maria Hospital. Lucas, Thorner, and Coblentz are the prime movers in this laudable ambition to secure a good hospital for Santa Maria.

Cottage Hospital, Santa Barbara—This hospital has now completed the installation of a modern deep therapy X-ray department. The apparatus is capable of developing 280,000 volts, of which 200,000 volts are available.

YOLO COUNTY

Yolo County Medical Society (reported by Lela J. Beebe, secretary)—This report covers the meettings and activities of the society for March, April and May.

The society met on March 14 at the County Court House, Woodland. Those present were Bates, Beebe, F. R. Fairchild, Lawhead, Lawson, Goffin and Newton. Absent: Bransford, Craig, Desrosier, C. H. Fairchild, King, McManus, Parsons, Poage, Pulsifer and Ward.

Crawford of Sacramento read a paper on "Some Orthopedic Defects of Common Occurrence."

J. D. Lawson of Woodland and Keith of Williams were elected to membership.

Goffin, Blevins and Lawhead were elected to the Board of Censors.

Lawhead was appointed delegate to the State meeting in May.

W. E. Bates and H. D. Lawhead presented reports of their observations while attending the recent Medical Clinics at Rochester, Minn.

The Woodland Sanitarium has now available 65 mg. radium, which will be put to use at once.

The Woodland Sanitarium reports that, since its weekly Health Conferences for children were opened in February, 1921, 342 children under six and 92 children of school age have been given a physical examination here with recommendations regarding hygiene and correction of defects. Frequent return of these children for observation have brought the total of visits during this time up to 1100.

SONOMA COUNTY

Sonoma County Medical Society (reported by N. Juell, Secretary)—The monthly meeting of the Sonoma County Medical Society was held on April 22 with nine members and two visitors present and twenty-nine members absent.

A number of interesting case reports were discussed at the meeting.

TULARE COUNTY

Tulare County Medical Society (reported by Elmo R. Zumwalt, secretary)—Tulare County Medical Society met on Sunday, April 23, 1922, at Hotel Johnson, Visalia. Following dinner the meeting was called to order by President A. W. Preston. There were twenty-two members present.

Following a few business items the speaker of the evening Miley Wesson of San Francisco gave a most interesting talk on the embryology of the bladder in its relation to present day diseases with especial reference to prostatic hypertrophy. The talk was enhanced by a series of excellent lantern slides.

C. A. Tillotson, M. D., of Dinuba, announced his candidacy at the coming primaries as a candidate for the State Assembly. Dr. Tillotson is a man who will fill such a position most capably and should receive the hearty support of the whole district.

Pharmacy and Chemistry

Edited by FELIX LENGFELD, Ph. D.

Help the propaganda for reform by prescribing official preparations. The committees of the U. S. P. and N. F. are chosen from the very best therapeutists, pharmacologists, pharmacognosists and pharmacists. The formulae are carefully worked out and the products tested in scientifically equipped laboratories under the very best conditions. Is it not plausible to assume that these preparations are, at least, as good as those evolved with far inferior facilities by the mercenary nostrum maker who claims all the law will allow?

Quinidin in Heart Disease—Quinidin has suddenly leaped into prominence because of its striking effects in certain forms of cardiac irregularity. To see a heart that has been constantly irregular for one or two years because of a fibrillating auricle lose its lawless and rapid beat within a few hours under the influence of this drug and resume normal rhythm and rate and maintain these for months, must attract the attention of all. The conclusions of the few clinicians who have thus far reported their investigations are in remarkable agreement as to the fact that in about half of the cases of auricular fibrillation, Quinidin is capable of restoring to the sino-auricular node the control of the heart so that, for a time at least, the working of the heart is normal. However, while those who report on the effects of Quinidin are fascinated by the possibilities of the application of this drug in medicine, they are wisely conservative in their statements and frankly admit that much is yet to be learned concerning its proper use. It is to be hoped that the few favorable reports will not lead to the indiscriminate use of the drug in every type of irregular and rapid type of heart (Journal A. M. A., December 3, 1921, page 1822).

Delano's Rheumatic Conqueror has had quite a vogue in some parts of the country and has even been prescribed by physicians. Analysis shows that it consists of starch, talc, chalk and a little quinine.

Butyn is a new local anesthetic which may, if its claims are verified, advantageously take the place of cocain in many eye cases. It is a chemical individual, and not a secret preparation, but has not yet been accepted by the Council simply because that body thinks the clinical work is not yet sufficient to justify its acceptance. It seems worthy of clinical trial, which alone will tell the tale, and may easily be obtained by any physician who cares to try it.

Intravenous Specialties—There sprung up all over the country a number of concerns making specialties and standard preparations for hypodermatic and intravenous use. Some of these concerns are undoubtedly honest and are getting out good preparations. Some are honest and competent and others are simply exploiting the medical profession and the public. Physicians should be particularly careful about using these preparations and should see that the manufacturer is thoroughly reputable and not simply a "fly-by-night" with a sleek detail man. There is always a certain amount of danger in giving even the best of any of these preparations, and patients who suffer an abscess occasionally threaten the physician with a malpractice suit. The best defense in such a case would be the reputation of the house making the ampoule.

Cod Liver Oil seems to be coming into its own again. This old household remedy was for a while discredited by most physicians who believed its sole value that of a food and therefore that it could be replaced by more palatable oils. The recent work on vitamines and the discovery that Cod Liver Oil is particularly rich in at least one of them has placed it back in favor. Its value in rickets has now been definitely proved by Park and Howland who took roentgenograms which show definitely that it will cure ricketts if the diet is not otherwise too faulty. In this connection it may be stated that some other experiments seem to indicate that ricketts can be cured by plenty of sunlight. Perhaps we have the mysterious vitamines acting in the one and the electron in the other.

Esters of the fatty acid of **chaulmoogra oil** are now marketed under the name of Chaulmestrol. This is a distinct advantage because the physician who has not a chemical laboratory at his disposal can now try this remedy.

Nuforal is a name of another alleged tuberculosis remedy now on the market for revenue only.

Sodium sulphate is one of the best antidotes for **phenol poisoning.** Alcohol, which has been largely accepted as an antidote, does more harm than good when taken into the stomach.

In many parts of the country the law requires the addition of alcohol to the solution of phenol before it can be sold indiscriminately. This seems a mistake as the alcohol probably makes it more easily miscible with the contents of the stomach and, therefore, more easily absorbed. Washing with alcohol does undoubtedly prevent the local escharotic action of phenol and if applied immediately prevents carbolic acid burns. Its action is probably that of a solvent and other solvents may do as well though there seems to be no experimental work on this subject.

Another wide-spread fallacy is the belief that no water must be applied to a **sulphuric acid burn** as the water will simply cause the evolution of heat and, therefore, intensify the burn. This may be so if only a small quantity of water is used but if a large quantity be used the sulphuric acid is diluted and washed away and the heat involved is negligible as compared with the cooling effect of the water.

The writer knows of at least one instance where a trifling sulphuric acid burn became rather serious because nothing at all was done for ten or fifteen minutes while waiting for bicarbonate of soda and oil. The addition of bicarbonate of soda evolves more heat than does the addition of water. Another fact not generally known is that low-boiling gasoline acts on bromine just as alcohol does on carbolic acid, so that if bromine be spilled on the skin no bad results will be noticed if the place be immediately thoroughly washed with gasoline.

Another Step Toward Free Medical Care for Everybody—According to the New York Post of March 29, the United States Government is conducting a public service clinic at 67 Hudson street, New York. This clinic is not only open to all Federal employes, but is also open to all civil service employes of the city of New York.

In spite of the fact that this clinic is expensively equipped and expensively maintained, it has been found necessary to secure newspaper publicity in order to get patients.

Clinics of this character cause further confusion in the minds of the public as to what is worth while in medicine.

New Director for State Department of Institutions—Mr. Ralph Fisher has resigned from this position and John A. Reily, M. D., formerly medical superintendent of the Southern California State Hospital, has been appointed to fill this important medical position.

EXTENSION WORK

The following additions have been made to the Extension Lecture courses offered by members of the State Society to local societies: (See November, February and March Journals for other lectures.)

MAX ROTHSCHILD,

350 Post Street, San Francisco.

1. The early diagnosis of lung diseases.
   With especial reference to X-ray and fluroscopic examinations, and to immune-biological tests.
2. The diagnosis and treatment of tuberculosis of bronchial glands in children.
   Demonstration of X-rays showing normal and pathological conditions in children. Discussion of specific and non-specific as well as symptomatic treatment.
3. The problem of immunity in tuberculosis.
   Discussion of different theories regarding this problem, with especial reference to the laws of immunity which have been established and generally accepted.
4. The treatment of tuberculosis with specific remedies.
   Description of the vaccines and sera usually administered. A modern classification of pathological conditions which forms the basis of determination for treatment. Demonstration of X-ray plates of cases treated.
5. The treatment of tuberculosis with non-specific remedies, with especial reference to preumothorax treatment.
   Discussion of dietetic and hygienic and general treatment, heliotherapy, artificial light, X-ray treatment, pneumothorax and thoracoplasty. Demonstration of X-ray plates of cases treated.

WM. C. VOORSANGER,

177 Post Street, San Francisco.

1. Pulmonary conditions wrongly diagnosed as Tuberculosis.
2. Tuberculous Laryngitis—Is It Curable? Heliotherapy as a remedy.
3. Gastro-Intestinal Complications in Pulmonary Tuberculosis.
   1. Functional.
   2. Organic.
   3. The use of Calcium Chloride intrevenously to allay abdominal pain and inhibit peristalsis.
4. Artificial Pneumo-thorax in the treatment of Pulmonary Tuberculosis.
5. What do tuberculin and vaccines really accomplish in the treatment of pulmonary tuberculosis?
6. Advances in the diagnosis of pulmonary tuberculosis.

EDWIN I. BARTLETT, M. D.,

291 Geary Street, San Francisco.

1. Diagnosis of malignant condition by means of the exploratory incision.
   This is a lantern slide lecture dealing with the scope of the exploratory with special application to breast conditions.
   There is a discussion of when to explore, how to explore, how to interpret the findings and how to handle the case after the diagnosis is made.
2. Tumors of the mouth and jaw.
   This is an illustrated lecture dealing with differential diagnosis—treatment and prognosis.
3. Bone tumors.
   A discussion of clinical and X-ray pictures, with special reference to differential diagnosis and treatment.

Diet for Bald-heads—Now comes a New Jersey doctor with a diet for bald-headed men. He tells them that criniculture is a matter of eating some things and refraining from eating others, and that a man can have as much thatch as he wishes if he is prepared to go on a diet. It is much like telling little boys and girls that they can have curly hair if they will eat their crusts.

But there is a serious and California side to the New Jersey doctor's bill of fare for the bald. In his list of seven aids to decorating the human dome with abundant foliage he includes prunes, raisins and oranges—all fruits for which California is famous. If his advice is taken then every day will be a raisin day and a prune day and day of the sun-kissed orange, and California's industries will boom as never before. The people of the prune and raisin belts should award the New Jersey doctor a gold medal (American Registered Pharmacist's Journal, February, 1922).

BOOKS RECEIVED

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for review in the interests of our readers and as space permits.

Diseases of the Skin and the Eruptive Fevers. By Jay Frank Schamberg, M. D., Professor of Dermatology and Syphilis, Graduate School of Medicine, University of Pennsylvania. Fourth edition thoroughly revised. Octavo of 626 pages, 265 illustrations. Philadelphia and London: W. B. Saunders Company, 1921. Cloth, $5 net.

The Medical Interpreter. A digest in four numbers. The interpretation and translation of the world's practical medicine and surgery. Illustrated. Domestic and foreign. By Albert Alleman, A. B., M. D.

The Submucous Resection of the Nasal Septum. By W. Meddaugh Dunning, Consulting Otologist, Fordham Hospital, New York City. New York Surgery Publishing Company. 1921.

Ephraim McDowell. "Father of Ovariotomy" and founder of abdominal surgery. With an appendix on Jane Todd Crawford. By August Schachner, M. D., F. A. C. S. Philadelphia and London: J. B. Lippincott Company.

Abdominal Pain. By Prof. Dr. Norbert Ortner, Chief of the Second Medical Clinic at the University of Vienna. Authorized translation by William A. Brams, M. D., formerly Lieutenant Commander Medical Corps, U. S. N., and Dr. Alfred P. Luger, First Assistant, Second Medical Clinic, University of Vienna. New York: Rebman Company. 1922.

Epidemiology and Public Health. A text and reference book for physicians, medical students and health workers. In three volumes. By Victor C. Vaughan, M. D., LL. D., Assisted by Henry F. Vaughan, M. S., Ph. D., and George T. Palmer, M. S., Ph. D. Vol. 1, Respiratory Infections. St. Louis: C. V. Mosby Company. 1922.

Papers from the Mayo Foundation for Medical Education and Research and the Graduate School of Medicine of the University of Minnesota, covering the period of 1915-1920. Octavo volume of 695 pages with 203 illustrations. Philadelphia and London: W. B. Saunders Company, 1921. Cloth, $10 net.

Nutrition and Growth in Children, by William R. P. Emerson, A. B., M. D. 340 pages. Illustrated. New York and London: D. Appleton & Company, 1922.

The Vitamins, by H. C. Sherman, Professor of Food Chemistry, Columbia Unversity, and S. L. Smith, Specialist in Biological and Food Chemistry, United States Department of Agriculture. American Chemical Society Monograph Series. New York: The Chemical Catalog Company. 1922.

Basal Metabolism: Its Determination and Application. Frank B. Sanborn, M. S., Editor. Boston: Sanborn Company. 1922.

Pathogenic Micro-organisms—A practical manual for students, physicians, and health officers. By William Hallock Park, M. D., and Anna Wessels William, M. D., assisted by Charles Krumwiede, Jr., M. D. Seventh edition, enlarged and thoroughly revised. With 214 engravings and nine full-page plates. 786 pages. Philadelphia and New York: Lee & Febiger. 1920.

Practical Treatise on Diseases of the Skin—For the use of students and practitioners. By Oliver S. Ormsby, M. D. Second edition, thoroughly revised. Illustrated with 445 engravings and four plates in colors and monochrome. 1166 pages. Philadelphia and New York: Lea and Febiger. 1921.

Experimental Pharmacology—By Hugh McGuigan, Ph. D., M. D. Illustrated with 56 engravings and seven colored plates. Philadelphia and New York: Lea & Febiger. 1919.

Symptoms in the Diagnosis of Disease—By Hobart Amory Hare, M. D., B. Sc. Eighth edition, thoroughtly revised. Illustrated with 195 engravings and nine plates. Philadelphia and New York: Lea & Febiger. 1920.

Pitfalls—By A. J. Caffrey, M. D., instructor in physiology at Milwaukee Medical College from 1901 to 1910. Assistant Professor of Medicine at Marquette University School of Medicine from 1913 to 1920. Boston: Richard G. Badger, the Gorham Press. 1921.

Surgical Treatment of Non-Malignant Affections of the Stomach—By Charles Greene Cumston, M. D., and George Patry, M. D. Lecturers at at the University of Geneva and members of the Surgical Society of Switzerland. With an introduction by Sir Berkeley G. A. Moynihan, K. C. M. G., C. B., M. S., Professor of Clinical Surgery, University of Leeds. Philadelphia: J. B. Lippincott Company. Price, $5.

Tuberculosis in Infancy and Childhood—By J. Claxton Gittings, M. D., and Frank Crozer Knowles, M. D., and Astley P. C. Ashhurst, M. D. Illustrated. 273 pages. Philadelphia and London: J. B. Lippincott Company. 1922. Price, $5.

Skin and Venereal Diseases (Practical Medicine Series)—Edited by Oliver S. Ormsby, M. D., and James Herbert Mitchell, M. D. Vol. 7, Series 1921. 243 pages. Chicago: The Year Book Publishers. Price, $1.75.

Nervous and Mental Diseases (Practical Medicine Series)—Edited by Peter Bassoe, M. D. Vol. 8, Series 1921. 249 pages. Chicago: The Year Book Publishers. Price, $1.75.

An Essay on the Physiology of Mind, by Francis X. Dercum, M. D., Ph. D., Professor of Nervous and Mental Diseases in the Jefferson Medical College, Philadelhpia. 12mo of 150 pages. Philadelphia and London: W. B. Saunders Company. 1922. Cloth, $1.75 net.

New Medical Superintendent for Southern California State Hospital—Edwin Wayte, M. D., has been appointed medical superintendent of the Southern California State Hospital, to fill the vacancy caused by the promotion of John A. Reily, the former superintendent, to the position of director of the Department of Institutions of the State of California.

BOOK REVIEWS

Mechanics of the Digestive Tract—By Walter C. Alvarez. New York: Paul B. Hoeber. 1922.

An admirable book. Altogether admirable if in reading the chapters in which the author draws clinical conclusions from his laboratory experiments one will revert to the preface "and emphasize the fact that much of what is written in Chapters IX and X is purely suggestive."

Alvarez has carried out successfully a difficult task—that of writing a record of laboratory experiments for clinicians and practitioners to read. It takes an extraordinary man to combine laboratory and practice; one at once, as Alvarez is, a scientist and a clinician. There are very few Americans who have done this, or who could do it. The English have. This kind of work seems to go with what is best in the English mind, with a mind simple, logical, comprehending and comprehensive—such as Hunter's or Mackenzie's, Horsley's and Keith's—to name but a few of the best. The American prefers, or is able to follow but one of two courses: either to immure himself with a frog and a kymograph in a laboratory or to tear about from patient to patient in a motor car. Ability to combine the two kinds of activity is given to very few.

Let us hope, Dr. Alvarez, that your book may lead others on. There are hopes in the younger generation that it may fall here and there on fruitful ground. That many of the older men may follow it, or even trouble to lay down the Saturday Evening Post in order to read it, seems pretty hopeless.

Whether one entirely agrees with the book or not, especially whether the deductive chapters have not gone too far, is another question. We should like to see uremic hiccups and the sudden violent ileus following kidney operations explained in this chapter.

The make-up of the book evidences the author's care and good taste. The typography is excellent. The bibliography is a model. The references are culled from the diversest sources, chemical, botanical, and zoological; old and new; yet they are not diffuse but bear exactly on the end Alvarez has in view.

The book is worth reading and studying. L. E.

The Future Independence and Progress of American Medicine in the Age of Chemistry

Under this title is published the report of a special committee of the American Chemical Society. The volume contains much information of great value to research men in all phases of human progress. Thoughtful students of medicine and pathology will derive a great deal of value from a careful perusal of the report.

It is true that these same students will wonder why the report complains that "the direction of research is still essentially in the hands of medical men"; why the book is written in popular propaganda style; why efforts are being made to distribute one million copies of it and other whys.

The program of medical progress as outlined in the book seems to include "experts" and "specialists" in about every important science except clinical medicine. They do recognize a place for the experimental pathologist in the galaxy of scientific stars that is going to do so much but the physician apparently is an unnecessary element except as an agent to administer the new forthcoming specifics for various diseases.

We are treated to the conclusion that "each human body is now recognized to be a chemical

factory," thus forgetting what others have ignored that there is a mind and a soul that are not accounted for in their formulas and predictions.

It is a pity that such a fine collection of facts in such a worthy cause should be put forth in publicity by a million copies in an attempt to influence an audience of millions of readers most of whom are, of course, unable to understand or appreciate what it is all about. It is also a pity both from the standpoint of science and the good of all that the report increases the lack of confidence in physicians, which seems to be a fashionable custom of so many recent "scientific" reports.

The report is being distributed by "The Chemical Foundation," 81 Fulton Street, New York.

Essays on Surgical Subjects. By Sir Berkeley Moynihan, K. C. M. G., C. B., Leeds, England. Octavo of 253 pages, illustrated. Philadelhpia and London: W. B. Saunders Company, 1921. Cloth, $5 net.

A series of essays reprinted from various journals and collected in one volume. They are, as a whole, not equal to what we have come to expect from Moynihan's brilliant pen. A memorial essay on J. B. Murphy begins with a fine appreciation but soon digresses into an epitome of the whole history of medicine. A series of papers on peptic ulcer express Moynihan's views on treatment. He may, perhaps, have had occasion to change them a little in the three years since he wrote them. The pipings of a rising chorus of discontent with the operation of gastro-enterostomy are making themselves heard—most of them coming, it is true, from the internist's camp—but some of them, too, from the surgeon's. It will be interesting to hear Moynihan express his views ten years from now.

The best paper in the book, "The Ritual of a Surgical Operation," gives an insight into the reasons for his success as a surgeon. It is delightful to find so logical and thoughtful a development of pre-operative technique—a thing which to so many surgeons is a matter of indifferent and slipshod misarrangement. L. E.

New and Decadent Literature—"Why is it necessary to write about the indecencies of life when it is known that the young people of the present day will be the curious readers? The time will come, of course, after a surfeiting of this stuff, when it will cause a moral nausea, and the better class of literature will come again into its own."—The Journal-Lancet, March 1, 1922.

What Next?—"And the same necessity which compelled Jesus to accept His apostles from the ignorant fishermen of Galilee, rather than from among the scribes, pharisees and publicans of His day, now compels the Chiropractic schools to accept those who present themselves for students, and with this material as the warp and woof to weave the fabric of the Chiropractic profession."—(Quoted from a half-page advertisement in the Metropolitan Magazine).

Gas and Oxygen—The consumption of gas and oxygen for purposes of anesthesia is rapidly increasing throughout the country and particularly in the hospitals of California. This increased demand for these very useful but dangerous substances is liable to become an attractive field for ultra commercialists who are more desirous of making money than of producing a thoroughly reliable drug. Once more we wish to caution our members, and hospitals in particular, to be careful as to what and how and at what price they buy their gas and oxygen, and to be particularly careful about unusually attractive commercial propositions in this field.

POTASH AND PERLMUTTER ON "NEW DOCTORS"

(By Montague Glass in the San Francisco Chronicle of Sunday, April 2, 1922)

"Yes, Maruss," Abe Potash said, as he read in the paper of the latest attempt to license massage operators as doctors, "nowadays a lot of fellers expect you to call them doctor when you talk to them, which only a few years ago would have been glad if anyone called them mister even. In fact, Hey, you! Say! or even Psst! was the most respect they ever got from anybody, and today they are doctors yet! An idea!" Potash and Perlmutter say many other interesting and amusing things in the article referred to.

Kind-to-Animals Week—In the kindness-to-animals week let us extol the blessings of vivi-section to animals. By sacrificing a few hogs to a more comfortable death than cholera the whole porcine kind can be free of the agonies of hog cholera. A needle prick and a slight fever in a few cattle saves millions of cattle from anthrax.

Even the moral example, the avoidance of inflicting pain, the true sense of animal values of the vivisectors, has spread their lesson of kindness to animals.

When you send your precious pet to the dog hospital the skilled treatment it gets there is the product of vivisection. So let us make every humane society a center of vivisection propaganda and devote the kindness-to-animals week to inculcating kindness, the humanity, the merciful pain-saving of vivisection.—(Chester Rowell, in San Francisco Bulletin.)

Agitation for Free Choice of Physician in New York and What It Leads To (by Oliver G. Browne, published by The Self-Insurers' Association)—Physicians who are interested in industrial medicine or in the problem of the socialization of medicine or paternalistic government in general will find some most interesting reading in this little pamphlet of three pages. It shows what some laymen think of the medical profession.

The Physician As An Instructor in Health—"Only by utilizing the general practitioner as a health agent can the public receive the health information it needs and desires. When it is realized that disease in its preventive stages rarely comes to the notice of health officers, the role of the doctor assumes great importance. In order to further preventive medicine in Great Britain, the author urges that medical students become instructors in health as well as physicians in disease, that the Council of the British Medical Association inaugurate a constructive disease prevention policy, and that the medical profession assume the responsibility of maintaining the nation's health, not leaving it entirely in the hands of voluntary agencies and public health officials."—Sir Napier Burnett in Nation's Health.

An Unusual and Efficient Method of Furnishing Medical Care to Poor People—The city of Redlands, San Bernardino County, allows its poor people to have the services of any physician in the city whom they choose to call. All the physician has to do about his fee is to make out his bill in accordance with the fee schedule of the State Industrial Accident Commission and the bill is paid by the city treasurer. So far as the information is available this system has worked to the entire satisfaction of the physicians, is extremely satisfactory to poor people, and the cost to the city treasury has not proved to be large. This method might with advantage to all people be copied by other cities.

Obituary

E. M. Fly, M. D., National City, California.

This month we are called upon to chronicle the death of Dr. Edward Monroe Fly for the past twenty-four years one of the most prominent physicians and surgeons of San Diego County. He died after a short illness following an attack of influenza.

Dr. Fly was one of the men who will be missed most by those who knew him best, as his many acts of charity and kindness to his patients were only known to himself and those who were most intimately acquainted with him.

Dr. Fly was born in Easton, Pa., October 13, 1866. Received his early education at Trachs Academy at Easton, Pa., and later graduated from Lafayette College, receiving the degree of A. B. in 1888 and A. M. in 1891. Following this he taught school for several years, then was assistant superintendent of Holmes Sanitarium at Hudson, Wisconsin. Later he studied medicine at the University of Minnesota and Jefferson Medical College, graduating from the latter in June, 1894. He practiced medicine in Plumsteadville, Pa., for three years, when his ambition for a larger field caused him to give up his Plumsteadville practice and seek a new field in the southwest. Arriving in San Diego he decided on National City as being a good opening for his future activities, where he started in with his usual vim and energy, establishing for himself a reputation second to none.

He was prominent in all medical and social activities of the local medical societies, member of the A. M. A., State Medical Society of California, San Diego County Medical Society, American College of Surgeons and the Academy of Medicine. He was an ex-president of his county society and had frequently represented it in the councils of the state organization. He was also a member of the Shriners, Scottish Rite, Knights of Pythias, Odd Fellows, Elks, Woodmen of the World, the University Club of San Diego, and the San Diego Country Club.

Dr. Fly's ability, generosity, integrity, and courtesy were by-words of his many friends. His ability to work and get at the bottom of conditions that baffled others was his delight. Always firm in his beliefs and opinions until they were proven wrong. He was endowed with physical power for an unlimited amount of work, working with his patients all day and studying until the small hours of the morning was his custom. This fact was probably a factor in his early and untimely death.

He will be greatly missed in the community as a citizen, in the medical profession as a leader, and a man that any community could ill afford to lose. E. S. C.

H. BURT ELLIS, M. D.

(Born May 17, 1863. Died April 15, 1922.)

Dr. Ellis was one of the most prominent physicians in California. He located in Los Angeles in 1884. He had served as president of the Southern California Medical Association, the Los Angeles County Medical Association, the California State Medical Society, and was a Fellow of the A. M. A.

DEATHS

Adams, James T. Died in Berkeley, Calif., April 27, 1922. Was a graduate of University of Vermont, 1896. Licensed in California, 1920.

Briggs, A. E. Died April 10, 1922, in Sacramento. Was a graduate of Medical Department, University of Illinois, 1896. Licensed in California, 1898.

Ellis, H. Bert. Died in Los Angeles, April 15, 1922. A past president of the Medical Society of the State of California. Was a graduate of the College of Medicine, University of Southern California, 1888. Licensed here, 1889.

Fiske, Harold A. Died in Los Angeles, April 18, 1922. Was a graduate of the Medical Department, University of Vermont, 1895. Licensed in California, 1901. Was a member of the Medical Society of the State of California.

Mansfield, I. L. R. Died in Oroville, Calif, April 28, 1922. Was a graduate of Philadelphia University of Medicine and Surgery, Pa., 1869. Licensed in California, 1878.

Medros, J. J. Died in Oakland, April 8, 1922. Was a graduate of Cooper Medical College, California, 1894. Licensed in California, 1895. Was a member of the Medical Society of the State of California.

Weeks, Robert Eaton. Died in Los Angeles, April 8, 1922. Was a graduate of Detroit College of Medicine, Michigan, 1904. Licensed in California, 1920. Was a member of the Medical Society of the State of California.

White, Harry O. Died in San Francisco, April 23, 1922. Was a graduate of Harvey Medical College, Chicago, Ill., 1896, and University of Illinois Medical College, 1904. Licensed in California, 1915.

Wilder, C. H. Died in Oakland, Calif., April 9, 1922. Was a graduate of College of Physicians and Surgeons, Illinois, 1895. Licensed in California, 1904.

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.

SOME PRACTICABLE PROBLEMS CONFRONTING THE MEDICAL PROFESSION *

PRESIDENT'S INAUGURAL ADDRESS

By H. G. BRAINERD, M. D., Los Angeles

We have reason to congratulate our profession for what it has accomplished in the matter of protecting the public since the last meeting of this Society, namely: the defeat of the so-called "quack quartet" amendments to our State Constitution. The campaign against these amendments was carried on by the League for Conservation of Public Health in a masterly and successful manner, and we tender to the League our congratulations. But we should bear in mind that this was accomplished by the help of that portion of the general public which believes in the altruism of our profession, believes that our efforts were actuated by our desire to protect the public, and not merely by selfish interests.

If the rising tide of poorly equipped aspirants to practice medicine—those who are trying to acquire the title of "doctor," and the right to treat the sick without the proper educational training—if this tide is to be checked, we as a united profession should do our utmost to influence our patients and acquaintances so that they will vote against any measure which tends to lower the standard of requirements for the admission to the practice of medicine. The work of poorly educated physicians must inevitably increase the length of disability as well as the mortality of the sick. And that our efforts should be made most effective in preventing dangerous legislation this coming session of the Legislature, every doctor in the State should join the League, which so successfully conducted the campaign last year.

A few days ago a patient told me that he had been devoting his time to a physician for nearly a month, during which time he was put through a basal metabolism test, urinalyses, a blood count and a Wassermann test, a test meal and stomach contents analysis, tests to determine the condition of his bile, bismuth meal, and X-ray of stomach and bowels. After which he was presented with a bill for two hundred and fifty dollars, and the opinion that there was nothing the matter with him. In point of fact he was suffering from melancholia from an easily found cause.

Another man of moderate means told me recently that a surgeon performed an operation on him, attended him for two weeks after, and presented him with a bill for seven thousand five hundred dollars. Now it happened that several of this patient's friends had been operated for similar trouble, and some of them were able to leave the hospital sooner than he. And, as they had paid from one hundred to one thousand dollars, he naturally felt that he had been robbed.

Such experiences do not tend to increase the respect for the members of our profession as honorable citizens, or exalt them as learned physicians. It is this sort of thing that helps to foster and perpetuate quackery and charlatanism. Let each one of us remember that every time we are careless in the treatment of our patients, every time we violate the confidence reposed in us, every time we are unjust in our charges for our services, we are not only likely to make enemies for ourselves, but also enemies to the medical profession in general.

It is these, and similar embittering experiences, that are responsible in part, at least, for the establishment of new sects in medicine. The birth and survival of any new sect is concrete proof that something is lacking in the principles or the practice of medicine at that period.

Thus, a century ago, Hahnemann was able to found a new sect because it voiced a protest by the public against the large and nauseous doses prescribed by the old-line physician. A generation ago Doctor Still was able to establish a new sect largely because by his method a physical examination was made, an opinion promptly given, and treatment begun immediately without the bugbear of delayed and expensive laboratory examination and purchase of expensive drugs. And this sect, by reason of less expensive services, prompt diagnosis, and treatment beginning at once, has appealed to a large number of people.

It is an unfortunate fact that the public everywhere exaggerates our shortcomings and minimizes our good deeds. Indeed, it never seems to occur to most persons that every successful step in

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

public health work curtails the income of the physician; and that the thousands upon thousands of free beds in hospitals where free medical services of every kind are given, cut in directly upon the physicians' means of existence. Yet it is to the everlasting credit of our profession, that the very poor everywhere in our land can receive the very best medical treatment available.

At the present time, through the efforts and generosity of the medical profession, the very poor and penniless persons are provided for in case of sickness. But there is another class, and probably the largest and most important class of all, for whom no such provision is made. I refer to persons of moderate means who find it very difficult in case of severe illness to obtain the medical treatment and care that is now available only to the rich and the very poor.

Here is a case in point: An acquaintance of mine recently had typhoid and I tried to find a hospital for him. I applied to five large hospitals and could find but one that would accept him at all, and that at a rate of fifty dollars a week. In addition, the hospital would require two nurses at seven dollars and fifty cents a day each, and the attending physician's charge would be five dollars a visit—a total of one hundred and ninety dollars a week, exclusive of medicine and the cost of personal laundry. As the patient's salary was one hundred dollars a week, this hospital treatment was out of the question. So a less expensive doctor and less expensive nursing were obtained, and the patient was successfully cared for in his apartment.

This single case illustrates a condition that exists in every community today. It is estimated that less than 10 per cent of the people of the United States are able to pay the present fee bill rate of doctors, nurses and hospitals through a long sickness. But there are five times as many who do not wish to be classed as paupers by accepting free medical and hospital services which are now available for the very poor.

This condition is a reflection upon our civilization, but certainly not a reflection upon the medical profession; for most of the medical charity in the world emanates from the regular medical profession, and all of preventive medicine also comes from this source. But, having accomplished so much, I believe it is up to our profession to accomplish still more by devising some means whereby people in moderate circumstances can receive prompt and efficient medical attention at a price within their ability to pay. If our profession does not do this, State medicine, or some other equally distasteful method, is inevitable.

The increase of knowledge in physio-chemistry that has taken place in recent years is, indeed, astounding, and especially along the lines of metabolism and blood conditions. And, also, the advance in the various other means of making diagnoses. Yet it does not follow because of these greatly increased aids of the laboratory that we should subject every patient to the ordeal of having all these things tried out on him. And it is my opinion that the physician should exhaust all his ability and resources at hand before he subjects his patient to the expense and loss of time required by such examinations. For there are many cases in which any observing physician can make a correct diagnosis without this elaborate and expensive laboratory investigation. And resorting to such methods in simple cases often tends to discredit the knowledge and judgment of the physician in the eyes of his patient.

The situation is very different in obscure cases. And, of course, in such cases free use should be made of all the expert opinion and scientific methods available. But the patient should not be sent from one physician to another, or to a succession of laboratories, unless it is absolutely necessary for an accurate diagnosis. And I wish to urge the physician not to neglect his own knowledge, training, and powers of personal observation to the extent of placing dependence upon laboratory diagnosis alone. He should always bear in mind the personal equation and psychology of his patients, which the laboratory does not consider at all. And remember that encouragement, which gives hope, unquestionably hastens the progress of recovery in almost every disease, and that discouragement tends to retard recovery. It is our neglect of this common sense psychology, and its adoption by charlatans, that, in a measure at least, is responsible for the establishment and continuance of the various sects in medicine.

Bear in mind that humanity is governed very largely by emotional rather than by scientific thinking. And if we neglect this great factor in the practice of our profession, the status of our profession will suffer proportionately in the opinion of the public at large.

After writing the above I found the following editorial in the New York Medical Journal:

PHYSICIANS NEEDED

"Columbia University is one of the most richly endowed and the largest of the universities, and its school of medicine has been one of the most progressive in adopting new laboratory courses and enlarging its curriculum. In his annual report as president of the university, Dr. Nicholas Murray Butler presents some important matters in regard to medical education. 'The true aim of the medical school,' says President Butler, 'should be to give instruction in fundamental principles and methods, to bring the students into contact with realities, to train him in habits of observation and inference as to physiological and pathological phenomena, and to give him knowledge of where to look for the additional or specialized information that he may need before his own experience has sufficiently widened and deepened to bring it to him.'"

President Butler realizes that the purpose of the medical school is primarily to train physicians, and not scientific investigators. "It would be a sorry day," says Dr. Butler, "for the public health and for the public satisfaction if the physician of large, practical experience, wide human sympathy and keen insight into human nature, were to yield his place to the expert with the miscroscope and the test tube. The scientific aspects of medicine must not be permitted to override its human aspects."

Dr. Butler has put into words a feeling which

is prevalent throughout a large portion of the medical profession. The true province of the physician is to heal the sick. Under the rapid development of specialism in medicine this function has been lost sight of in some of the larger medical schools, which train scientific investigators instead of physicians. There is need for scientific investigators, but the crying need is for men of broad medical education whose senses and powers of observation, as well as their minds, have been carefully trained; men who depend mainly on their own trained powers of observation and deduction rather than on the differential blood count, the sphygmographic tracing of the electrocardiogram, or the findings of the test tube. All of these aids to diagnosis are of value and should be made use of, but none of them can take the place of the trained and acute observer.

The leaders in medical education have made the mistake of trying to combine the laboratory specialist with the general practitioner, and as a consequence the public has suffered and is suffering from a dearth of doctors.

We were very much pleased to note recently that the Association of Chemists, which had been working during the war for our Government, devising destructive explosives, poisonous gases and other methods for taking human life, is now putting its strength into investigation that will tend to prolong life. Thus another important body of scientific investigators have joined our ranks—have become allied with a profession whose aims have always been conservation of life and health.

Another problem coming before the medical profession with steadily increasing importance is to determine the status of the lay psycho-analyst and the lay psychologist. It is a well-established fact that many cases of mental abnormality, and mental unbalance, are due to definite physical disorders. And it seems hardly proper that persons unable to diagnose physical ailments should be permitted to direct the care of mental cases whose condition may be dependent upon such ailments. It is, indeed, presumptuous for such half-trained persons to attempt the treatment of such cases—a striking example of how really dangerous a little knowledge may be in the field of medicine.

A somewhat similar sentiment may be expressed about another branch of investigation and actual accomplishment of psychology. I refer to the recently developed method of measuring human intelligence. Making due allowance for the over-enthusiastic claims as to the scientific accuracy of such tests, it seems to be fairly well established that it is now possible to measure a certain department of an individual's intellect and determine with fair accuracy just what degree of intelligence he possesses as compared with other normal individuals. But such measurements apply to one department of the human intellect only, and do not offer a means of measuring such vital things as judgment, courage, initiative, morality, honesty, or many forms of mental aberrations and abnormalities. And yet, certain persons trained in this laboratory method of making mental tests are arrogating to themselves the ability to thus judge human nature in all its complicated phases. But in the last analysis the correct judgment of individual human nature is still best determined by those whose training is largely obtained in the great natural laboratory of human contact and observation. At present, as in the past, no class of persons receive as complete training in this great "laboratory," or are as good practical psychologists, as the physicians.

The present status of the medical expert in giving evidence in the court is most unsatisfactory. A very excellent bill in regard to such evidence was introduced and passed by a recent legislature, but failed to receive the governor's signature. This bill applied not solely to physicians, it is true, but perhaps more largely than to any other professional class. A bill somewhat similar to the one just referred to will be introduced in the next Legislature, and will meet its principal opposition from the legal fraternity, notwithstanding the fact that most judges, and the better class of the legal profession, apparently favor some change in the present system.

According to the methods now in vogue, the expert is employed by one of the litigants, and is, therefore, likely to have a partisan bias. Furthermore, the hypothetical question propounded to this expert usually minimizes those facts which are inimical to the party that employed him, while facts of the opposite character are introduced and stressed as much as possible. And thus it follows that the expert of necessity becomes something of a partisan because he does not have all the facts presented to him in their true perspective.

The bill to be presented this winter will make the calling of an expert by the court a necessity, and will provide to have all the facts presented to him before forming an opinion. We trust that the bill will receive the hearty support of the medical profession.

It has been shown very forcibly that the majority of the criminals who are repeaters are mental defectives, a still larger percentage of persons in the almshouses who are cared for by the public are also mentally defective, and likewise a very large percentage of prostitutes. Moreover, the fact stands unchallenged that the greatest source of mental defect is defective parentage.

The place for the early detection of these mental defects is the public school, and it seems to me that the State should take steps to search out all defective individuals during these formative years of childhood. And if such defectives become delinquents, the State should make provision for their future care, and should take means to prevent the propagation of their kind.

And meanwhile let us go forward unitedly raising our morale and our scientific attainment to the highest possible standard, so that our actual accomplishment will convince the public that the members of the regular medical profession place the best interest of their patients and of the community above their own selfish interests.

Four hundred years before the Christian era Hippocrates and his school caused everyone who was to start practice as a physician to take the most solemn oath, as follows:

"I swear by Apollo, the physician, and by Escu-

lapius, and I call Hygeia and Panacea and all the gods and goddesses to witness that to the best of my power and judgment I will keep this oath, to-wit:

"I will adopt that system of regimen which, according to my ability and judgment, I consider for the benefit of my patients, and will protect them from everything noxious and injurious. I will give no deadly medicine to anyone, even if asked, nor will I give any such counsel, and similarly I will not give to a woman the means of procuring an abortion. With purity and with holiness I will pass my life and practice my art. Into whatever houses I enter I will go into them for the benefit of the sick, keeping myself aloof from every voluntary act of injustice and corruption and lust. Whatever in the course of my professional practice, or outside of it, I see or hear which ought not to be spread abroad, I will not divulge, as reckoning that all such should be kept secret."

It was the custom in this country and in Europe to administer this oath to applicants for graduation in medicine, and I would urge that there be a return to that custom in our medical schools, and that this oath in bold type should be where the eyes of the practitioner would frequently rest upon it.

Shall we, who have had the benefit of twenty centuries of Christian teaching, have less high ideals than those of the heathen Greek?

"THE LIE DETECTOR"

Recently in reporting a medical congress for the public press, a reporter "discovered the ophthalmoscope." He told in fine headlines how, with this new instrument, the physician could look into the eye and could see many things, including the brain. The article inferred that this instrument was a recent discovery and physicians were urged to adopt it as one of their important instruments of precision. Of course, every physician knows that the principle of the ophthalmoscope has been in use for hundreds of years and that the instrument was made practical seventy-one years ago.

California is seeing much of the same sort of "publicity" regarding the sphygmomanometer. Here also the principle involved has been used by physicians almost since the discovery of the circulation of the blood. It has been a recognized instrument of precision in diagnosis for about a quarter of a century.

There also is nothing new in using the principle to detect feigning or suppressed and masked emotions. It is, of course, well known that disturbances of the emotions, from whatever cause, produce fluctuations in blood pressure, respiratory control and many other functions. That the sphygmomanometer or any modification of it will distinguish between types of emotion or physical being accurately enough to be accepted as evidence in murder trials certainly remains to be proved. Many physicians who use the sphygmomanometer frequently in their daily work will pronounce the "lie detector" a liar.

MEDICAL EDUCATION OF PRESENT AND NEAR FUTURE*

By RAY LYMAN WILBUR, M. D., Stanford University, California.

The present generation has witnessed a complete transformation of medical education in America. The apprentice method was followed by the lecture system with demonstrations in anatomy, pathology and various clinical subjects. This in turn has been more recently supplanted by the laboratory, the small bedside clinic and various forms of hospital work, including in some institutions a required interne year. A study of much of our present medical practice shows that it is based largely upon pathology rather than physiology. This has been a natural outgowth of the development in the use of the microscope, the study of autopsy evidence and the growth of the science of bacteriology. In brief, as a result of our methods of training we can say that the art of medicine has been largely based upon the use of drugs and that the art of surgery has been likewise based upon pathology removable by the knife. Because of the importance laid upon anatomy and pathology in the training of medical men and the general desire for perfection or one hundred per cent result, which is characteristic of the American, we have gone through a stage in which there has been an insistence upon the part of the surgeon and gynecologist that his patient should be brought up to the standard of a so-called normal topographical anatomy. By surgical means there has been a very definite attempt to see that all organs were located in definite positions rather than to make a careful study of the physiology of the organs, which is, of course, of outstanding importance. Anyone who will look over the text books of gynecology of a decade ago cannot help but be impressed with the pedantic insistence of the gynecologists as to the so-called normal position of the uterus. Fortunately in this sphere normality of function is being recognized as the final test.

Particularly since the enlightening and epoch-making work of Louis Pasteur there has been an enormous growth of medical knowledge. Science in every field has made rapid strides forward and many of the advances made have been brought by the medical profession into the field of diagnosis or of therapeusis. While there has been an increase in the time required for the course leading up to the degree of Doctor of Medicine and while preliminary subjects, such as physics, chemistry, biology and languages, have been insisted upon, there has been a constant stuffing of the medical curriculum with all of the new methods and facts so that we can say that at the present time the curriculum and courses of the medical school have been *inclusive* in so far as possible.

The time has now come for the curriculum to be studied from the standpoint of *selection* and

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

exclusion rather than from that of inclusion. In one way or another we must reduce the actual amount of time consumed in obtaining a medical education and we must reduce the content of the medical course by the most rigid selection of that which is fit to survive and that which is necessary in order to turn out a safe practitioner. The efforts of the last decade in medical education have been directed towards fewer and better medical schools, better fundamental work and the gathering together of the necessary funds for the large expense involved with the bringing of the laboratory and the bedside clinic into the medical school. There has been by one process or another, largely because of increasing requirements on the part of the individual medical school, a limitation of medical students which has almost reached the danger line of providing too few skilled and trained men for the service of the public. When we realize that it takes at least twenty-five years, practically half of a man's life, to prepare himself for medicine and that there is a vast amount of energy and expense involved in each individual case, it becomes of vital importance for us to see that there is no waste either of money or of energy in obtaining the result.

One of the most troublesome tendencies of present medical education has been associated with the rapid development of the various specialties. There has been a marked refinement of technique and a great increase in the technical appliances in all of these specialties. They have been more and more crowded into the medical curriculum until they have seriously interfered with the necessary development of the basic subjects of medicine, surgery, obstetrics and gynecology in the clinical years. In fact the result has been that many students have done considerable work along special lines before they have received the degree of Doctor of Medicine.

We must return to the basic idea that the granting of the degree of Doctor of Medicine means that a student is capable of handling the ordinary problems of general practice. This is certainly necessary before he can be safely trusted to advance in any special field. In the ordinary small community we find the general merchandise store. One can obtain there the essentials of human life in ordinary existence. If one wants any special appliance or something unusual it takes time to obtain delivery and one must either send or go to a larger field. This illustrates general practice and also the requirements for every medical man. In our larger centers we have the department store, where there is a marked extension of everything represented in a general merchandise store with experts in charge of each department. Medicine, likewise, is handled in this way where specialists in various lines are available. In the general merchandise store the proprietor knows everything that he has on hand and how to guide his customer to get promptly the essential things that he needs. In the general department store much is left to the customer himself. Without guidance he may overpurchase in a single department when his real needs lie in another. It is inevitable that there shall be these two forms of organization. One of the ways to protect the person who deals largely with specialists is to have the specialist understand thoroughly the essentials of general medical practice.

The bringing of the university spirit into medicine, which has accompanied the development of the laboratory, has not been without its defects. That very accuracy which is required for scientific work of a university grade has been inclined to make us somewhat too pedantic and to seek for impossible accuracy. It has also been inclined to make the medical profession poor psychologists. We have been so intent upon the actual chemical and other processes involved in the care of our patients that we have neglected the mental reactions of the individual concerned. It has been hard for us to realize that the man with syphilis needs healing of the mind as well as the giving of arsenical preparations to kill the spirochaetae invading his body. We have also been neglectful of the fact that the sick man out of a job needs light work and mental repose as well as diet and nitroglycerine for his high blood pressure. The cold scientific turn of thought that must necessarily go with the laboratory method needs the leavening effect of intimate association of all medical teachers with all classes of ailing humanity.

The experiment of bringing the so-called full-time academic teacher into medicine has been successful where the full-time teacher has had the privileges of the ordinary academic professor of mapping out his program of life for himself. We cannot expect a satisfactory development of medical teachers if we overemphasize the protection of the laboratory and the clinic ward to such an extent that a man does not have to develop the proper psychological and mental attitude required for the art of medicine. One reason why we have been losing our grip to some extent upon our patients is that we have lost the personal touch and the feeling of responsibility for the individual's life in all its phases.

It seems quite clear that it is impossible for us to grant more time for the preparation of medical students, so that we must modify to a marked degree our present curriculum and see that there is a definite selection of subjects and courses. With these points in mind, what shall be the program for the development of medical students in the near future?

In the first place, it is evident that the basic work must be the same. No man can hope to enter the medical field who is not thoroughly familiar with physics, chemistry and biology. He must also have that general knowledge that any good citizen who is to be a leader requires. He must likewise have familiarity with at least one foreign language, so that he may come in contact with the medical spirit and medical literature of another

nation. Beyond this we must recognize that the profession of medicine is definitely committed to:

1. Preventive medicine,
2. Relief of the sick, and that all of its work is based primarily on:
1. Etiology,
2. Perverted or pathological physiology,
3. Diagnosis,
4. All known forms of relief.

We must recognize that preventive medicine as fostered by the medical profession has completely changed the practice of medicine.

In the early days in Philadelphia the medical practitioners had to deal with jail fever or typhus, smallpox, cholera and yellow fever. Modern sanitary practice and engineering have changed our relationship to many diseases common a few years ago. Typhoid is an excellent example. I saw an autopsy on a case of typhoid fever in Munich which attracted the attention of the whole profession of Bavaria because such a thing was a rarity, and yet some of the greatest studies upon typhoid fever were made in Munich because it was a constant focus of infection, as were many of the cities of Europe. A rearrangement of the water supply was responsible largely for the change.

The type of practice of a decade ago permitted much symptomatic treatment. Diseases were allowed to run their course. The doctor was, in a way, the protector and nurse and comforter of the patient. The marked advances made in preventive medicine make it inevitable that the medical student of today and tomorrow must study the normal more than the abnormal and that he must be familiar with the incipient stages of all disease processes and recognize the first perversions from normal physiology and the first signs of abnormal pathology. The old easy practice of medicine has gone never to return. Great skill in the recognition of the early stages of disease means pre-eminence in medicine in the future. It is unfortunate that these periods of the beginning of disease are most susceptible to quackery and to deceit. We are all familiar with the phrase "threatened with pneumonia" or "threatened with disease." It is also inevitable that the very fact that we are able to relieve patients in the early stages of their diseases will in a way interfere with their interpretation of our success.

The man who has an early operation for appendicitis often has such an easy time following his operation and during his convalescence that he sometimes wonders whether the operation was necessary. There is still great respect for the doctor who lets the patient go so far that he is only able to save him by the most energetic and persistent attention. This need not interfere with sound medicine and an increase in the respect on the part of the public for medicine. There is a gradually rising level of intelligence among our people, and more and more of them are getting some biological understanding of life.

In particular, we must prepare the medical student for practice among the children who are now growing up in our schools, where they are obtaining considerable knowledge of nutrition, physical training, the general facts of biology and many of the facts of preventive medicine. The child who is being weighed and measured at the school and told what it is desirable for him to eat in order that he may grow will have very different ideas from those of us who have grown up in the present generation, for our childhood was full of health precepts, the development of so-called health foods, and we were certainly influenced by the period of quack advertisement represented by Lydia E. Pinkham and the lost manhood group.

Our physician in the near future must have new conceptions of disease and its effects upon collective human living. He must be a social leader and must recognize that the one great possession of the human race is its germ plasm. This germ plasm needs guardianship from disease and other malign influences, for if it deteriorates a family or a race soon dies out. The profession of medicine has been most advanced in its willingness to accept new facts and to use them at once for the relief of the sick. At the same time, the traditions of the profession have been very powerful and there has been a constant tendency to look backward as well as to look well to the front. We cannot fail to recognize that we have been over-enthusiastic many times in the reception we have given to apparent discoveries. Fortunately, these waves of interest soon die out and leave, for the most part, a firm residue of fact and truth behind. We are forunate now in seeing the unsavory mess of Freudianism replaced by endocrinology. Just what the next thing will be, it is hard to say, but it will soon be upon us. Like all human beings, we keep reaching out for the final panacea in the hope that we can give general relief to everyone. Our whole history tells us that we must build our medical structure slowly brick by brick.

With the complexity of modern life many new forces have been added to those of the doctor in handling the sick. We must readjust our curriculum so that the young physician can be trained for the leadership of his lieutenants:

1. The trained nurse.
2. The physiotherapist.
3. The dietitian.
4. The radiologist.
5. The laboratory worker.
6. The social service worker.

The control of lieutenants means that some administrative training is requisite for the physician.

It seems to me that in making the new adjustments in the medical course we should proceed along the following lines:

1. Squeeze out the non-essentials.
2. Bring in hygiene and preventive medicine as working assets.
3. Make the graduate a general practitioner, not an expert in any particular field.
4. Direct a tangible, earnest study of all recog-

nized methods of treatment, not seek for panaceas, but give relief from suffering.

5. Have actual practical work in the clinics and laboratories, which must be brought closely together.
6. Develop mental clinics and the study of psychology.

The doctor of medicine in the future must be the master in the field of the prevention of and the relief from the ills that beset mankind. He must be versed in:

1. The anatomy, physiology, chemistry and pathology of the human body.
2. He must be thoroughly familiar with the life histories of and the effects produced by the parasites that live in us and cause most of our ills.
3. He must know individual and group psychology.
4. He must know something of our social organization and economic life.
5. He must be an expert diagnostician of the early stages of disease and a personal therapeutist selecting and using all known and tried methods of relief.

The medical man who is unwilling to obtain this necessary fundamental training and to see that a specific service is rendered to the patient by him or by some one of his appointed lieutenants should take up some form of medical work which does not require contact with the patient. Each one of the lieutenants of a doctor has taken away from him a certain amount of his contact with the patient. He can at least secure intimate association with the patient through a most careful physical examination. This, with the history, should establish that intimate feeling between the patient and the doctor that is requisite for confidence and success.

We must frankly recognize the fact that, as a profession, we are thought of too much in terms of drugs and the knife and that we have become somewhat isolated from the sick patient because of the machinery that we have built up. The success of the illy trained individual who deals with the sick comes largely from his direct contact with the patient and the mental effect produced therefrom. Each one of the various cults has some element of fact as its basis, often of a purely psychological nature.

We should study every field of therapeusis with our scientific methods and extract from each field the things that are serviceable and worth while. The medical profession should set the battlefields of the future in the matter of therapeusis rather than have them set for them, as is the case today. The only cure for the quack who now adds so much to the sum of human woe is to train our medical students to do their work so well and to get the medical profession to unite so thoroughly in their administration of prevention and relief that every member of our human society gets his share. We cannot afford to take care of only the very poor who appeal to our sympathies and of the well-to-do who can pay us well for our services. We must organize the medical services of our community so that all may be offered the advantages of modern medical science. We must remember that the sick man is a social unit. He needs help for himself physically and mentally and for his family. We must establish the proper relationship of the sick individual to the community and be the connecting link in this relationship. Finances is only a small portion, although the most obvious one, of this relationship. We have the knowledge, we have the organization, we have the traditions of prevention and treatment. The problem is in our hands. I think that we can rely upon the medical students now in our medical schools, if they are given the proper guidance. Their quality is excellent. I doubt if there is any better aggregation of brains in the country. The training required for the degree of Doctor of Medicine in a first-class medical school today exceeds that for the degree of Doctor of Philosophy. These men and women are capable of meeting the problems along the lines suggested, in the near future, if we will lay the basis now.

The physician who cares for the individual and foresees and prevents the disasters that involve his body and mind and the engineer who lays the basis for safe and economic life will be the leaders in the years ahead.

PROVISIONS OF WORKMEN'S COMPENSATION ACT OF CALIFORNIA RELATIVE TO FURNISHING OF MEDICAL TREATMENT IN COMPENSATION CASES. *

By W. H. PILLSBURY
Attorney for Industrial Accident Commission

Primarily, the rights and duties of a physician in treating any case are fixed by his contract with the party ordering his services. The person requesting his services expressly or impliedly agrees to pay him for them, and he agrees to furnish his skill and care. If the agreement between the parties specifies a fixed amount as payment, both sides are bound by the agreement; if not, the physician is entitled to collect the reasonable value of his services, to be fixed by the court with reference to standard prices for similar services.

The Workmen's Compensation Act does not change this fundamental contractual basis. The physician still looks to the person asking him to treat the case for payment, either in an agreed amount or for the reasonable value of his services. All that the Compensation Act does is to give an additional recourse under certain circumstances, as indicated below.

The Compensation Act requires the employer, or if the employer be insured, his insurance company, to *furnish* necessary medical treatment. Correlative with this duty is the right of the employer

* Read before San Francisco Medical Society, January 17, 1922.

or insurance company to select the physicians to treat the case. In furnishing treatment such physician is usually hired by the insurance company and is to be paid by the insurance company upon ordinary principles of contract, as indicated above. If, however, the employer or insurance company neglect or refuse to promptly furnish medical treatment, the injured employe is not obliged to go without treatment, but can immediately call in a physician of his own choice, for whose services the employer or insurance company must eventually pay. In such case the physician has his ordinary contractual right against the person calling him into the case, and also has a right under the Workmen's Compensation Act to hold the insurance company for the reasonable value of his services. In such case the question of reasonable value is to be fixed by the Industrial Accident Commission instead of by the courts. In fixing the reasonable value the commission is obliged, if the litigants are technically inclined, to listen to testimony of other physicians, etc., as to standard charges for such treatment. As a matter of practical expediency, however, the parties almost always agree to leave the determination of the fee to the medical director of the Industrial Accident Commission, and his decision is almost never appealed from.

In addition to furnishing an attending physician, hospital treatment, medical supplies, crutches, etc., the insurance company is also obliged under the Compensation Act in any serious case to furnish the services of a consulting physician to be named and paid by the insurance company. If the employe is dissatisfied with the attending physician, he is entitled, without proving any good cause for dissatisfaction, to ask the employer once for a change of physicians. In that case the employer must nominate at least three additional practicing physicians competent to treat the particular case, from whom the employe is entitled to choose.

The employe is entitled to only the one change of physicians. If he is dissatisfied with the list of three he may, however, require the Industrial Accident Commission to approve the competency for the case of these physicians. This does not mean that the commission personally examines each physician and expresses its view of their qualifications; it only means that the commission, if invoked, will consider whether the physicians on this list hold themselves out to be specialists in the line necessary to treat the particular case. For instance, the commission would not approve the nomination of an eye specialist for orthopedic work, or vice versa. Here again, as a matter of practice, the certification is always left by mutual consent to the medical director of the commission, upon whose advice the commission acts.

In all cases the injured employe, if further dissatisfied, can call in his own physician without loss of compensation payments, the only bad result in such case being that the employe must pay his own medical expenses thereafter. The same is true if he desires additional consulting or other physicians.

THE PROBLEMS OF INDUSTRIAL ACCIDENT INSURANCE*

By JAMES H. PARKINSON, M. D., Sacramento

The first part of this address constitutes the report of the Committee on Industrial Accident Insurance and is published on page 244 of this issue of the Journal.

There are certain general facts or principles involved in the question of Industrial Medicine that the profession must keep constantly before it.

Compensation insurance with which we are now struggling is only one phase of a movement which may be generally described as socialized or centralized State medicine. Its logical conclusion is the centralization of all medical activities in the State, and the elimination of a profession functioning as individual or independent physicians. Special phases of the question are the so-called welfare work and social work. All these various activities function by and through the medical profession without which they cannot be conducted. They have been enormously stimulated by artificial conditions in time of war and have been fostered and encouraged by a most generous, charitable and patriotic profession. Directly or indirectly these agencies are fed and nursed by the taxpayer and so have helped the State expenditures to the appalling figure of $60,000,000 for the year 1920, the last figures available, or an increase of 220 per cent from the figures of 1910, when these activities first commenced.

As citizens, members of the profession must carefully consider the trend of the times, for the signs on every hand point to a general revolt against the conditions and a recognition for the need of reform lest the revenue raising capacity of the State be exhausted.

As significant of this trend of opinion, the following brief extract is in point:

Mr. John A. Edgerton, president of the National Association of Manufacturers, speaking at their annual convention in New York on May 9, 1922, says:

> The chief economic problem of the day is there are too many middlemen in the industrial fabric, with too many persons engaged in distributing the products turned out by the farmer and the manufacturer.
>
> When we add to this excess of distributors, the countless number of whose chief activities are to reform, regulate, inspect, denounce, tax, plunder, and otherwise live upon those who are trying to produce something, it will not be difficult to discover the principal factor in the continuing high cost of living.

In connection with the question before us today, I would strongly commend to your attention the article of Dr. Goodale appearing in the May number of the State Journal. By permission of the Secretary I will now read a letter from the Fund, which also bears upon the subject:

Dear Dr. Musgrave:

It would seem incompatible with my public duty to pass without comment the article in your May issue by Dr. George W. Goodale under the head, "A Statement of the Problems of Industrial Medicine in California." It is also possible that your

* Presented at the Fifty-first Annual Meeting of the Medical Society of the State of California, at Yosemite National Park, May 15, 1922.

readers would be interested in a statement from me as repesenting the official viewpoint of the State Compensation Insurance Fund.

The motive behind Dr. Goodale's article can only be guessed, but his picture of the situation is so palpably inconsistent with his relation to the compensation system and his operations in the past, and his own conception of the law creating the State Compensation Insurance Fund is so out of harmony with the expressed intent of the statute, that his statements of fact should not be allowed to go unchallenged.

The article referred to is obviously intended to arouse a feeling on the part of physicians that they are about to face a dangerous economic situation brought about by compctition between this fund and other insurance carriers. Contrary to that picture, the most recent development of moment was the adoption by the Medical Society of the State of California, after careful consideration by a special committee of a fee schedule for industrial cases intended to represent a 25 per cent increase in remuneration to physicians and surgeons. This increased schedule was then formally approved by the Industrial Accident Commission. I have it, on no less authority than a member of Dr. Goodale's staff and from other surgeons specializing in industrial service, that the previous fees were considered by them to be ample for those doing industrial work in volume and that those men doing the bulk of the active work permitted others less interested to bring about the increase.

If there is any tendency to grind physicians between the millstones of competition, that tendency has been encouraged by those practicing industrial surgery who have, through desire for a volume of work, entered into agreements with insurance companies to accept fees less than those specified in the schedule or to do the work on a basis of a percentage of premiums which brings about the same result. Being one of those engaging in such practices (as recently admitted by one of his associates), it ill behooves Dr. Goodale to intimate that this fund and insurance companies are the ones upon whom the medical fraternity should place the blame. It is a well-known fact that the State Compensation Insurance Fund has held itself above participation in such practices and has endeavored to avoid business dealings with those medical men engaging in them, but it seems pertinent to predict that failure to adopt effective means to prevent such a thing will force the larger insurance carriers to give service through salaried surgeons as a matter of self-preservation in the competitive insurance field.

The author of the article to which we are taking exception has seen fit to refer at some length to the State Compensation Insurance Fund in a way which can only be considered as a thinly veiled criticism of its operation and management. He states: "The original intent of the law was not that the State Fund should be a competitor of the companies in the sense of a business competitor . . ." and proceeds to determine for his readers the real intent of the law. It is deserving of passing mention that his conclusions are not borne out by the law itself and are not concurred in by those charged with the responsibility of interpreting the statutory intent while under oath of office and official bond. The law states specifically that the fund is to be "fairly competitive," that it is to "ultimately become neither more nor less than self-supporting." The law says nothing whatever about its establishment as a regulatory institution, though it is to be admitted that it could not well exercise such a function without soliciting patronage and becoming an important factor in the competitive field. Dr. Goodale plainly states that the management of the fund has fallen into "the common fault of bureaucracy . . ." We must take emphatic issue with that statement and, if needs be, support our claim to a freedom from any such tendency by overwhelming evidence from satisfied patrons, industrial claimants and those medical men who have had sufficient dealings with the fund to know its methods.

I will not attempt to point out all of the misstatements contained in the article, but as examples will mention the following:

It is stated that the law prohibited the State Fund from paying brokerage fees. This is not correct. Payment or non-payment of brokerage was left to the judgment of the management.

It is further stated in referring to the Experience Rating Plan that: "This, if carried out correctly, would do away with the advantage of the State Fund, . . ." That statement is untrue, as the Experience Rating Plan is used by the fund as well as by the companies and is intended to establish a credit for one risk and a debit for another without affecting the general rate level. It could have no bearing upon the fund's ability to pay dividends to policy holders because those dividends are paid largely from savings in administration expense. Here again the doctor is wrong when he states: "Administrative expenses are practically stationary and afford little opportunity for saving." As a matter of fact, the administrative expenses of the corporate companies vary from 30 per cent to 50 per cent, while the administrative expense of the State Fund has averaged about 13 per cent of premiums.

The author of the article mentioned refers to "Rebating by the State Fund as a business propaganda, . . ." That is a rather bold statement, as there is a statute which makes "rebating" a serious offense, and there is a vast difference between "rebating" and paying dividends from profits actually earned. The fund does not engage in "rebating" either in fact or as "propaganda."

It has long been known that certain doctors have engaged in the practice of entering into contracts for medical service at less than fee schedule rates, and the names of many of those doctors are likewise known. Perhaps the setting up of a "wolf cry" may have a tendency to divert attention to other sources as representing a greater menace to members of your Society, but I think we can safely rely upon the common sense of your members to see that the real danger lies in the activities of those doctors who will not co-operate in maintaining a reasonable schedule of fees for industrial surgery.

It is obvious that some insurance companies will purchase medical service as cheaply as possible, and there is absolutely no way to prevent that practice except through control of your own members. Both the Industrial Accident Commission and the management of this fund have co-operated fully in attempts to maintain the schedule of fees and that high character of service thereunder which would bring about the best results to those persons in whose interests the compensation law was enacted. It is a well-known fact that the same cannot be said of some of the members of your Society who have attempted to commercialize practice under the compensation system and who, it seems to me, are on dangerous ground when they use the word "exploitation."

Cordially yours,
(Signed) C. W. FELLOWS,
Manager.

The Fund, organized for the purposes which are enumerated in the Act creating it, has accumulated a very large sum of money which, I

understand, has long since passed the million mark. I venture to predict that the next step in State medicine will be the establishment of State hospitals at selected points, and the creation of a salaried staff to do State compensation work.

In this connection I would call your attention to the significant fact mentioned in our report of last year that, at the previous session of the Legislature, a bill was introduced prohibiting any private or commercial company from writing compensation insurance in California.

We should, however, first clean house. The appropriations now standing in the name of the profession are well over the million mark and unwarranted by our needs or necessities.

What are the remedies? The education and cultivation of public opinion and the enactment of the necessary legislation. A law that will place all State activities more directly within the law and under the jurisdiction of the courts seems a first necessity. A provision for an independent medical tribunal is scarcely of less importance. You have initiated the organization of the necessary machinery; it only remains for you to perfect and use it.

A Poor Foundation—The chiropractors of California are not laying a good foundation for their demand for a new law by openly defying the present law.

The State Board of Examiners announces an examination, at which the chiropractors and other drugless healers can obtain certificates under the present law by showing proficiency in those fundamentals of knowledge without which no practice of the healing art, whether by chiropractic or any other method, is safe to the public.

They will not be examined either in medicine or in chiropractic, but on those sciences in which there is no pretense of sectarian difference. There are no sects of chemistry, physiology, anatomy, bacteriology, and the rest. There are no conflicting dogmas or theories involved. One simply knows them or does not know them. Any chiropractor who knows them can get a certificate to practice. He is not required to know medicine, if he does not propose to practice it, and it is taken for granted that he knows chiropractic enough, provided he knows the other things, without which no one can safely use chiropractic or any other method.

This is the law. Every scientifically educated man regards it as a good law. However, if the chiropractors can convince the majority of the people that the scientifically trained minority are mistaken, it is their right to change the law. It is not their right to defy the law while it is the law.

This is what they are doing. They are practicing without licenses, against the law. When they are convinced they refuse to pay fines and go instead to jail to pose as martyrs, on the pretext that the law which forbids them to practice without license also gives them no opportunity to get the license. Then when, under the law, the opportunity is offered, the Chiropractors' Campaign Committee of California issues a public statement calling on its practitioners to refuse to take the examination and to ignore the law. Which, let it be repeated, is a very poor foundation for asking the people to change the law.—Chester Rowell, San Francisco Bulletin, June 5, 1922.

SUCCESSFUL REMOVAL OF AN EXTRA-MEDULLARY CORD TUMOR IN THE LOWER DORSAL REGION, CAUSING SEVERE COMPRESSION SYMPTOMS—RECOVERY.

By WALTER F. SCHALLER, M. D., and ALANSON WEEKS, M. D., San Francisco

SUMMARY OF CASE.

Onset with severe dorsal root pain, followed by motor loss in left lower extremity and evidence of both cord and root compression below the ninth dorsal cord segment. Progressive paraplegia by involvement of right lower extremity. Predominant flexor "shortening" paralysis. Bilateral pathological pyramidal tract signs and heightened tendon reflexes in lower extremities. Positive Beevor sign. Superficial sensation affected below the tenth dorsal root distribution for pain and temperature. Deep sensation affected particularly for vibration sense. Reflex movements of defense present. Absence of sphincter involvement. Colonic crises. Compression syndrome in cerebrospinal fluid. At operation complete removal of an intradural glioma at the eleventh dorsal cord segment. Convalescent period complicated by anemia, toxic polyneuritis, decubitus. Ultimate complete recovery.

MEDICAL PART.

(By Walter F. Schaller, M. D.)

The patient,* aged 45, was first seen by me on June 23, 1919, at the request of Dr. Alanson Weeks, who at this date had been called in charge and who suspected a cord lesion. Previously well, a man of exceptional physical and mental vigor, the patient's first symptom was pain in the left lower abdomen, superficial and not deep, but severe enough to seriously bother him and cause him to seek medical advice. This was about December 20, 1918. A searching medical examination by a number of consultants, aided by Roentgenographic examination of the abdomen, of the spine, chest, gastro-intestinal tract, and the teeth, revealed nothing definitely abnormal. An apparently bound down sigmoid had at one time suggested the advisability of an exploratory laparotomy, which, however, was not performed. A lumbar puncture was done, the fluid showing no increase in cells or protein content. The Wassermann reaction was negative in the fluid as well as in the blood.

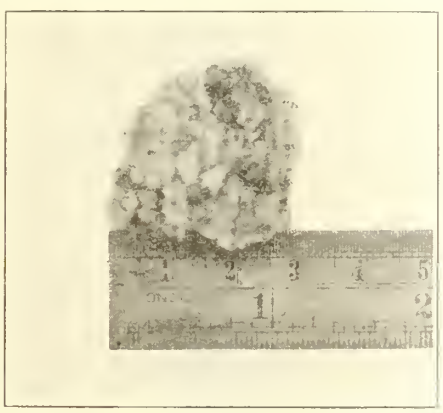
Under symptomatic treatment, hydro-therapy and climatic change, the patient did not improve and opiates were necessary at times to alleviate pain. At the time of my first examination pain was still the most prominent symptom, although considerable motor weakness had developed in the left lower extremity. The pain was more or less constant, of a toothachy character, sometimes lancinating and always worse at night. It was located principally on the left side at the level of the umbilicus, but was also present on the

* Charles M. Fickert, then District Attorney of San Francisco, with whose permission this record is published.

right side below the costal margin, and would often radiate as a distinctly girdle pain to the back. Ordinary exercise, such as walking, had at times caused the pain to disappear. Relief was obtained by sitting in a certain chair at home. In fact, the patient could not rest lying in an ordinary bed and would spend a considerable portion of the night either sitting or standing at the foot of his bed, back bent, and arms grasping the foot of the bed for support. Arising from a sitting or reclining position was particularly painful and the patient would change his posture very carefully, slowly and laboriously.

Shortly before examination additional Roentgenograms of the spine were taken and interpreted as negative. At this period Dr. Ray Lyman Wilbur, who saw the patient, suspected a cord lesion because of an extensor toe reflex.

Examination.—Intellectually the patient was clear, self-contained, not emotional and made the appearance of a man who was under great physical discomfort and pain. There was an apparent loss in weight. An inspection of the musculature of the buttocks and of the upper posterior thighs showed some atrophy in these



Extramedullary Cord Tumor (Glioma) at D_{11}—3x1¼ cm.

localities. Measurement at the top of the left thigh showed a difference of 4 cm. less as compared with the right. In the lower part of the left thigh (12 cm. above top of patella) there was a difference of 1 cm. The spine was held quite rigid, although there was no definite muscular spasm on either side; a moderate amount of both flexion and extension was possible in both lumbar and dorsal regions. The patient claimed great weakness in the left lower extremity; for instance, he could not place the left heel to the opposite knee, whereas this maneuver could be done with the right heel, but at the expense of considerable effort and pain. He could stand unsupported, but swayed to the point of falling with his eyes closed. A considerable edema was noted about the feet and ankles, which was supposed to be due to the long continued dependent position of these members. The blood pressure was 150 systolic, 90 diastolic. Reflexes: The patellar jerks were quite lively but equal; the ankle jerks were moderately lively. The upper tendon reflexes were apparently equal. There was no patellar or ankle clonus. The abdominal reflexes were doubtfully present, but both cremasteric reflexes were definitely present. The Babinski reflex appeared to be positive on both sides, more typically so on the right side, as the response on the left was brusque and jerky, simulating a voluntary motion. The Gordon and Oppenheim tests were negative. Sensibility: Touch was felt fairly well in the lower extremities, but pain and temperature sensations were altered below the segmental lovel of D_{10} on both sides. Deep sensibility, tested by the vibration fork and also by notion of position, was markedly affected in the lower extremities, the vibrations of the fork being scarcely perceived over the malleoli. The handgrips were forceful. The left lower extremity was paretic, as above described, but the muscle tonus in this member did not seem to be noticeably altered. There was some fibrillation present in the lower extremities, perhaps due to exposure (unclad in a room only moderately warm). The pupils reacted to light, the right promptly, the left perhaps less so; the left pupil may have been a trifle larger than the right. The cranial nerves were otherwise apparently negative. There were no speech defects and no facial paresis. Hearing and sight were not complained of. The nurse's chart showed nothing of importance concerning pulse, respiration or temperature.

The impression following this first examination was a paraplegia, and a traumatic radiculitis in the dorsal region due to compression of the cord and corresponding spinal roots.

Progress of the Case.—As the patient was more comfortable in the sitting position and often spent the greater part of the night in this posture, an orthopedic bed was arranged so that the legs were flexed on the thighs and the thighs flexed on the trunk. The edema was considerably lessened by this procedure. It was necessary to relieve pain by analgesics, which were given freely and in combination. On coughing, pain was complained of. Tenderness was experienced by percussion over the seventh dorsal spine. The patient stated that from the onset of his pain he had difficulty in expelling flatus per rectum. Constipation was a distressing symptom. On July 25 there were two enormous evacuations of formed fecal matter and these were followed by several other large evacuations on the following morning; in all, patient had perhaps eight or ten evacuations within a period of twenty-four hours, the nurse stating that over two large chamberfuls of formed fecal matter were passed, representing a weight of perhaps eight or ten pounds. A state of exhaustion ensued, with a temperature of 103 F. and a pulse of 106. The next day, however, the patient had a normal pulse and temperature and felt generally better, with less pain. The history was obtained that he had such an experience about two months before, accompanied by fever and increased pulse rate. These attacks were interpreted as an overflow from a distended and paretic bowel. Throughout the illness there had been no involvement of the bladder function or of the bladder sphincter.

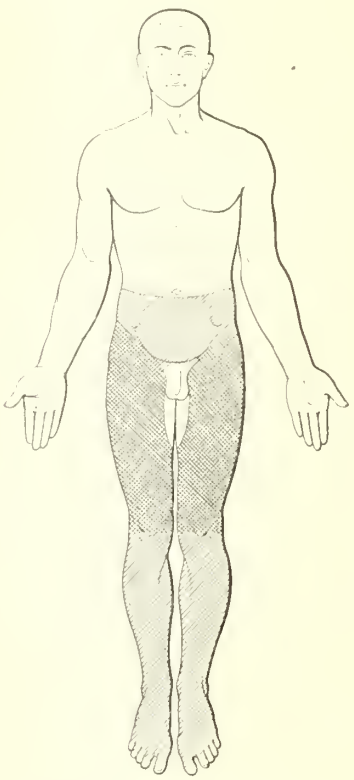
On January 30, 1919, a consultation was held between Drs. Alanson Weeks, Martin Fisher and Walter F. Schaller. Dr. Fisher made a personal examination and believed that the condition was due to either one of two causes in order of their probability: Firstly, compression of the cord; secondly, metastatic infection from a focus in tonsils or teeth, or some other focus. Following this consultation a tonsillectomy was done by Dr. E. D. Shortlidge. Mercury inunctions were then started for therapeutic and diagnostic purposes. After a course of these had been given without any benefit, and the motor weakness became greater, they were discontinued. Re-examination of Roentgenograms revealed no other abnormality than a decided scoliosis of the dorsal spine. No anemia was present on repeated blood tests. The patient was frequently re-examined as to the condition of both sensory and motor systems and the state of his reflexes.

Objective Sensation.—Light touch with cotton fiber was practically intact. Temperature and pain were definitely affected; pain relatively more so than temperature. These disturbed sensations were noticed below D_{10}, but were more pronounced below D_{12}, where heat and cold were at times confused, at times not felt as temperature, and pin-prick was identified as a point but often not felt as pain. As between D_{10} and D_{12} sensation was relatively less disturbed in the legs. A reference to the charts will show conserved areas of riding-breeches design, representing the lowest sacral root innervation.

Reflexes.—When sensation was examined involuntary flexor responses in the nature of defense reactions in the lower extremities were present when stimuli (most noticeable with pain) were applied to the inner parts of the legs and thighs, but also when applied to the outer sides of the legs and outer sides of the feet. The tendon reflexes remained very active, thus typifying a spastic paraplegia, although in one of the last examinations before operation the left ankle jerk was not elicited with certainty. Ankle clonus finally developed, but not patellar clonus. The abdominal reflexes which were at first present changed in that the upper ones were finally doubtfully present. The Babinski extensor toe response remained bilaterally constantly positive. The Gordon and Oppenheim reflexes became questionably positive in the right lower extremity, but not in the left.

Motor System.—The paraplegia gradually increased up to the time of operation; weakness had been greater always in the left lower extremity, and became also very marked in the right, so that finally the patient could not stand even with support. The atrophy in the glutei and posterior thigh muscles increased. A distinct physiological grouping in the relative involvement of muscle groups was observed as follows: In the left lower extremity, those muscles which shortened the extremity—viz., extensors of the toes, dorsal flexors of the ankle, flexors of the leg on the thigh and flexors of the thigh on the pelvis—were very weak, as compared with their antagonists or muscles which lengthened the extremity. Finally, however, as the paralysis increased a paresis was noticed in the extensors of the left leg on the thigh. In the right lower extremity this "shortening paralysis" was also noted and began at the hip and knee joints and only later included those muscles which dorsally flex the right ankle. The progression of the paralysis, therefore, was predominantly flexor in both extremities and progressed from the proximal to the distal portions of the extremities. The extensor muscles were only later involved.

Motor segmental weakness was searched for after the suggestion of Holmes and was found in the upper recti. A positive Beevor's sign was present; in the sitting position an attempt to contract the abdominal muscles revealed a paresis below the navel manifested by a flaccidity of the muscles, but the recti above the navel contracted and the navel ascended. Further, palpation of the intercostal spaces on expiration revealed a decided difference in the tonus of the intercostal muscles of the ninth and tenth spaces, as compared with the intercostal muscles above; the fingers could be deeply pressed in between the ribs in these localities, whereas higher the firm resistance of the normal muscles could be felt. A subsequent examination revealed hypotonic muscles in the eighth and ninth spaces.

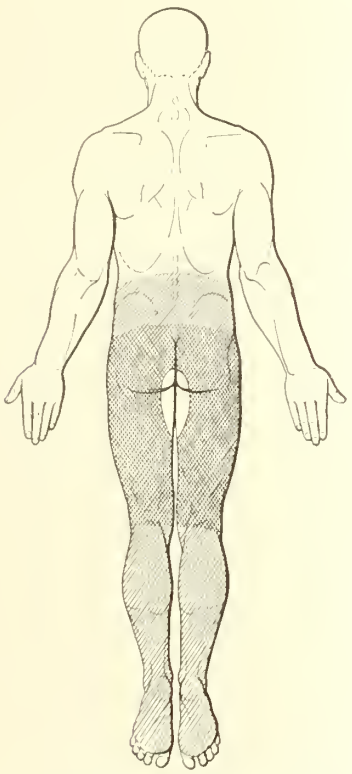


Crossed areas represent disturbed sensation for pain and for temperature. Light touch conserved over the same areas. The uncrossed areas represent conserved sensation.

On August 2 a lumbar puncture was performed and clear cerebrospinal fluid obtained. The pressure was not increased. The laboratory reports

follow: Total cells (red and white) 29, leucocytes 1 per cmm. Nonne and Noguchi tests for globulin strongly positive. Wasserman reaction, cholesterinized beef heart antigen, negative in all amounts.

It will thus be seen that the cerebrospinal fluid showed a typical compression syndrome and that syphillis could be definitely eliminated. A diagnosis was made of an extramedullary tumor situated on the posterior and left aspects of the cord between the ninth and the eleventh dorsal segments. The surgeon was advised to remove the sixth and seventh vertebral spines, which procedure should uncover the tumor.



Crossed areas represent disturbed sensation for pain and for temperature. Light touch conserved over the same areas. The uncrossed areas represent conserved sensation.

SURGICAL PART

(By Alanson Weeks, M. D.)

Operation.—On August 4, 1919, a laminectomy was done by Dr. Alanson Weeks, assisted by Dr. Edmund Butler. Present at the operation: Drs. Schaller and Lennon, the latter having independently examined the patient previously and made a diagnosis of cord tumor.

The seventh dorsal spine was removed, then the sixth, and the laminae removed. As the dura was approached a thickened yellowish tissue was found extradurally, which was thought to compress the cord, and the fifth spine and lamina were removed. This tissue, however, seemed fibrous and was later identified as the ligamentum subflava. Abundant hemorrhage complicated the operation, causing considerable delays. The eighth spine was removed, the bleeding arrested, and the dura opened. At the extreme lower level of the dural opening—i. e., about the eleventh dorsal cord segment and opposite to the eighth dorsal spine—a tumor was seen, causing a considerable depression in the cord on the left lateral surface. This was completely exposed by removal of another spine—the ninth—and the tumor, which lay encapsulated between the dura and the cord, was completely removed. The wound was closed in its several layers, and the patient was removed from the table in excellent condition.

The tumor was of soft consistency, measuring 3 x1½ cm., was quite friable and broke into two portions when removed. The consistency and appearance of the tumor suggested a cellular growth. It was histologically examined by Dr. William Ophuls, whose report follows:

Sections show a fairly cellular tumor consisting of bundles of short fusiform cells between which there are many delicate fibrils, which do not stain with the Van Gieson method. In places there are many large blood capillaries. Few mitoses. Some fibrous tissue about the blood vessels. Glioma.

POST-OPERATIVE COURSE

In the first three days following the operation the patient was quite restless, at times nauseated, but was, generally speaking, in fairly good physical condition. His pain was controlled by morphine as was necessary. The pulse, although high at times (122), was of good quality. The temperature averaged about 100 degrees F. At midnight on August 6 there was a rise in temperature to 101° F. and the chart noted that patient was at times mildly delirious. August 9: "Wriggled toes of left foot." He had two chills on this date with temperature following of 103° F. and 103° F. It was then noticed that pressure areas over sacrum and the right hip, which showed circulatory disturbances and abrasions before the operation, had broken down. The usual changes in postures were insufficient to control the extension of these processes, so on August 14 the patient was placed in the prone position following the development of a pressure area on the left hip. The wounds were irrigated and dressed daily. The patient was weak, depressed, irritable and complained of pain in both hips, and particularly in the left hip. A blood count on August 14 revealed 2,600,000 red cells, with 58 per cent hemoglobin. On August 17 a blood transfusion of 500 cc. was done. The red count then gradually but slowly increased until, on February 25, 1920, the count was 4,000,000 red cells, with 67 per cent hemoglobin.

Because of the sepsis following the small pressure sore present at the time of the operation and the big abscess which followed in the gluteal region and over the sacrum, the patient was in a more or less critical condition—very toxic, with a septic temperature as high as 103 degrees F., perspiring at times profusely, losing weight, with poor appetite; irritable and sleepless because of pain and discomfort. Involuntary cramp-like

contractions in the flexors of the lower extremities was a distressing complication. These contractions persisted until the middle of January, 1920, interfering with rest and sleep, as they would awaken patient at night. The temperature finally fell on September 27, to remain down with only an occasional remission afterwards. Notwithstanding the decubital wounds, which still discharged for months, the patient was evidently on a fair road to recovery. He was kept in the prone position continuously until his temperature became normal, and part of the time for weeks and months afterwards. Toward the latter part of September another complication arose, which was the cause of much additional suffering to the patient and much perplexity to his attending physicians. Pain in the left shoulder was bitterly complained of, extending down the left upper extremity and progressing to the right shoulder and down this extremity. Opiates were necessary for rest and sleep. Soon muscular atrophy was noticed in the dorsal interossei of the hands and later in the triceps. Both hand-grips were weak. However, the upper tendon reflexes were conserved. It was an open question whether this complication was caused by another compressive lesion in the cervical region similar to that found in the dorsal region, or whether it was due to a postural traumatic neuritis from the patient being in the prone position so long, or whether a polyneuritis had developed from pyogenic infection. The ultimate course and eventually complete recovery made this last condition seem most probable.

Clinical Notes of Convalescent Period.—On November 3, 1919, the operative wound in the back had completely healed and decubitus in the left hip had practically healed, but over the sacrum there was a granulating area and a small fistula exuding some pus; over the right hip there was still a gaping wound, clean, about three or four inches in length, which ran down between muscle planes to the great trochanter. These two wounds persisted until the latter part of February, 1920. The neuritis of the upper extremities gradually subsided, so that in January the pain had disappeared, although weakness of the upper extremities still remained.

The first definite improvement in the lower extremities was noted early in November, when the muscular force at the ankles and knees was decidedly increased, and disturbed sensation for pain and for temperature was decreased. At this period, however, notion of the position of the great toes was still faulty and the vibration sense was also still profoundly affected over the bony prominences of the left ankle. The Babinski reflex, although still present bilaterally, was less pronounced, especially on the left side. This reflex finally disappeared in March, 1920.

Toward the last of November, 1919, the patient was able to stand with support; two months later he was able to take several steps with but slight support; in March, 1920, he was able to take a few steps unaided, and commenced to be about on crutches. There still remained, however, some strophy of the glutei, especially on the right side, and these muscles were distinctly hypo-active to both the faradic and galvanic currents.

Involuntary tonic contractions, which were especially marked after operation, were among the last symptoms to disappear, and persisted as a tendency even after the patient could walk quite well. These contractions were most marked in the right lower extremity and were finally only present in the early morning. Also at this time (March) superficial sensation had returned except for occasional confusion of temperature sensation below the knee. Postural sensation had returned. Osseous sensibility was not yet felt normally over the malleoli.

In July, 1920, the patient again reported. He had made a complete recovery, walking without any abnormality of gait. He had suffered no inconvenience from a recent walk of five miles; no pain, weakness or instability remained.

COMMENT

From the neurological standpoint the complete recovery after the severe paralytic compression of the cord was remarkable. The exquisite predominant flexor paralysis suggested either a close anatomical grouping of physiologically related motor tracts in the cord or a greater susceptibility of these tracts to pressure. The motor segmental weakness was an important guide in establishing the level of the lesion. The sensitiveness of the seventh dorsal spine seemed to be of diagnostic importance. The conserved vesical and rectal functions were exceptional in the presence of the marked paraplegia. The colonic crises were perhaps explained by a splanchnic paralysis due to an abrupt change in intra-abdominal pressure.

The sparing of touch sensation, with the involvement of both pain and temperature sensation, has been described by Dejerine as characteristic of cord compression. The shifting character and variations in disturbed superficial sensation has been noted previously in compressive lesions. The marked disturbance of the vibration sense would tend to confirm Mingazzini's statement that the fibers which transmit vibration run in the vicinity of the pyramidal tract and that their disturbed function is concomitant with a disturbed pyramidal tract function. Relief of pain and distress on coughing by the flexor position suggested root tension. The evident polyneuritis which this patient suffered as a complication was one of the relatively rare cases following infection. Noteworthy was the long continued painful involuntary reflexes in the lower extremities.

From the surgical standpoint the removal of five spinous processes and laminae had not apparently interfered with the free motion or usefulness of the spinal column. Immediately placing patients in the prone position following spinal operations for paralysis is recommended because of the danger of causation or extension of decubitus.

CLINICIANS PAST, PRESENT AND FUTURE

By HERBERT C. MOFFITT, M. D., San Francisco

The word clinic meant originally a bed or a bed-ridden person. A clinician is one who studies disease at the bedside or, broadly, "one who makes a practical study of disease in the persons of those afflicted by it." That clinician is now used most often as synonymous with internist is an admonition to the straying feet of surgeons and specialists.

We speak complacently of the limitations of the ancient physician, but think on the other hand of some of his advantages: no piles of ever-multiplying journals to load his desk, little bothersome technique to acquire, few cumbersome machines to transport to the bedside; no solicitous drug house to dictate his treatment; opportunity to use each one of his special senses, time to exercise his *common* sense; a hazy idea of the internal mechanism of the body, what it looked like and how it worked, but at least the chance to see a body left fairly whole unless lopped by war, and to study the reaction of this body at different stages of its development to disease of all kinds. As far back as two to three thousand years before Hippocrates, observation and experience had advanced medicine fairly far along certain lines in Mesopotamia, India and Egypt. Physicians had acquired libraries of written lore, been divided into varied cults, seen the rise of varied specialties. Even group medicine was foreshadowed in the Babylonian custom of placing patients in the market place so that all who passed might question, examine and give an opinion about the disease.

No one can dispute that Hippocrates must rank as one of the world's great clinicians. Pliny would have him the first clinician—"for there arose Hippocrates who received and set on foot again the ancient practice of Aesculapius . . . and being borne in Coos a renowned and wealthie island altogether devote and consecrated to Aesculapius he made an extract of all receits, which were found written in the temple of the said God . . . and after that the said temple was burned, hee professed the course of Physicke which is called Clinice (that is Chamber—Physicke, so called because hee visited his patients lying sicke in bed)." About the clinic at Coos and about other Esculapian temples as well gathered students who were systematically instructed and to whom before entering practice the Hippocratic oath was administered. Histories of patients were taken, physical examinations carefully made, methods of treatment —especially hydrotherapy — demonstrated. The physician and the priest worked side by side in the temple, and faith entered largely as a factor into cure. Harmony was more perfect, results of treatment at least as good as in the Emanuel movement of our own days. The compilations of Hippocrates and his followers still will repay the medical student, and commentaries of the Grecian and Roman periods show problems in medical teaching and practice much like our own. The unity of the profession was early split by dogmatists, methodists, empirics, eclectics, pneumatists and other cults. Of making many books there was even then no end. As Osler wrote: "The little by-play between Socrates and Euthydemus suggests an advanced condition of medical literature; 'of course, you who have so many books are going in for being a doctor,' says Socrates, and then he adds, 'there are so many books on medicine, you know.'" There was not wanting protest even then against increasing complexity of medicine; Thessalus of Tralles, who grew rich in the reign of Nero, maintained medicine could be taught in six months. It is true he then proceeded to publish a treatise in eight volumes. Pliny inveighed against eternal changes in teaching and practice: "but withall they must marvel much, and thinke it a great indignitie, that no science and profession in the world hath had lesse soliditie in it and been more unconstant, yea, and how it daily changeth still."

With Galen, who gave us what may be termed the first voluminous system of Medicine, the period of the ancients came to a close. His teaching exercised profound influence upon the minds of men throughout the long period from the fall of Rome to the discovery of America. Probably, as Boerhaave held, it did more harm than good; until finally blasted by that explosive charlatan Paracelsus, soon after the dawn of the sixteenth century. But medicine was not wholly benighted during the medieval period. We all know something of Aetius, Alexander of Tralles and Paul of Egina. Not only was Aetius a surgeon and internist, but he removed tonsils and specialized in diseases of the eyes and teeth as well. Alexander of Tralles found it necessary even early in the seventh century to protest against unnecessary operations. He thought prophylaxis of disease the most important study for a doctor. We all know the high standing of Jewish and Arabian physicians in the Middle Ages, and still may read with interest writings of Rhazes and Avicenna. Through slow development in the early Christian era the school of Salerno reached its greatest dignity in the tenth, eleventh and twelfth centuries. Its students, from all over Europe, spent three years in premedical work in philosophy, four years in medicine and one year with a practitioner before entering their profession. Later schools at Bologna, Padua, Pisa, quickened with the spirit of the Italian renaissance, profoundly influenced discovery and teaching in medicine everywhere.

From the time of Vesalius, Servetus, Harvey and Morgagni to that of Pasteur, Lister, Koch and Virchow, clinicians were molded in a fashion that we can all appreciate. Sydenham and Boerhaave, Auenbrugger, Corvisart, Laennec, Louis, Heberden, Withering, Parry, Hunter, Jenner, Graves, Stokes, Corrigan, Bright, Addison, Gull, Schönlein, Wünderlich Skoda, Dupuytren, Trousseau, were nearly all of them practitioners with a bent for teaching and investigation. Their preliminary education was simple and had much in common, particularly a thorough drill in the clas-

sics. They were frequently teachers of the natural or medical sciences. Their interest in anatomy, physiology and pathology was none the less real because directed chiefly to the elucidation of problems of disease in man. If they went far as surgeons or specialists they still kept in plain view the broad medical field. Even in more modern times when wealth of discovery and increased specialization began to separate from the busy general practitioners a group of medical men in charge of university or medical school clinics or of consultation practice in their communities, these men entered upon this varied work with many views in common. They had under their feet the firm foundation of general pathology and general medicine. They had all seen disease in varied aspects, in various stages, under varied circumstances.

With the tremendous development of the natural sciences, the astounding transformations in medicine following the discoveries of Pasteur, Lister, Virchow and Koch, the phenomenal rise of surgery and surgical specialties, came also rapid changes in social conditions, a rush of men to the cities, growing impatience with lessons of the past, a profound faith in anything that was fin de siècle and new. Even against these forces clinicians for a time were able to stem their way and to keep fairly intact the broad field of medicine. They entered clinical medicine usually after a basic training in general pathology. They again had the advantage of a common starting point, of a knowledge of disease as a whole and in its varied aspects. If they became specialists in a particular field it was at a later date and with the teachings of general medicine well in mind. Their hospital material was not sacrificed to the demands of varied specialties and their students, early anchored to the clinic, had more opportunity to study disease, though less chance to develop technical methods. This training gave us clinicians like Traube, Charcot, Fournier, Gowers, Jonathan Hutchinson, Weir Mitchell, Fitz and Osler. Their ability to teach and to investigate was enhanced, not weakened, by their experience and success as practitioners.

Gradually in the past twenty years medical schools, hospitals, teachers and the profession have been remolded under pressure of new discoveries, new methods, new appliances, new specialties. They have been unduly influenced, moreover, by the craze of recent years for universal standardization, organization, regulation. Premature enthusiasm has at times been reflected in premature legislation until a very intricate specialized system of education has been elaborated not only in medical schools, but in universities and hospitals as well. At the same time intricate and far-reaching problems have been forced upon the practitioner.

Enthusiasm for results achieved by technical skill, by special concentration, by discoveries in laboratories, has lessened appreciation of the less showy work of the general practitioner and medical clinician. As Mackenzie says: "The faith and trust in laboratory methods renders the physician incapable of appreciating the value of methods peculiar to clinical medicine. In an attempt to be up to date physicians use the methods of these auxiliary branches, so that clinical medicine toils laboriously in their rear, and to a great extent becomes subservient to them." There are enthusiasts today who would dictate the very ways men must travel to reach success in practice or teaching, who would block all roads to advancement of the clinician in school or hospital, except those that lead through laboratories. Theirs is the impatience (to paraphrase Barker) with knowledge not expressed in equation or graph. It is high time to do away with such intolerance and fetishism. The clinician of today and tomorrow is being jammed into a complicated educational machine and forced, often against his will, into narrow specialism. For this, as Mackenzie writes: "To a great extent the physician is himself to blame. He has allowed himself to be dazzled by the inventions of his colleagues, and has accepted their methods and ideas, not recognizing the limited scope of all such methods, while his own vastly more important field has been neglected."

Results of surgical work and other special treatment in many instances have been overestimated by profession and public alike, and the need of technical appliances and highly trained specialists in private and hospital practice has been unduly emphasized. Medical discoveries have not only at times been overvalued, but they have been prematurely announced and embodied in legislation that later proved unwise. We have often promised too much too quickly, and now zealous specialists in medical education, State boards of examiners, and State boards of health, Federal authority and well meaning but often misguided public opinion are forcing medicine to deliver goods not yet produced. As Abraham Jacobi said: "The public . . . is unable to follow or correctly rate the results of unobtrusive and unornamental brain work." Yet it is the fashion for guileless individuals within the profession to discuss with the laymen all sorts of intimate problems and to publish for their consumption volumes of half-baked science and unfermented theory. Years ago that wise physician, Dr. J. M. DaCosta, in speaking of "excessive publication of half-knowledge, of doubtful fact and of loose inquiry," added the comforting reflection, "who knows that it is not, after all, a physiological function giving full play to brain centers in very rare use—centers situated in what Oliver Wendell Holmes has called the idiotic area of the brain."

How can we best preserve all that was good in the older methods of teaching and practice without sacrificing any essentials of the new? How will the clinician regain in the confusion his former broad field and solid foundation, how reassemble his scrambled material, how get back his patients scattered among a score of specialties, how restore his dominant prestige in profession and clientele? In my opinion the solution of many vexing problems lies in the simplification and unification of medicine. If our machinery—educational, professional, social and bureaucratic—has become too cumbersome and complicated, scrap and reassemble it. Early in their career give our students some common foundation, some general background so that

they will have more associations in common. Bring them a year or two earlier to the university with better knowledge of history and language (including their own) than they have now. In the university by all means let them study science, but let them browse in the field of humanities as well. If possible bring them to a medical school with close intercommunication of scientific and clinical departments. Do away with the fetish that they must laboriously acquire the technique of all laboratories before entering the clinical field. Put them at work in a hospital with few divisions, preferably only medicine, surgery and obstetrics, and with an outpatient an integral part of each clinic. Let them have teachers who see private patients of all ages and kinds. Try to offset forces in hospital organization and in legislation tending to scatter material of general medical and surgical clinics. Cut and simplify the medical curriculum by avoidance of needless repetition and by elimination of special teaching. By all means utilize specialists in teaching, but let them emphasize more plainly the foundation of each specialty upon general medicine. Wider range through all departments of the school and hospital may safely be permitted the student in the fifth year, and opportunities freely granted in later years for development in any field—not excluding general practice.

In a few years men should be sent out, perhaps with a smaller mass of technical knowledge, but with wider vision, better judgment, wiser, more tolerant, better able to observe, to think and to decide. They would be better clinicians, better clinical specialists. Meanwhile let the profession be distrustful of too much regulation from within or without. Let us clear medicine of false glamor and bunk, get a juster appreciation of results, and get more common sense into practice and into the public mind. We have made tremendous advances in twenty years, but we have still a lot to learn. Recent experiences with pneumonia, influenza and encephalitis should make us all duly humble and appreciative of our therapeutic limitations. Despite the tremendous amount of laboratory work of recent years we know little more about nephritis than taught us by Bright. We have spent a lot of money on sanitariums for tuberculosis without adequate return. We have overrated in the professional and public mind the results obtained by arsphenamin and discredited wholly without reason the use of mercury and iodid in the treatment of syphilis. We are constantly rediscovering facts well known to older clinicians—witness the recent enthusiasm for yeast, codliver oil and lemon juice. The clouds are lifting a little, however. We are becoming a bit doubtful that end results of surgery are always fine. There is fortunately a growing feeling that clinical judgment is an essential in medical education as well as training in fundamental sciences and laboratory technique. The intolerance of the purely laboratory man or the early specialist for all other branches of medicine will probably not last long. More knowledge of the valuable teaching of the past may lead to saner progress in the future.

In practice we can probably do without an awful lot of machinery, and an awful lot of social workers, and special nurses and physchoanalysists. We need not send nearly the number of patients into hospitals that we now do. We need not subject nearly so many to operations. We need not overemphasize the value of intravenous and vaccine therapy that requires too frequent office visits. We may safely lay stress upon the value of time in diagnosis and treatment and not be rushed off our feet by enthusiasts in and outside the profession to try methods only because they are new and for the sake of doing something. Let us be sure that ultra scientific medicine is truly *wise* medicine before putting it into practice, and let us be a little wary of milleniums and panaceas. Let us get better acquainted with our patients before passing them over to groups of supermen to be analyzed and organized and specialized and finally integrated and perhaps treated. Let us realize that they, the patients, have some rights and often little money—that they have parts not all described in the anatomies which are often strangely moved by forces outside the ductless glands. Let us keep our feet firmly planted on the good firm old ground of general medicine, and it will not matter so much if our heads are sometimes in the clouds.

Even clinicians are not without the usual failings and foolishness of ordinary men, and will at times do fool things. We doctors, all, however, have certain redeeming qualities: traditions, ideals and a fair desire for work. We should pray for a somewhat wider, saner outlook into the rather dubious future. We need have no petty jealousies in the profession. We are in the end all workers in one field and should be proud of individual achievement in however remote a part of it. The words of Plato should still ring true—"There is *one* Science of Medicine which is concerned with the inspection of health equally in all times, present, past and future."

Fad of Replacing the Uterus—The multitude of pessaries, intra-uterine and vaginal, which marked the displacement era of sixty years ago, have almost all disappeared into museums as antiquities or curiosities, and now the ring is almost the only survivor. In the surgical area through which we are now passing, the modern counterpart of the pessary inventor is the deviser of suspensory and sling operations on the uterus. The woman with a uterus that will not sit up straight can have a tuck taken in its round ligaments, or have it held up by the ligaments being stitched to the abdominal wall, or delicately supported by the ligaments being clasped behind its back, and so on ad infinitum. The attitude of mind of these suspenders of the uterus is precisely that of the mid-Victorian pessary-monger; their methods only have changed with the times, and these operations are quite as much overdone as the pessaries were, but do less harm. There is not the bad mental effect of continuous pessary wearing with the recurrent need for changing, and there is the advantage that the patient has two or three weeks in bed with a change and convalescence, together with the strong suggestion that now the errant womb has been made right, she also ought to be right.—J. S. Fairbairn, Brit. M. J., 1:587 (April) 1922.

FUNDAMENTAL FACTORS IN THE ETIOLOGY AND TREATMENT OF CHRONIC INTESTINAL DISEASES *

By HUGH F. FREIDELL, M. D., Santa Barbara, Calif.

This paper is a discussion of those very prevalent deranged gastro-intestinal conditions which are characterized by either hyper or hypo-peristalsis and which are functional in nature.

In the hyper-peristaltic type is found the hypersensitive and irritated intestine and colon with spasms, diarrhea, spastic colitis and mucous colitis. This results in undernourishment and varying degrees of intestinal distress. In the hypo-peristaltic type is found the slow sluggish intestine and colon with resultant stasis, fermentation or putrefaction, constipation and distension.

Patients of these classes appear before us every day and they have been very aptly dubbed "The Chronic Intestinal Invalids."

The most common causative factors in both the hypo and hyper-peristaltic types are the widespread use of intestinal irritants, such as laxatives, cathartics, purgatives, and such irritating enemas as "glycerine," "soap-suds," "one-two-three and two-four-six," "turpentine," and others so much used in post-operative cases, as well as the large water enemas or flushings constituting the so-called "Internal bath."

The use of these harmful irritants is seemingly indicated at times, due to the markedly unbalanced diet upon which the average individual exists. Ample literature in medical journals, textbooks, public press and commercial advertisements make it easy for the physician to prescribe cathartics or enemas for the relief of intestinal conditions without carefully considering etiology and without carefully considering the end result of advising the patient to start, or to continue if already started, the cathartic or enema habit.

It is common to note in the histories of patients with intestinal disease and distress of various kinds, that the trouble dates from the time they were operated on for this or that condition. Upon careful questioning, it is brought out that although they had never used cathartics or enemas before the operation, such was instituted at the hospital during their convalescence and was continued after their discharge. Some surgeons are prone to leave the handling of the intestinal function to the care of the nurse in charge. The peddling of pills and routine giving of irritating enemas take place in some of the best hospitals. The patient leaves the hospital on such a regime and, of course, follows it out at home.

Treatment of these diseases should be based upon a working understanding of the physiology of the gastro-intestinal tract and should consist in efforts to restore the normal state to the definitely abnormal intestine. Material enters the small intestine in a liquid to a semi-liquid state. It is pushed through the small intestine by the longitudinal peristaltic movements. As it progresses it is divided, and thoroughly mixed with the intestinal juices and brought into intimate contact with the absorptive surfaces by the segmenting and circular contractions of the muscle walls. Most of the nourishment is absorbed from the small intestine. The material that enters the large intestine is composed chiefly of water, indigestible debris, bacteria, salts, a few starches and organic acids. It is brought into intimate contact with the absorptive surfaces of the colon, in a similar manner as in the small intestine, except that anti-peristalsis in the cæcum and ascending colon inhibits the movement of the material. Due to the absorption of water, salts and occasional starches, as the material progresses through the colon it becomes less fluid and in the sigmoid it is quite pasty. The material remains in the rectum until enough of the remaining fluid is absorbed to give the stool a consistency hard enough to stimulate the rectal nerves for a desire for defecation.

The intestinal movements are produced mechanically by the bulk of material and chemically by reflex action through the sympathetic, motor and vagatonic nervous system.

Within certain limits there is a normal time for the passage of material through the gastro-intestinal tract. The radiologists, using a barium suspension, consider there is no retention in the stomach if the meal is out in six hours, in the small intestine in from twelve to sixteen hours, and in the large in from thirty-six to forty-eight hours after ingestion. Naturally a foreign, rather non-absorbable, material, such as the barium solution is not the ideal means of testing the gastro-intestinal function. Food should be used. This is easily done by feeding a charcoal tablet with the meal and timing the appearance of the black stool. This has been repeatedly done in normal individuals and the stool appears in from thirty-six to forty-eight hours.

This normal mechanism is maintained by a properly balanced diet. A properly balanced diet is one that nourishes, as evidenced by the maintaining of the normal body weight, and one that contains enough of the irritating material to produce a normal stool every day, without intestinal distress and without artificial aid.

This normal metchanism is of the utmost importance and should be constantly in mind when attempting to treat these intestinal conditions. One of the most important factors is the time it should take for the material to pass through the gastro-intestinal tract. Food should not be rushed through the stomach before it has entered into solution with the gastric juices. The material should not rush through the small intestine before sufficient time has elapsed for the nourishment to be absorbed and if it is rushed through the large colon, the body will be depleted, more or less, of necessary fluid, a common finding in diarrheas of even short duration. Any factors that disturb this mechanism, the most common of which are artificial stimulants, cathartics and enemas, will cause these absorption times to be disarranged and if kept up day after day, will result in chronic intestinal disease.

In the treatment of the hyper-peristaltic type

* Read before the Sixty-fifth regular annual meeting of the Southern California Medical Society.

cathartics and large enemas should never be used, except in the very aged and then only after unsuccessful attempts without artificial aid.

A preliminary rest of the small intestine and colon should be instituted. This is obtained by physical, mental and metabolic rest of the patient combined with proper soothing medication. Daily evacuations of the bowels should be assured in order to establish the normal habit and prevent fecal impaction in the rectum.

Mental rest is important because many of these patients are intensely neurotic. It is best obtained by taking the patient into your confidence, explaining to him fully and simply the normal mechanism of the intestine, pointing out to him his errors in his own management and explaining just how you expect to get the intestinal function back to normal. It will take a good deal of assurance to obtain and to retain the patient's confidence in your ability, as the line of treatment is so opposite to the general point of view. It is difficult at times to make the patient appreciate that he will have bowel movements without cathartics, especially when he has used cathartics and enemas for years. However, if the patient is intelligent he will usually give you a fair trial and when he begins to have stools without distress and artificial aid, his gratefulness is very pleasing. He must have a good working knowledge of the form of treatment so that he can intelligently continue it after his discharge from the hospital.

Physical and mental rest, obtained by keeping the patient in bed for a week or ten days, is necessary because exercise stimulates the intestinal peristalsis.

An easily assimilable diet and one non-irritating to the intestines containing a minimum amount of indigestible debris and irritating material, is essential. Heat should be applied to the abdomen during the major portion of the day by the judicious use of an electric pad. This soothes the hypersensitive nerve endings and the inflamed mucous membranes of the intestine and quiets the intestinal peristalsis. Soothing medication in the form of bismuth and chalk powders is useful.

Daily evacuations are assured by enemas of two or three ounces of warm olive or cotton-seed oil, given at night and retained until morning if possible, without distress. This lubricates the rectum, softens fecal material and does not enter the colon itself. These enemas are soothing, they form the morning habit or cause it to continue if already formed, and they prevent fecal impaction. These enemas are stopped as soon as the diet is complete enough to cause stools to appear normally. Normal stools should be the rule before patients are discharged from the hospital.

During the treatment everything possible is done to rest the intestine and colon, so that they will have every opportunity to regain their normal tone and reaction to stimuli. During this period patients will have stools with the aid of oil enemas. These stools come from the material ingested before treatment is instituted and after that from the intestinal secretions, bacteria and bismuth and chalk powders. The bismuth and chalk powders usually contain 10 grains each of bismuth subnitrate, calcium phosphate, and calcium carbonate and should be dissolved in water and taken five times a day, after feedings. The powders are soothing to the inflamed mucous membranes, form a coating over the sensitive nerve endings, rendering them less susceptible to stimuli and provide for a non-irritating bulk. The oil retention will prevent fecal impaction in the rectum.

After three or four days of non-irritating regime, the diet is gradually increased, from the non-irritating to the irritating food, adding food of the least irritating nature first.

The diet in the beginning consists of cereal gruels made of farina, barley, oatmeal flour and rice, strained, made thin with water and served hot five times a day. On the second day boiled milk is usually substituted for two or three of the gruels; on the third day soft cooked eggs with toasted crackers may be added; then gradually day by day, add food such as cereals, with cream and sugar as desired; tender bits of well-cooked meat and game, custards, toast, cocoa, tea or weak coffee. Up to this stage the food is practically all absorbed as nourishment and is non-irritating in nature. This phase of the treatment is usually completed in a week or ten days. Then if distress is absent and stools are formed, the more irritating foods, such as rice, oatmeal, baked, mashed or boiled potatoes, vegetables and finally cooked fruits are added. The indications for adding more of the irritating and bulky food are absence of intestinal distress and constipated stools. Additions to diet are stopped or even lowered somewhat whenever distress or loose stools appear. In this manner each patient is tested as to tolerance for the irritating foods and when discharged should be on a well-balanced diet which contains enough of the bulky and irritating material to produce a daily normal stool without distress and without artificial aid.

Each patient requires individual consideration and minor changes are made in the treatment as thought proper. In cases of achylia such food as meat and eggs are omitted, hydro-chloric acid is given and the intestinal powders given at such a time that they will not destroy the beneficial action of the acid. In some case of spastic colitis, the spasm is at times more easily relaxed by small doses of tincture of belladona three times daily for periods of ten days. Occasionally it is necessary to give tannic acid or opium in severe cases of diarrhea.

In some mild cases it is not necessary to institute bed rest in the initial stage of treatment. By giving the foregoing outlined diet and the intestinal powders and by a judicious use of the oil retention enemas good results are obtained with the patient up and even working at his usual occupation. However, in the majority of cases, the results are better and more quickly obtained if the initial period of hospital or home care is instituted.

In cases of the so-called "atony of the intestine," the hypo-peristaltic type, the above regime is as efficacious as in the cases of hyper-peristalsis. It is interesting to note that a careful study of many cases of the atonic or hypo-peristaltic intestine shows they have unquestionably passed through the stages of hyper-peristalsis or hypersensitive intestines and colons.

Where we have reason to suspect that part of the intestinal condition is due to an inability of the patient to properly digest carbohydrates, better results are obtained by limiting but not entirely excluding the carbohydrate intake.

Too much attention should not be placed on the slight amounts of excess mucus, fat, starch and undigested meat fibers that are so often found in the stools. It is to be expected that in a hyperperistaltic intestine and colon where the nerve endings are in a hypersensitive condition that an excess of mucus will be poured out, and when the material goes too rapidly through the intestine excesses of fat, starch and undigested meat fibers will be present. In constipation where the stools are hard there is always an excess of mucus poured out in the attempt to coat these masses and to enable them to be expelled more easily. The real cause, the disordered intestinal mechanism, should be treated, not the symptoms. Allow the normal mechanism of the intestines and colon to return and these excesses will disappear from the stools. In a similar way the bacterial flora will be improved.

Ultimate recovery is assured in these patients. They leave the hospital well nourished, free from intestinal distress and having normal stools daily without artificial aid. They are educated in the normal way in which to live and are taught to regulate the amount of bulk and irritating material in the diet, using the consistency of the stools and the absence of intestinal distress as indications for varying the amount of bulky and irritating items of diet. Patients are seldom in the hospital over three weeks and often only ten days to two weeks.

In conclusion I would place emphasis on the following:

There is a small field, if any, for the therapeutic use of artificial stimulants in the treatment of chronic intestinal disease.

The abnormal intestinal function should be recognized and aided to again become normal.

The best method is to combine physical, mental and metabolic rest with soothing treatment, allowing the intestine to regain its normal tone and reaction.

Surgeons should be more cautious in the use of artificial intestinal stimulants in the post-operative care of patients. They should insist that the normal intestinal function be re-established if it has been disturbed before allowing the patient to leave the hospital.

The general public should be better instructed as to the management of their intestinal conditions.

(Santa Barbara Clinic.)

GROUP MEDICINE—A DISCUSSION OF ITS VALUE TO THE PROFESSION AND THE PUBLIC

By DONALD J. FRICK, M. D., Los Angeles.

In the last twenty years through the advancement of knowledge by the professions and the appreciation of this by the public, it has become necessary to specialize to get the highest efficiency. In law it would be hard to find a man willing to attempt to carry a client through a criminal action, draw up articles of incorporation for a big company, pass on a bond issue and draw up a will. If you did find a man willing, you would not trust him, for you would know that he could not possibly possess the information and technique to cope successfully with all these problems. Engineering long ago developed its specialists in mining, electricity, hydraulics, construction, chemistry, etc. We take our problem to the appropriate place without question, knowing that general engineering is an impossibility. The other learned professions have kept pace of a necessity.

Medicine has had specialists in certain branches for a number of years, but only in the last few years has the human body been divided up into small sections and allocated to the different members of our profession. This is a necessity, for the capacity of one man's brain and time are unfortunately limited. With specializing in medicine have come grave problems which must in some way be solved. The correlation of the organs in the body does not allow of independent action by the different specialists without due regard to pathological conditions outside their own fields of action. The specialist cannot be a specialist and a general practitioner, so there can be no way for him to judge of conditions outside his own field except from the reports of other specialists. Unless there is organization among specialists, efficiency and time are lost to the patient and to the profession.

Keeping in mind these facts we must realize that group medicine of one type or another is a necessity. This is the reason that this subject has been under constant discussion wherever medical men have met.

Leaders in medicine, Drs. William Mayo, Billings, Barker, and others, have presented the different angles of the subject with such wisdom that a great deal that has to be said here must of necessity sound familiar and hackneyed.

Different types of groups are being worked out with more or less success. We will briefly discuss the principal types and their advantages and disadvantages.

1. Groups made up of physicians and surgeons with all the allied specialties, having common interests medically and financially.
   - (a) Built around an outstanding man.
   - (b) Built up by the association of a number of good men in a community who have succeeded in their own lines.
   - (c) Built around a college or hospital.

2, Groups who limit their work to surgery.
3. Groups who limit their work to internal medicine.
4. Diagnostic groups whose members function together for the purpose of diagnosis only.

VALUE TO THE PROFESSION

Theoretically and practically we shall have to concede that each of these types of groups is, from an educational standpoint, advantageous to the physician who is a member of the group. He cannot help being broadened by constant contact with other men, who, in a wholesome way, offer criticism upon his work.

Which of the above plans offers the most to the profession?

(1a)—The general clinic built around one man has outstanding advantages for those who are to follow the leader's bent. A great surgeon will inspire everyone about him to do the best in surgery while with him, and the fire of his genius will for all time burn in the hearts of his students. But medicine in all its branches can only take a mean position in such environment. Murphy was a maker of surgeons; Osler a maker of physicians.

(1b)—A clinic made up of a number of successful men is a great help to everyone in it, if histories are well taken, discussion of cases and results are systematically carried out, and each man gives his best to it. Unfortunately, it cannot rise above the mean between the best and poorest individual in the group. The weak man will be definitely helped, but genius will have a difficult time thriving.

(1c)—A clinic built about a college and hospital is of all types of groups the most beneficial for the profession and the members of the group. Working in a free clinic and teaching students afford the best training both for the mind and the soul. A man who cares for numbers of people with only one type of reward, the addition to his store of knowledge, grows fast and in a healthy manner. Teaching students, nurses, and physicians fixes facts in his mind and makes him careful of the source of his knowledge as nothing else does.

The financial returns from any of these types of clinics can be made adequate for all needs. Riches should neither be expected nor desired in a profession.

(2 and 3)—Medical and surgical groups are useful because they afford the members opportunity to consult with each other, to divide the expenses of a modern plant, to live and breathe like human beings rather than to be constantly on call with no respite from duty. Because if a man is a true physician, he will not undertake a case except with the belief that it is his duty to provide proper attention at all times. A group does that in the best way. Individual attention is not necessarily an advantage.

(4)—Diagnostic groups have doubtful value to the physicians who compose them. The patient goes through the mill and is sent back to his physician. The diagnosis may be correct or not. In most cases no one will ever know. The procedure is unsatisfactory and oftentimes unscientific.

VALUE TO MEDICINE

Will group medicine advance the science of medicine? Commercial group medicine can do this only along certain lines, namely, in compiling statistics from series of cases. These statistics will retard or help progress depending upon their foundation and accuracy. Careful recording of symptoms and signs in the past and present history with all the clinical data gained from the many possible means of modern diagnosis and treatment must advance our knowledge of disease. But the process has its limitations due to the necessary routine, the hurry and bustle which do not allow time for restful, constructive thought. The group in a college or endowed hospital allows periods of rest. These give the individuals time to correlate their thoughts before imparting their knowledge to others. Competition is keen in every department. Honor comes to him who advances his services above the others by the application of constructive thinking along a certain line. Medical discoveries have, as a rule, come from men who were able to concentrate along one line without being hampered by the details of routine and money-making.

VALUE TO THE PATIENT

Does group medicine offer definite advantages to the patient? It cannot be denied that all of the types are of marked value to the patient. No one can possibly specialize in all branches or become skilled in all of them. A well-balanced clinic should be able to pass a patient from one department to another rapidly, and discuss all his abnormalities. Because of bulk of work done, the best of equipment for all purposes would be available. Expert technicians in all departments under medical heads could be procured. The patient's comfort, time and pocketbook could be conserved by appropriate organization. The proper correlation and evaluation of all the facts established regarding the patient's condition, and a just decision as to treatment indicated, must be rendered by a wise and experienced head if the maximum benefit is to accrue to the patient. In our opinion, a leader of more than ordinary ability is needed in every group if the patient is to derive the greatest value from the study of his case. A patient may travel from one specialist to another in any city of moderate size and have some abnormality corrected at every stopping place, and finally come to the end of his journey little better than he was in the beginning. In the same way he may be carried through a group and the obvious abnormalities be removed, but he may be no nearer cured of his complaint than he was in the beginning, unless diagnosis and treatment are brought into unity.

Lay diagnosis has become an established custom. Dr. S. makes a careful study of Mrs. G., who has asthma. He goes over every organ, does all the foreign protein tests, the pollens, the foods, the bacteria, and finds all of them negative. He

has radiographs made of her sinuses, finds a chronic maxillary sinusitis, and is able to express pus from her tonsils. By elimination he decides that the sinusitis and chronic tonsilitis are responsible for Mrs. G.'s asthma. She is sent to a specialist, who removes her tonsils and drains her sinuses, and her asthma is cured. Mrs. G. goes along through life happily, and every asthmatic she sees she sends to a specialist for tonsillectomy and sinus drainage. In the opinion of the average specialist, not all by any means, a diseased organ that comes in his special line must come out. So Mrs. G.'s asthmatic friends usually find a willing specialist who relieves them of part of their anatomy. Occasionally one will be cured, but the seasonal asthmatic, the food-sensitive asthmatic, the cat or dog-hair asthmatic is not helped in the least, but is likely to lose faith in medicine because medical procedures in her case were not scientific.

This is not a criticism of ear, nose and throat men. It is a criticism of isolation of specialists and the treatment of organs instead of the patient. Group medicine will go a long way toward curing this situation, but it would seem wise before any procedure in a clinic is undertaken, that someone more or less versed in all phases of medicine go over the findings and decide the relative value to the patient of all remedial measures contemplated. Routine histories, physical examination, laboratory and X-ray examinations, will, of course, help guide us in solving the perplexing question of what should be done.

All three groups of the first type will be of use in eliminating the evil of isolated treatment. The last group, that connected with teaching, will do its work best, because those who teach must tell why a patient comes into the clinic and why a given procedure should benefit him. In this connection it seems possible that any group may be a teaching group if it will use the nurses in the hospital as proper students.

Medical groups and surgical groups may help distinctly if they have strength of character enough to send from their groups patients who need attention that they cannot give. Medical groups are, as a rule, dominated by diagnosticians who should have enough special help to find abnormalities. With the facts at hand, such a group can send patients to definite specialists for treatment, which, in the nature of things, should be curative or palliative for that patient. Surgical groups with the proper surgical diagnosticians can perform wonderful and lasting benefit if they will limit their sphere to constructive surgery.

DISADVANTAGES TO PATIENTS

We have discussed the advantages of group practice to the patient. Are there disadvantages? There are definite drawbacks to any of the present plans. If all physicians were molded into groups, patients would only have the choice of a group and not of a man. To be useful to a patient a group should study him thoroughly on his first appearance and then carry him along through any and all subsequent illnesses, adding to his history at his every appearance. If this were systematically done a patient would have immediate scientific care in any emergency. To make this efficient, however, he should not have his appendix removed by Dr. R. of Group A, his tonsils removed by Dr. S. of Group B, and end his surgical career by going to Dr. T. of Group C. for a prostatectomy. Drs. R., S., and T., may be the best men in their lines, but by going from one group to another he loses the efficiency gained by staying with one. Patients, however, as a rule, want the best. Group medicine of type 1 would keep them from having that at times.

The personal element in medicine would be largely eliminated. Many patients need boosting and stimulation to get well. Perplexing problems at home must be solved, and often it is only by sweeping away these worries that we may start a patient on the road to recovery.

The cost of a thorough examination by a group is proposed by some as one of the disadvantages of group practice. If any one of you will sit down and go over with one of your chronics the amount of money he has spent on different drugs and cults before even an attempt at diagnosis of his case has been made, you will realize that he ought to be willing to pay for a definite diagnosis with proper instructions for getting well. Cost can be so regulated that it will not be prohibitive to anyone.

Groups cannot take the place of the old family physician, but no man alone can do this today. In days gone by the family physician could embrace practically all of human medical knowledge and not stagger under the load. Anyone nowadays who tries to do so becomes a sorry mediocre misfit. Therefore, it has come to pass that the physician with a family practice performs all the hard work and loses the lucrative work to the specialist. The result is that only a few remain competent and clear-headed under such abuse. For one family to rely upon a single medical advisor is ideal, but not practicable.

What effect have groups on the profession at large? Groups of the 1a type (built around an outstanding man) and 1b type (made up of outstanding men in the community) become, as a rule, bones of contention if located in a city of any size. Because they are doing all kinds of work, they continually step on the toes of individual doctors. They do not refer work, so work is not referred to them. The family physician feels it most, as groups can carry families as a whole. On the other hand, type 1c, connected with a teaching hospital, is a great impetus to every doctor in the community because it holds out to him the opportunity to increase his own medical efficiency. New facts are constantly brought to the attention of those living near a group that is doing constructive work. The profession will respect the man who is giving his time to the advancement of the art of healing, and will bear him no malice.

We cannot help feeling that every section of this country would be made better by the influence of a group of medical men constructed about

a teaching, endowed hospital. Unfortunately, every community cannot be provided with such advantages, and the solution for the less fortunate communities lies in the construction of groups which will serve as well as possible the needs of its territory. Cities should strive to provide teaching hospitals. Country districts may well have groups working about a standardized hospital, the older experienced men doing the hospital work, the younger men for their first five years at least, making the outside calls and night drives, and caring for the emergencies. After these men have served their apprenticeship they may begin the study of a specialty with some basis and assurance of being really useful. The older men would be relieved of the drudgery and the science of medicine would advance decidedly in service and the respect of the people.

A liberal policy must be adopted. Sick people require better, more efficient care. Physicians need every possible means to keep abreast of the progress of medicine. Group medicine is a step forward in reaching these goals.

THE PATHOLOGY AND BACTERIOLOGY OF EXCISED TONSILS AND THE EFFECT OF X-RAY THERAPY UPON THE BACTERIAL FLORA OF TONSILS.*

By FRANKLIN R. NUZUM, M. D., Santa Barbara, Cal.

Following the report of Murphy, Witherbee and their co-workers on the effect of small doses of X-rays on hypertrophied tonsils and other lymphoid structures of the naso-pharynx much consideration has been given to this subject. A subsequent paper by Witherbee states that all of five hundred patients treated, not alone for hypertrophied tonsils, but for chronic infected tonsils, were so benefited that surgical removal was not necessary. This and similar reports have led to a debate between Roentgen therapists and nose and throat men as to the merits of X-ray therapy in tonsillar conditions.

Since the question is one of importance it seemed that a careful study of the subject by persons impartially interested in both the X-ray and the surgical side of the question would be a logical procedure in arriving at a fair conclusion.

With this in view we have undertaken a correlated study of the symptomatology of 218 patients upon whom tonsillectomy had been done and of the pathology and bacteriology of the excised tonsils. A study was then made of a smaller group of patients whose tonsils had been treated by X-ray. In this group the gross appearance of the tonsils, their change in size, and the bacterial flora before, during, and after treatment were recorded.

In recording the pathology of chronic tonsillar infections the plan of J. J. Moore has been used. He recognizes the following three pathological divisions of tonsillitis: Type 1. Chronic lacunar tonsillitis, the changes occurring in the epithelial lining of the crypts. Type 2. Chronic interstitial tonsillitis, characterized by a connective tissue increase of the stroma in the parenchyma of the organ. This type includes both atrophic fibrous tonsils and hypertrophic tonsils. In the latter, in addition to an increased stroma, there is also an increase in the number and size of the follicles, encroaching on lymphoid tissue. Type 3. Chronic peri-tonsillitis, characterized by an increase of the fibrous tissue capsule and peritonsillar tissue.

The relation between foci of infection and systemic disease has been widely recognized. The frequence and importance of streptococci as the predominant organism in such foci has likewise been emphasized. In bacteriological studies of infected tonsils, streptococci, and especially hemolytic streptococci, have assumed more prominence than other organisms.

In our study we have used the bacteriological technique advocated by J. H. Brown. Both streaked blood agar plates and poured blood agar plates were used. Single colonies were fished from these plates and transplanted on blood agar slants. Bile solubility and the use of various sugar media were employed in making a final classification of various colonies.

We have used Brown's plan of classifying streptococci. This places all streptococci into four groups, depending upon their manner of growth in blood agar plates. Alpha hemolytic streptococci are characterized by a small zone of brown or green discoloration immediately about the colony. Alpha prime hemolytic streptococci have immediately about the colony a small area of incompletely haemolized red blood cells. Beyond this is a ring of complete hemolysis. Beta haemolytic streptococci is that group which has a zone of complete haemolysis immediately about the colony. This clear zone varies from 1 to 4 mm. in width. The fourth, or final, division of streptococci are the non-haemolytic colonies. They appear as small, dark dots and produce no gross change in the adjacent blood corpuscles of the media.

There is a wide discrepancy in the frequency with which haemolytic streptococci have been reported by previous workers. A large group have reported them as present in 45 to 50 per cent of all tonsils. A small group have found them in 90 to 97 per cent. We have used both streaked and poured plates. A sterile swab was drawn across the surface of one tonsil. It was then dipped into 1 cc. of sterile physiologic salt solution. A platinum loop bent at a right angle near its distal end was then introduced into a crypt withdrawn, and dipped into a second tube containing 1 cc. of sterile physiologic salt solution. A few drops of each of these innoculated solutions were then poured into petri dishes and 12 cc. of liquid blood agar added. The petri dishes were gently agitated until the salt solution had become well mixed with the blood agar and put aside to cool, after which they were incubated for forty-eight hours. Streaked blood agar plates were made from the same material and incubated.

* From the Clinic of the Santa Barbara Cottage Hospital.

The plates were read at the end of 24 and 48 hours, and further work was done, as previously indicated in identifying the individual colonies of organisms.

Table I gives a comparison of the findings as between streaked and poured plates. From this it is apparent that in streaked plates rapidly growing organisms, such as staphlococci, prevent the recognition of other organisms, especially haemolytic streptococci and pneumococci. Further, the type of haemolysis can be more satisfactorily determined in poured plates. Ring formation, which occasionally occurs in Alpha type haemolytic streptococci following repeated incubation and ice-box refrigeration, was seldom detected in streaked plates, whereas it was present in 5 per cent of the cultures in which Alpha organisms occurred and poured plates were used.

TABLE I

	Streaked Plate %	Poured Plate %
Haemolytic streptococci, all types	45	96.1
Non-haemolytic streptococci	3.5	2.6
Staphylococci	64	37
Pneumococci	18	40.8
Bacilli	7	1.9

We found haemolytic streptococci in 96.1 per cent of the tonsils cultured. This is in accord with recent publications; among others, one by D. J. Davis, who reported them in 97 per cent of all tonsils, and one by Pilot and Pearlman, who found them in 95 per cent of excised tonsils. A majority of the writers who have reported haemolytic streptococci as present in 35 to 50 per cent of tonsils, used the streaked plate method, and in the light of our work this explains the discrepancy.

The clinical reason for removing the tonsils in our group of patients and the type of organism found on culture following removal are given in Table II.

TABLE II

	Alpha %	Alpha Prime %	Beta %	All Types Haem Strep. %	Gamma %	Bacilli %	Staphylococci and other organisms %
Tonsillitis	5	2.5	76	83.5	1.5	5	10
Mouth Breathing	11	..	81	92	..	8	..
Frequent Colds	8	10	61	79	..	10	11
Otitis Media	..	..	100	100	..	..	..
Rheumatism	18.5	..	54.6	73.1	9	9	9
Pathological tonsils	8.5	2.5	74.5	85.5	2.1	6.4	6
Normal tonsils	14	..	14	28	..	14	58

Haemolytic streptococci as the predominating organism were found in from 73 to 100 per cent of the tonsils removed for the various indicated reasons. In acute tonsillitis they were the causative organism in 83.5 per cent. In patients with rheumatism who were judged to have infected tonsils Beta haemolytic streptococci were present in 54.6 per cent and Alpha haemolytic streptococci were present in 18.5 per cent. Alpha haemolytic streptococci are more commonly known as streptococci viridans; they were found more frequently in the group of tonsils of patients with rheumatism than in any other. Of the entire group of tonsils which, after microscopic study, were judged to be pathologic, 85.5 per cent had, as the predominating organisms, haemolytic streptococci. Of the 15 tonsils in this group of 218, which on microscopic study gave no evidence of pathology, haemolytic streptococci were found in but 28 per cent and staphylococci and other organisms in 72 per cent.

Of the three groups of haemolytic streptococci the Beta, that group surrounded by a zone of complete haemolysis, is found much more frequently than Alpha or Alpha prime colonies. The area of haemolysis about the Beta colonies was designated as of wide zone when the width of the zone measured 4 mm. Frequently the zone measured 1 to 2 mm. in width, and these were designated as narrow zone. This width of zone seemed to be fairly constant and an effort was made to demonstrate further differences between them. The fermentations of various sugars resulted, as shown in Table III.

TABLE III

	Saccharine	Lactose	Raffinose	Salicin	Mannite	Inulin
Wide Zone	+	+	0	+	0	0
Nar'w Zone	+	+	0	+	0	0

Both types were virulent when injected into rabbits. When repeatedly subcultured the narrow zone group was found to become a wide zone type and vice versa. For these various reasons it was assumed that the amount of haemolysis depends upon the amount of streptolysin produced and that there is no further difference between these Beta colonies.

Table IV reviews the pathology of the excised tonsils, using Moore's classification. Changes were most frequently found about the crypts and occurred in patients who gave a history of attacks of tonsillitis. Chronic interstitial tonsils were present in 21 per cent of all of the tonsils examined. Of the group of patients who had complained of rheumatism, 66 per cent had pathologic changes in their tonsils of this type. Chronic peritonsillitis was present in 8 per cent of all tonsils examined and occurred most frequently in the tonsils of patients who had had rheumatism.

TABLE IV

	%
Chronic lacunar tonsillitis	42
Chronic interstitial tonsillitis	21
Chronic peri-tonsillitis	8
Abscesses	10
Lymphatic hyperplasia (as only change)	14
Mucous glands in capsule	7
Cartilage in capsule	3

The second group of patients in our study were said clinically to have hypertrophied or infected tonsils. They were given X-ray therapy. The technic as suggested by Witherbee was used. Since only 32 patients have received this method of therapy it would be unjust to draw definite conclusions. In the original report of Witherbee 40 patients were treated. Cultures from the crypts of these tonsils demonstrated haemolytic streptococci in each instance. The type of haemolytic streptococci was not stated. Following the X-ray therapy the tonsils became smaller and haemolytic streptococci were found in but four of the entire series. A second series of 500 patients reported later by the same writer leads one to believe that as a result of the shrinkage of the lymphoid tissue in the tonsils the crypts became everted, emptied themselves, and the patient was rid of his ton-

sillar infection. This work was not checked bacteriologically.

In this series of thirty-two patients cultures were made at the time of each treatment and at an interval following the final exposure. From four to twelve treatments were given each patient. In 16 per cent large hypertrophied tonsils shrank to a very small size. The crypts drained completely. The tonsil had a plain, smooth surface. Cultures from these tonsils were negative for all types of haemolytic streptococci. Thirty-four per cent of the remaining tonsils did not alter materially in size or gross appearance, but cultures from the surface and crypts became negative for all types of haemolytic streptococci and remained so. The remaining 50 per cent were not altered grossly and haemolytic streptococci of the Alpha and Beta types persisted in cultures made from surface and crypt.

A much larger series should be studied in the manner outlined before final conclusions are justified. But insofar as we have carried out this work the tonsil has not been rid of its latent infection, as represented by haemolytic streptococci, in anywhere near the proportion of instances that other reports in the literature indicate.

CONCLUSIONS.

Seven per cent of 218 pairs of tonsils removed presented no microscopic evidence of disease.

Ninety-six and one-tenth per cent of this group of 218 tonsils harbored haemolytic streptococci.

Of the three groups of haemolytic streptococci, Alpha, Alpha prime and Beta, the latter were found much more frequently.

There seemed to be a relation between the pathology of the excised tonsil and the type of organism it harbored.

Poured plates were found much more satisfactory than streaked plates.

X-ray therapy was effective in reducing the size of tonsils in but 16 per cent of this series.

Haemolytic streptococci, the essential organisms in chronically infected tonsils, were permanently removed in but 50 per cent of the patients treated.

Safe Hypnosis—When the physician finds it necessary to prescribe a hypnotic, two questions occur to him: Is it safe? Will it induce a drug habit? If safe, it will put the patient to sleep without risk of immediate or subsequent reaction involving pain or injury of any kind. If non-habit-forming it may be administered as often as the condition of the patient requires, or discontinued at any time without any more inconvenience to the patient than if it had never been taken.

These conditions are said to be perfectly fulfilled in Chloretone, a Parke, Davis & Co. product, which acts upon the dentritic processes in the brain, relaxing them so that both sensory and motor impulses are inhibited. This effect disappears gradually without, apparently, any more alteration in the functions of the nerve filaments than that which follows the sleep of ordinary fatigue.

Chloretone is given for its hypnotic effect in a dose of 5 grains, to be repeated, if necessary, in half an hour, and at this interval, in exceptional cases, up to 20 or 25 grains. It is indicated in the insomnia of excitement, in sthenic cases only.

THE MODERN HOSPITAL ON THE PACIFIC COAST *

By J. B. CUTTER, M. D., Watsonville, Cal.

As it has been truly said, "With the best of good-will concentrated on hospitals, in countries most advanced in the arts of civilization, it has taken centuries of unflagging effort to lift hospitals to a position of safety and desirability. It was still a question sixty years ago, whether the establishment of hospitals in such countries as England and France was an event fraught with good or evil. In our own day the good accomplished by hospitals is not a subject of dispute. Nevertheless, the precise place a hospital should occupy in the body politic, the proper seat of responsibility for its existence and work and the principles of its organization, remain fruitful subjects of investigation and debate.

W. H. Smith, in discussing this subject, says: "The hospital is now looked upon as an essential public service institution. It is the place of first resort in sickness or injury of any very acute or serious nature; but the hospital provides for the poor and well-to-do, but makes no special provision for that large class of persons of moderate means who do not want charity, but who can neither afford the expensive private service, nor bring themselves to accept the conditions of the charity ward. . . . The status of the hospital administrator must be clearly understood, else we shall have no administrator worthy of the name. Hospital administration is a specialty, and an important one in our scheme of hospital development."

Referring further to the same subject, Ray Lyman Wilbur says: "There are two general problems involved; first, the development of high-grade administrators, with a medical education, who can serve as leaders of medical education, and public health. When suited for it their positions should be dignified, and opportunity should be given to them to be influential in the whole public health movement, in medical education, and in furthering the progress of medical knowledge."

There is hope that the lot of the hospital administrator and medical economist may become more attractive. In the judgment of many it is important in the successful development of our larger hospitals, that the medical men of the best type and ability should enter this field.

During thirty years' association with hospitals on the Pacific Coast, I have experienced the vicissitudes of many hospitals in an administrative capacity. Until the last decade their standing has been low in the scale of modern hospital excellence. Fifteen years ago I entered the field of hospital activities in one of the larger cities of California, with an earnest desire to take some part in helping to accomplish what I see being accomplished now. At that time it was an admitted fact by the leading men of the profession of that place that there was but one hospital in that city

* Read before the Santa Cruz County Medical Society, at its meeting held in Santa Cruz March 6, 1922.

that did not place profits above good service and good name; that hospital was managed by the Sisters of the Catholic Church.

Today the situation is different, and I believe, through the activities of the committee for hospital betterment of the League for the Conservation of Public Health, of which Dr. Musgrave is the chairman, and which also represents the hospital interests and plans in California of the American Medical Association, that state of affairs no longer exists.

California is branching out with full impetus in the new hospital movement. Modern hospitals are being built or being planned in many progressive towns. While as yet these communities are not educated up to the point of filling their subscription lists with substantial voluntary gifts seen in older communities, we do have the encouraging example of a nearby community where within the past year subscriptions of a quarter of a million have been made under the stipulated agreement that not more than 7 per cent interest should be paid on certificates of stock, and as high as $35,000 has been given outright to the hospital in a single subscription.

This is decidedly a step in advance from the position of a leading hospital in a neighboring city, where the boast was made of payments of dividends on stock of 24 per cent only a few years ago. Under the present plan and influences of an organized medical profession it need not be feared that these new hospitals will not square in all particulars of organization and administration with the best hospital traditions of the State and of the country.

In one community in New England of 11,500 population, with an adjacent population of 20,000 it was decided to build a community hospital, and the sum necessary was placed at $225,000. In order to meet the difficult task of raising this money an organization was effected, an office was opened, and the preparatory work of the director and his staff was begun. It was realized that the success of the undertaking depended upon the thorough education of the public in the necessity of a modern hospital. The Chamber of Commerce, Women's Club, and other organizations passed resolutions endorsing the undertaking and urged the public to support the movement to raise the $225,000. After thorough preparation for the campaign to raise the money subscription lists were opened, and on the first day of the returns $50,000 was subscribed. The final report, after a vigorous campaign of several weeks, showed that $273,465 had been *given* by 4862 subscribers.

What was regarded as remarkable by the several hundred public spirited citizens, men and women who raised the fund with its 21½ per cent oversubscription, as one of the most gratifying features of the undertaking, is the fact that throughout the movement there was not a single evidence of the use of coercive measures to obtain subscriptions. The hospital, as a result of thus going frankly before the people in the manner indicated, has gained at least four thousand new supporters, who subscribed liberally, but the hospital succeeded in convincing them by facts alone that it is an institution that merited their support.

"The handling of hospital funds and the operating of a hospital is a sacred trust"; this I have always maintained, and entails a degree of obligation far in excess of the handling of most funds.

Communities contribute of their funds to hospitals because they have faith in the efficiency of these hospitals and because they believe they are assisting in a wonderful work. It is incumbent upon the administration of hospitals to conduct their business so that the trust is not misplaced, and this cannot be accomplished without accurately recording all the activities of the hospial.

What a contrast today with the condition in the eighteenth century, when many new hospitals were built, but in respect of cleanliness and administration these institutions sunk to the lowest level known in the history of medicine. "The Modern Hospital" says editorially that "Hospitals, more than any other institution today, have within their grasp the opportunity to dignify human life; that is one of the largest parts of their social service. Will they do it? Upon the occasion of the celebration of the one hundred and fiftieth anniversary of the founding of the New York Hospital, Hon. Elihu Root, long a member of the Board of Governors of the Hospital Society, made the following remarks in the course of his address.

"But I think there is something besides the curing of disease or the advancement of science, something that is broader than that, broader than any of these. All the terrible lessons of the last decade show clearly that the most insuperable obstacle to the peace and happiness and progress and growth of a people is their incapacity to receive the blessings that are ready for them if they will but take them. The world is full of murder and hatred and strife today, because of the incapacity of millions of people in organized States to receive the truth that is being spread, and has spread, throughout our higher forms of civilization and which is to be theirs in centuries to come, but they are not ready for it now.

"This is not a matter of intellectual power, it is not a matter of learning, it is not a matter of precept, it is a matter of the development of character. All the sermons ever preached, all the orations ever delivered, all the books ever printed, working through the brain of man, cannot create in him the highest qualities that man is capable of. The development of character must come through exercise by men themselves of the virtues that make human character, mercy, compassion, kindly consideration, brotherly affection, sympathy with fellowmen, unselfish willingness to sacrifice for others."

As love of service to humanity animated those who founded the first hospitals in this country, and many who have followed them, it must animate those who create and operate a modern hospital.

EDITORIALS

RAY LYMAN WILBUR

In selecting Ray Lyman Wilbur President-Elect of the A. M. A., our National Association, in addition to conferring upon Dr. Wilbur the greatest honor within the gift of the physicians of the United States, has honored our State, a great medical school and every physician of California.

Members of the Medical Society of California are greatly pleased with Dr. Wilbur's election, and on their behalf and in their names we congratulate him and pledge him our full co-operation and support in making a striking success of the 1923 meeting of the A. M. A.

Dr. Wilbur's conspicuous services in the cause of better medicine and better public health are reviewed in an editorial in the Journal of the A. M. A. of June 3, 1922.

THE 1923 MEETING OF THE A. M. A.

The 1923 meeting of the A. M. A. is to be held in San Francisco, June 25-29.

The privilege and honor of entertaining this the greatest of all medical organizations was won by the earnest endeavors of the San Francisco Convention and Tourist League and of our own delegates who attended the meeting, C. Van Zwalenburg, Albert Soiland, Victor G. Vecki and E. C. Fleischner, are to be congratulated on their splendid representation of our Society's affairs at the National Convention. They were ably seconded in their efforts by the delegates from other western States, and particularly by the enthusiastic support of J. A. Pettit of Oregon.

As hosts for the A. M. A., California, and the Medical Society in particular, have accepted an important and serious responsibility. With all the agencies interested in the medical welfare of the State working effectively and in harmony, the 1923 meeting can be made a memorable one.

The Council of the State Medical Society will give consideration to the problems involved at its meeting in Los Angeles the first week in September. There will be plenty to do for all who are willing to work. It is not too much to hope for the full co-operation and assistance of our members in preparing and executing plans that will make this the banner meeting of our National Association.

OPERATING WITHOUT PERMISSION

Hospitals and physicians throughout the State should learn one lesson at least from the undesirable publicity in which the San Francisco Hospital finds itself involved. There seems to be no question whatsoever but what performing an operation without proper permission from the patient or the person responsible for the patient, in case of a minor, is a violation of the law in California. Physicians and hospitals, whatever their private opinions may be, should be law-abiding in all of their actions.

The dangers connected with violation of this particular law have been emphasized a number of times in the Journal, in Better Health and wherever medical societies meet.

The League for the Conservation of Public Health, with the approval of the Council of the State Medical Society, has issued a form for permit to operate, which has been reviewed by our attorneys and which complies with the law in every respect. Samples of these forms will be issued to any hospital or physician requesting them.

Any hospital that does not absolutely prohibit any sort of an operation within its walls, or even the giving of an anesthetic preparatory to operation, without a properly worded written permit is pursuing a hazardous course and one that is illegal as well.

HOSPITAL CONVENTION

The second annual convention of the hospitals of California will be held under the auspices of the League for the Conservation of Public Health on Tuesday to Friday, September 5 to 8, at the Maryland Hotel in Pasadena.

On Friday, September 8, the Council of the State Medical Society will hold two meetings at the Maryland Hotel. One meeting will be at 10 a. m. and the other at 8 p. m.

On Saturday, September 9, the Council of the State Medical Society will meet with the presidents and secretaries of all County Medical Societies. This meeting will open with a luncheon at the hotel and continue until the program has been disposed of.

These combined meetings will bring together large numbers of persons interested in all phases of medical, hospital and public health betterment. Monday, September 4, and Saturday, September 9, are holidays. Very attractive rates and facilities have been arranged for at the Maryland Hotel, and all persons interested in any phase of hospital work are cordially invited to plan to spend the first week of September at the convention.

The program for the hospital convention is now in course of preparation. It will be carried out along the same general lines that made the convention last year so successful. All physicians, trustees, directors, administrators, nurses, technicians, record secretaries, and other persons interested in hospitals should be present at this meeting and take part in the discussions.

Dr. Charles D. Lockwood, 295 Markham place, Pasadena, is chairman of the committee of arrangements. This committee, the hotels, the Chamber of Commerce and other civic organizations are at work upon plans to make the social and recreational features of the convention attractive.

See the August numbers of the JOURNAL and of Better Health for further publicity.

For reservations, address Mr. H. M. Nickerson, Resident Manager, Hotel Maryland, Pasadena, California.

STATE SOCIETY

MINUTES OF THE HOUSE OF DELEGATES, THE FIFTY-FIRST ANNUAL SESSION OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA.

FIRST SESSION

Held at Yosemite National Park, Monday evening, May 15, 1922, at 8 o'clock

Roll-call—Seventy-three (73) delegates were seated, and the president, John H. Graves, declared a quorum present.

Report of the President—The report of the president having been presented to the General Sessions was considered presented to this body. (For the full text of this report, see the June number of the Journal.)

Appointment of the Reference Committee—The president appointed the following Reference Committee: James H. Parkinson, Sacramento, chairman; Howard Morrow, San Francisco; Charles D. Lockwood, Pasadena, and Hartley F. Peart, General Counsel of the Society, ex-officio.

Report of the Council—The president announced that the chairman of the Council, Dr. Kenyon, was ill, and called upon Dr. Bine to make the report of the Council:

Because of the absence of Dr. Kenyon, I was asked but a few minutes ago, to address this meeting. One of the things that I would particularly like to emphasize is the sorrow of the Council in not having Dr. Kenyon with us tonight. It is more than twenty years ago that Dr. Kenyon first became a member of the Council of the State Society. In all that time he has never failed to attend one of its meetings, and this House of Delegates, I feel, should pass a resolution commending the work of Dr. Kenyon.

The work of the Council has been so voluminous that it is impossible for me, on short notice, to give you a proper presentation of its activities. A good deal of its time during the past year has been devoted to the problem of industrial accident work. One of its committees, in particular, has made a special study of this subject and its report was presented at the general meeting this morning.

The legal problems of the Society have required many hours of consideration. You will pardon me if I dwell upon this work, but I feel that, in spite of all that Mr. Peart has done to bring this matter before the County Societies and their members, a large majority of the members do not appreciate the situation. The Council is familiar with every case that comes before the legal department. It stands back of Mr. Peart and the Society's members at all times. No one can tell when his hour of worry, trial and tribulations may come. Some medical men and specialists feel that it is only the surgeons who may get sued, but the files of the legal department indicate otherwise. Many a physician believes that he is immune; suddenly a summons appears and then the individual wakes up to realize that he is absolutely unfamiliar with the work of the legal department, his rights and his duties; and occasionally by his actions complicates the matter of his defense.

The cost of the legal department is a matter of considerable importance. We pay much less for our medical defense than do individuals who carry insurance in the old-line companies. One of the companies has increased its premiums to $75 a year. During 1921 the medical defense cost our Society about $17,500, or about $5 per member. In order to meet this expense we shall be obliged to raise our dues though a majority of the members of the Council feel the increase should be greater than the two dollars proposed.

One rather important step was taken last year when a large and successful meeting of the presidents and secretaries of the county societies was held in San Francisco with the Council and officers of the State Society. Very much good was accomplished by this meeting.

There is another piece of work to which the Council wishes to call your attention. For many years the Council has been hoping to get access to the columns of the lay press in order to educate the public along medical lines. Finally an opportunity came when one of the San Francisco papers agreed to publish a series of articles. This matter was referred to the League for the Conservation of Public Health, and articles that have been published have attracted widespread attention. In fact, one of the Los Angeles papers is now conducting a similar column, and several other newspapers in this State have been trying to follow suit. The matter, however, is not a simple one and, without the backing of the League for the Conservation of Public Health and the Society, they cannot succeed. The Council feels that these health columns are a very valuable means for reaching the public.

Report of the Committee on Scientific Program—The secretary, as chairman ex-officio of the Committee on Scientific Program, submitted the following report:

The activities of the Committee on Scientific Program are shown in the complete program of the meeting which was published in the May number of the California State Journal of Medicine.

The Program Committee wishes to call the attention of all members to a ruling of the Council by which the officers of the various sections are responsible for the scientific programs of their sections. The committee of the State Society on scientific program by the same ruling fixes the number, time and place of the meetings of the various sections, and uses its good offices to promote harmony and co-ordination between the activities of the various sections.

Report of the Auditing Committee—The report of the auditing committee and the firm of certified public accountants, who officially audit the accounts of the Society once a year, having been previously passed upon and approved by the Council of the State Society, was submitted to the House of Delegates and accepted by that body.

Report of the Committee on Expert Medical Testimony—The committee submitted no report.

Report of Committee on Local and State Expenditures for Medical and Sanitary Measures—The committee submitted no report, and was ordered continued.

Report of Committee on Codification of Constitution and By-Laws of the Medical Society of the State of California—The committee, consisting of the attorney and secretary of the State Society submitted a proposed codification of the constitution and by-laws, which was referred to the reference committee without reading, inasmuch as the constitution provides that these amendments must be published twice during the year in the Journal of the Society.

Report of the Committee on Industrial Accident Insurance—The report was presented at the General Sessions by the chairman, James H. Parkinson, and is considered presented to this body. For complete text of this report, see minutes of second session.

Additional comment made by Dr. Parkinson as chairman is also published in this issue of the Journal on page 222.

Report of the Secretary-Editor—W. E. Musgrave, secretary-editor, submitted the following report:

President Graves in his address this morning and Dr. Bine in the report of the Council have covered the major activities of the Society. There are a few things I would like to have you think about: California is very fortunate in having three good medical schools. This, with the other advantages in medical matters, ought to make us a great medical center. We are not availing ourselves fully of the opportunities thus offered. What are we going to do about it?

Our Society is over fifty years old. We still have only approximately 50 per cent of the eligible physicians of the state in our membership. There are about 6900 licensed physicians in California and there are about 3500 of them members of this Society. What are we going to do about that? What can we hope to do when some commercial enterprise not interested in quality of professional work says: "I don't care a d—— about the State Society; I can get all the doctors I want from among those duly licensed but not members of your Society to accept my proposition." When our membership includes at least 90 per cent of the eligible physicians, and all members act in accordance with the wishes of the majority, we can do many things worth while for both the public and the profession. Eligible physicians who are not members ought to be made to realize that others are carrying the burden and cost of service for all.

These things are commended to your serious consideration, and at the same time you are invited to review the consequences of failure to improve our organization in numbers and team-work among the members.

Report of the Legal Department—The report of the Legal Department was presented by general attorney, Hartley F. Peart, at the general sessions, and is considered presented to this body and will

be referred to the reference committee. (The report will be published in an early number of the Journal.)

Unfinished Business—There was no unfinished business to come before the meeting.

New Business—In accordance with the rules of the Society, the following resolutions were presented and referred to the Reference Committee:

Resolution No. 1. Rate Cutting in Industrial Accident Insurance Work—Presented by the Section on Industrial Medicine and Surgery, through the Council. For text of resolution and final action by the House of Delegates see minutes of the Second Session.

Resolution No. 2. California Association of Radiographers—Presented by Dr. Sol Hyman. For text of resolution and final action by the House of Delegates see minutes of the Second Session.

Resolution No. 3. Uniformity in Medical Fees—Presented by E. F. Reamer, delegate from Stanislaus County Medical Society. For text of resolution and final action by the House of Delegates see minutes of the Second Session.

Resolution No. 4. Director of State Institutions—Presented by San Joaquin County Medical Society. For text of resolution and final action by the House of Delegates see minutes of the Second Session.

Resolution No. 5. Exceptions to State License Requirements—Presented by Council of the State Society. For text of resolution and final action see minutes of Second Session.

Resolution No. 6. Instruction of Delegates to A. M. A.—Presented by the Council. For text of resolution and final action see minutes of Second Session.

Resolution No. 7. A. M. A. Meeting for 1923—Presented by the Council. For text of resolution and final action see minutes of Second Session.

Resolution No. 8. Better Health Service—Presented by the Council. For text of resolution and final action see minutes of Second Session.

Resolution No. 9—Health Centers—Presented by the Council. For text of resolution and final action see minutes of Second Session.

Resolution No. 10. Extension of Better Health Service—Presented by the Council. For text of resolution and final action see minutes of Second Session.

Resolution No. 11. Annual Dues—Presented by the Council. For text of resolution and final action see minutes of Second Session.

Resolution No. 12. Provision for Segregating Expenses and Method of Providing Medical Defense—Presented by the Council. For text of resolution and final action see minutes of Second Session.

Resolution No. 13. Indemnity Defense Fund Assessment—Presented by the Council. For text of resolution and final action see minutes of Second Session.

Adjournment—There being no further business, the meeting adjourned to meet Wednesday evening, May 17, 1922, at the same time and place.

SECOND SESSION

Wednesday Evening, May 17, 1922

The roll being called, seventy (70) delegates were found to be present, and the president, John H. Graves, declared a quorum present.

Place of Meeting, 1923—The secretary announced that by unanimous action of the Council, the invitation of the San Francisco Convention and Tourist League has been accepted, to hold the 1923 meeting in San Francisco in the Civic Auditorium.

Election of Officers

President-Elect—T. C. Edwards of Salinas, Monterey County, was nominated for President-Elect by Saxton T. Pope of San Francisco. The nomination was seconded by W. T. McArthur of Los Angeles. Acting under authority of a positive motion, the secretary cast the ballot, and T. C. Edwards was declared elected President-Elect of the Society for the year 1922.

First Vice-President—Percy T. Magan of Los Angeles was nominated for First Vice-President by Charles D. Lockwood of Pasadena. The nomination was seconded by W. W. Beckett of Los Angeles. Acting under authority of a positive motion, the secretary cast the ballot, and Percy T. Magan was declared elected First Vice-President for the ensuing year.

Second Vice-President—W. W. Cross of Fresno was nominated for Second Vice-President by G. W. Walker of Fresno. The nomination was seconded by Rene Bine of San Francisco. Acting under authority of a positive motion, the secretary cast the ballot, and W. W. Cross was declared elected Second Vice-President.

Secretary—W. E. Musgrave of San Francisco was nominated for Secretary by George H. Kress of Los Angeles. The nomination was seconded by W. W. Beckett of Los Angeles. Acting under authority of a positive motion, the president cast the ballot, and W. E. Musgrave was declared elected Secretary for the ensuing year.

Councilors

Second District—William H. Kiger was nominated by Harlan Shoemaker of Los Angeles for Councilor for the Second District, said nomination being seconded by Donald J. Frick of Los Angeles. Acting under authority of a positive motion, the secretary cast the ballot, and William H. Kiger was declared elected Councilor for the Second District for the ensuing three years, to succeed himself.

Fourth District—Fred R. De Lappe of Modesto was nominated by W. W. Cross of Fresno for Councilor for the Fourth District, said nomination being seconded by Saxton T. Pope of San Francisco. Acting under authority of a positive motion, the secretary cast the ballot, and Fred R. De Lappe was declared elected Councilor for the Fourth District for the ensuing three years, to succeed himself.

Sixth District—C. G. Kenyon of San Francisco was nominated by James H. Parkinson of Sacramento for Councilor for the Sixth District, said nomination being seconded by Rene Bine of San Francisco. Acting under authority of a positive motion, the secretary cast the ballot, and C. G. Kenyon was declared elected Councilor for the Sixth District for the ensuing three years, to succeed himself.

Eighth District—James H. Parkinson of Sacramento was nominated by E. T. Rulison of Sacramento for Councilor for the Eighth District, said nomination being seconded by E. C. Turner of Sacramento. Acting under authority of a positive motion, the secretary cast the ballot, and James H. Parkinson was declared elected Councilor for the Eighth District for the ensuing three years, to succeed himself.

At Large—O. D. Hamlin of Oakland was nominated by L. P. Adams of Oakland for Councilor-at-Large, said nomination being seconded by P. T. Phillips of Santa Cruz. Acting under authority of a positive motion, the secretary cast the ballot, and O. D. Hamlin was declared elected Councilor-at-Large for the ensuing three years, to succeed himself.

Member of Committee on Scientific Program—Lemuel P. Adams of Oakland was nominated by P. T. Phillips of Santa Cruz, a member of the Committee on Scientific Program, said nomination being duly seconded by John C. Yates of San Diego. Acting under authority of a positive motion, the secretary cast the ballot, and Lemuel P. Adams was declared elected a member of the Committee on Scientific Program for the ensuing four years, to succeed himself.

Delegates to the American Medical Association—The Council, having discussed the situation regarding delegates and alternates to the American Medical Association, the secretary was instructed to bring before the House of Delegates a clean slate, with the request that the House of Delegates proceed to the election of two delegates, with their corresponding alternates, to act for two years (1922 and 1923); and the election of two delegates, with their corresponding alternates, to act for one year (1922), in order to conform to the by-laws of the A. M. A.

Upon motion of Walter V. Brem of Los Angeles, regularly seconded, Charles D. Lockwood

of Pasadena was nominated for Delegate to the A. M. A. for a two-year term. Acting under authority of a positive motion, the secretary was instructed to cast the ballot, and Charles D. Lockwood was declared elected Delegate to the A. M. A. for a two-year term.

Upon motion of George H. Kress of Los Angeles, seconded by Harry J. Spiro of San Francisco, Victor G. Vecki was nominated for Delegate to the A. M. A. for a two-year term. Acting under authority of a positive motion, the secretary was instructed to cast the ballot, and Victor G. Vecki was declared elected Delegate to the A. M. A. for a two-year term.

Upon motion of Charles D. Lockwood of Pasadena, seconded by Rene Bine of San Francisco, C. Van Zwalenburg of Riverside was nominated Delegate to the A. M. A. for a one-year term. Acting under authority of a positive motion, the secretary was instructed to cast the ballot, and C. Van Zwalenburg was declared elected Delegate to the A. M. A. for a one-year term.

Upon motion of Rene Bine of San Francisco, seconded by Saxton T. Pope of San Francisco, E. C. Fleischner of San Francisco was nominated for Delegate to the A. M. A. for a one-year term. Acting under authority of a positive motion, the secretary was instructed to cast the ballot, and E. C. Fleischner was declared elected Delegate to the A. M. A. for a one-year term.

Alternates to the American Medical Association—Upon motion of Donald J. Frick, seconded by Rene Bine, Walter V. Brem of Los Angeles was nominated for Alternate to Charles D. Lockwood. Acting under authority of a positive motion, the secretary cast the ballot, and Walter V. Brem was declared elected Alternate for Charles D. Lockwood for two years.

Upon motion of Dow H. Ransom of Madera, seconded by Saxton T. Pope, Harry J. Spiro of San Francisco was nominated for Alternate to Victor G. Vecki. Acting under authority of a positive motion, the secretary cast the ballot, and Harry J. Spiro was declared elected Alternate for Victor G. Vecki for two years.

Upon motion of W. T. McArthur, seconded by Percy T. Magan, Albert Soiland of Los Angeles was nominated for Alternate to C. Van Zwalenburg. Acting under authority of a positive motion, the secretary cast the ballot, and Albert Soiland was declared elected Alternate for C. Van Zwalenburg for one year.

Upon motion of Saxton T. Pope, seconded by Rene Bine, Walter C. Alvarez of San Francisco was nominated for Alternate for E. C. Fleischner. Acting under authority of a positive motion, the secretary cast the ballot, and Walter C. Alvarez was declared elected Alternate for E. C. Fleischner for one year.

Delegates to the A. M. A., with their corresponding alternates, are as follows:

Charles D. Lockwood, Pasadena, 1922 and 1923; Alternate, Walter V. Brem, Los Angeles, 1922 and 1923.

Victor G. Vecki, San Francisco, 1922 and 1923; Alternate, Harry J. Spiro, San Francisco, 1922 and 1923.

C. Van Zwalenburg, Riverside, 1922; Alternate, Albert Soiland, Los Angeles, 1922.

E. C. Fleischner, San Francisco, 1922; Alternate, Walter C. Alvarez, San Francisco, 1922.

REPORT OF THE REFERENCE COMMITTEE

James H. Parkinson, chairman of the Reference Committee, reported as follows for the committee:

1. **President's Address**—

(a) **Indemnity Defense Fund**—The committee recommends that every member of the Society who regards himself as in active practice become a member of the Indemnity Defense Fund.

(b) **Medical Education**—The committee recommends that each County Society provide for the presentation annually of a paper on medical edution by one of its members not engaged in teaching.

(c) **Lay Medical Activities**—The committee recommends that physicians in every community carefully study suggested medical activities emanating from sources outside the profession before affiliating themselves with them, especially upon a gratuitous basis.

Upon motion duly made and seconded, it was unanimously resolved that the report of the committee, upon the president's recommendations, be accepted and referred to the Council with authority to act.

2. **Report of the Committee on Industrial Accident Insurance**—The text of the report is as follows:

The report of the committee at the San Diego meeting in 1921 stated that the new fee schedule had become effective in June of the previous year, and that the forms for reports had been issued and were being adopted by the insurance companies.

The question of a further increase in the fee schedule was believed to be inadvisable and the committee still believes that no advance should be sought at this time.

The formation of a permanent committee of adjustment was strongly recommended as a valuable factor in eliminating trouble between the profession and the carriers. It was felt that such a committee could insure the payment of all reasonable claims, thus incidentally increasing the general standard of remuneration.

The necessary expense that must be incurred in the establishment and operation of such a committee was regarded as beyond the resources of the society. The hope was expressed that a full time secretary could accomplish something along these lines and, at the same time, get some idea of the possible volume of business that might be transacted.

Two propositions were submitted for discussion and action: The flat fee originally advocated by Dr. Graves and the enlargement of the so-called panel. The report was unanimously adopted by the society.

The committee has held fewer meetings during the past year and much of the detail work in signing up companies on the fee schedule and in extending adoption of the report blanks has been done through the secretary's office. Our attorney here, as always, has been of invaluable assistance and steady progress has been made.

It may seem rather an ambitious project to have the California blank generally adopted as a standard form for all compensation carriers. There is no reason whatever why a standard form, even of simpler character, should not be in general use. It would simplify business, promote accuracy and save a great deal of correspondence. Purely as an economic measure, it offers great possibility, and from this standpoint it should be pushed with the companies.

The two propositions already mentioned were taken up by the committee, but, as the flat fee

in a measure was directly related to a revised fee schedule and should be discussed in relation thereto, it was dropped for the present.

The question of enlargement of the panel was quite exhaustively discussed by the committee at its meetings and at conferences with the secretary and the attorney. It was finally decided to submit a report of a general character requesting the various county societies to certify panels, but omitting all references to plans or methods by which this should be accomplished. This course was adopted as the question was manifestly a very difficulty one to deal with. The report is as follows:

THE REPORT AS AMENDED AND FINALLY ADOPTED

Adoption of Blanks and Fee Schedule—The committee requests that it be authorized to hold conferences with insurance companies and with individual representatives of same, to secure the general adoption of the Society's blanks which automatically adopts the fee schedule.

Increase in Fees—The committee believes conditions at present are inopportune for seeking an increase in the present fee schedule and recommends that action be deferred until prices have been stabilized and the business outlook improves.

Enlargement of the Panel—In line with its former suggestions the committee believes steps should at once be taken to enlarge the panel. It recognizes that, while many physicians believe the injured employe should have the right to choose his medical attendant, this right cannot be conceded by those legally responsible for his care and legally liable for every expense attached thereto. At the same time there is no reason why men competent to do surgical work and to make the necessary reports should not be permitted to treat all cases referred to them by employers.

The question of professional competence is not based upon personal preference, nor can it with certainty be determined by a layman nor, indeed, by an insurance company not employing a medical director. The medical profession is the only judge of the qualifications of its members and their efficiency in the various specialties.

The committee, therefore, recommends that various County Societies be requested to assume this responsibility toward the State and that each society be instructed to certify to the Secretary of the State Society a list of its members competent by education, training, experience and licensure, to do the industrial surgery required in industrial accident insurance, willing to undertake this work and willing to make prompt and accurate reports of all cases. If a physician claims to be praticing any specialty exclusively, his specialty should be indicated with his experience and qualifications as above mentioned.

It is recommended that the County Societies assume the responsibility not only of providing the state Secretary with this original list but of providing at least a monthly list showing changes in this panel.

No attempt should be made to indicate the manner in which any society shall reach its conclusions, nor is any machinery suggested for determining the result. It must, however, be understood that every society certifying a panel will stand sponsor for the accuracy of the statements given as to the men's education, training and other qualifications to do insurance work, and agrees to demand from them and extend to them the customary professional support and courtesies.

The committee believes that if this course be adopted by the County Societies it will result in better treatment for beneficiaries and a more equitable distribution of industrial medicine practice, and that carriers when assured of these facts will accept the plan.

JAMES H. PARKINSON,
JOHN H. GRAVES,
GAYLE G. MOSELEY.

The report was presented to the council in October and was unanimously adopted. It was subsequently presented to the Industrial Medicine Section of the San Francisco County Medical Society by the full committee and the secretary and the attorney. Later it was laid before the Los Angeles County Medical Association at a special meeting, the full committee and the secretary and the attorney also being present. Prior to this, the subject had been presented to the Sacramento Society for Medical Improvement.

As a result of these gatherings a very general discussion of the question ensued, and in light of the suggestions evolved the report was taken up at the meeting of the council in January and amended so as to make the conditions of certification more specific.

It had now become apparent that the county societies wanted a definite procedure outlined, and this was emphasized in the extensive correspondence that followed. In deference to this general sentiment, questionnaires and form letters were submitted by the secretary and, after conferences with the committee and examination by the attorney, were amended and ordered printed and issued.

The following are the forms as finally approved:

.....M. D.
Secretary.....County Medical Society

Dear Doctor:

After mature deliberation, the State Medical Society's Committee in Industrial Medicine submitted the following report at the meeting of the Council on September 24, 1921, when it was adopted in principle. It was amended and resubmitted at the meeting on January 28, 1922; was unanimously approved and ordered put into effect.

Adoption of Blanks and Fee Schedule—The committee requests that it be authorized to hold conferences with insurance companies and with individual representatives of same, to secure the general adoption of the Society's blanks which automatically adopts the fee schedule.

Increase in Fees—The committee believes conditions at present are inopportune for seeking an increase in the present fee schedule and recommends that action be deferred until prices have stabilized and the business outlook improves.

Enlargement of the Panel—In line with its former suggestions the committee believes steps should at once be taken to enlarge the panel. It recognizes that, while many physicians believe the injured employe should have the right to choose his medical attendant, this right cannot be conceded by those legally responsible for his care and legally liable for every expense attached thereto. At the same time, there is no reason why men competent to do surgical work and to make the necessary reports should not be permitted to treat all cases referred to them by employers.

The question of professional competency is not based upon personal preference, nor can it with certainty be determined by a layman nor, indeed, by an insurance company not employing a medical director. The medical profession is the only judge of the qualifications of its members and their efficency in the various specialties.

The committee, therefore, recommends that various County Societies be requested to assume this responsibility toward the State and that each Society be instructed to certify to the Secretary of the State Society, a list of its members competent by education, training, experience and licensure, to do the industrial surgery required in industrial accident insurance, willing to undertake this work and willing to make prompt and accurate reports of all cases. If a physician calims to be practicing any specialty exclusively, his specialty should be indicated with his experience and qualifications as above mentioned.

It is recommended that the County Societies assume the responsibility not only of providing the State Secretary with this original list but of providing at least a monthly list showing changes in this panel.

No attempt should be made to indicate the manner in which any society shall reach its conclusions, nor is any machinery suggested for determining the result. It must, however, be understood that every society certifying a panel will stand sponsor for the accuracy of the statements given as to the men's education, training and other qualifications to do insurance work, and agrees to demand from them and extend to them the customary professional support and courtesies.

The commitee believes that if this course be adopted by the County Societies it will result in better treatment for beneficiaries and a more equitable distribution of industrial medicine practice, and that carriers when assured of these facts will accept the plan.

JAMES H. PARKINSON,
JOHN H. GRAVES,
GAYLE G. MOSELEY.

This report is submitted to your society with the following suggestions and recommendations:

1. That you endorse the report and instruct your governing body to carry out its provisions.
2. That you have executed the accompanying forms, returning them promptly to this office.
3. That, after the list is completed and in the hands of the State Secretary, you will forward as often as necessary but always in your monthly report any and all changes in your society's panel.

Sincerely yours,

.....
Secretary.

California State Medical Society,

.....County Medical Society, and

.....M. D., member.

Agreement

(If interested in doing Industrial Medicine and Surgery and in being on the panel submitted by the Medical Society, please prepare this form and return it promptly to the Secretary of your County Society.)

I have read the report of the Committee on Industrial Medicine as approved by the Council. I am familiar with the provisions of the Workmen's Compensation

Act and with the rules, regulations and procedures through which it operates.

I understand that all the State Medical Society can do towards securing a wider and more equitable distribution of industrial work is to keep an authorized panel before the carriers. The amount of work secured by members must always be by superior facilities for conducting this business and by individual effort.

I agree to adhere to, follow and abide by the Fee Schedule as adopted May 11, 1920, and any amendments thereto hereafter approved by the Council of the State Medical Society, and the rules and regulations for the administration of the law approved, and any amendments thereto and any additional rules and regulations hereafter approved by the Council of the State Medical Society, including the arbitration and adjustment by any duly authorized committee of the State Medical Society of all controversies that may arise between myself, the carrier, the employer or the injured employe in relation to services performed under the provisions of the Workmen's Compensation Act.

Education, Training and Experience
(Information for Carriers)

Answer by number; use all the space desired.

1. General Education:
Schools and colleges attended; degrees and dates.
2. Professional Education:
Schools, degrees and dates.
3. Intern and Resident Experience:
Names of hospitals and dates.
4. Other Graduate Instruction or Special Work:
Give places and dates.
5. Outline of Experience Since Graduation:
6. Membership in Organizations:
Medical, fraternal, civic and welfare.
7. Present Activities:
Note any special features of work.
8. Industrial Medicine.
Note experience, also present relations and any other matters of interest.
9. Remarks:
Add any information that might be useful to interested carriers.

It will be some time before all the county societies will have reported and a longer period before the results have been tabulated and presented to the carriers. Meanwhile, the committee would again emphasize the fact that this does not mean more business for any member of the society. The committee feels it will result in a wider distribution. It again asserts that the executive officers of the society cannot create business and that as this business, legally, is assigned by one of two authorities—the carrier or the employer—physicians desiring to engage in same must seek it at its source.

The recommendation of the committee that an adjustment bureau should be created and that meanwhile the secretary's office would endeavor to conduct such business as might come to it, met with a prompt and rather unexpected response. Several of the insurance companies assumed that the bureau was already in operation, and this, with an increasing interest on the part of our membership, produced a mass of correspondence and detail work that the regular office force was inadequate to handle.

On December 1, 1921, Miss Virginia Davinroy was employed for the special purpose of dealing with the industrial accident problems, which affect our membership. Under the direction of the secretary, she has been carrying on the correspondence incidental to this work. She was also instructed to confer with the representatives of every insurance company doing compensation business in California to ascertain whether they were using the report blanks and, if not, to secure their adoption. The carriers were informed that the society had established an adjustment bureau and their co-operation with it was solicited.

At this date Miss Davinroy had conferred with thirty-one companies; of these six are using the society's report blanks and thirteen have agreed to use them after their present supplies are exhausted. Six of the local representatives are in favor of the blanks and will take up the matter with their home offices. Six companies expressed themselves as opposed to them, apparently on the ground that their use tended to inhibit cut-rate medical service.

Twenty-six of the companies are willing to co-operate with the society in every way and seem much impressed with the opportunity afforded.

It is hoped that the bureau now established will materially aid in the solution of our problems, while offering definite and practical service to our members. The data that will accumulate during the coming year should indicate our real needs. If these seem to demand a more extended service the committee will be prepared to submit a plan that will afford it.

JAMES H. PARKINSON,
JOHN H. GRAVES.
GAYLE M. MOSELEY.
Committee.

Action by Reference Committee—The committee recommends that the Committee on Industrial Medicine be continued and that the council, if it deems advisable, be authorized to extend the functions of said committee, and to establish an Industrial Service Department for the better regulation and control of the practice of industrial medicine and surgery, the relations of members engaged in such practice with insurance carriers and all re-

lated matters, said department ultimately to be placed upon a self-supporting basis.

Action by House of Delegates—Upon motion duly made and seconded, it was unanimously resolved that the recommendation of the committee be adopted as read and the action of the Committee on Industrial Accident Insurance be sustained.

2a. **Resolution No. 1—Rate-Cutting in Industrial Accident Insurance Work**—The text of the resolution is as follows:

Whereas, It is generally known to the medical profession of California that certain members of the medical profession and of the Medical Society of the State of California wilfully accept fees lower than schedule for services under the Workingmen's Compensation law and in various other ways circumvent the intent of the fee schedule adopted by the Medical Society of the State of California and the Industrial Accident Commission of California, and

Whereas, It is generally known to the medical profession of California that certain members of the medical profession and the Medical Society of the State of California wilfully and for the purpose of securing business, underbid their colleagues, thereby depriving them of business which they have secured, and by devious and unethical methods work harm in other ways to their confreres, and

Whereas, Such practices, if continued and extended, as will probably be the history in the Industrial Accident work, if not regulated, will work vast harm to the cause of medicine and the cause of medical science, therefore, be it

Resolved, That the Industrial Medicine and Surgery Section of the Medical Society of the State of California request the Society to, through its regular channels, investigate these conditions and practices and take action, if action is deemed proper, to secure relief, and

Resolved, That the Industrial Medicine and Surgery Section of the Medical Society of the State of California offer any information, testimony and assistance in its power to further this investigation and relief, and

Resolved, That it be the ruling of the House of Delegates that any violation of the fee schedule by any member, directly or indirectly, or any connivance thereat constitutes unethical conduct on the part of such member.

Action by the Reference Committee—The committee recommends the adoption of the resolution.

Action by the House of Delegates—Upon motion duly made and seconded it was unanimously resolved that the recommendation of the Reference committee be approved.

3. **Resolution No. 2—California Association of Radiographers**—The text of the resolution is as follows:

Resolved, That the Council (as members of the Advisory Council of the California Association of Radiographers) be instructed to vote in that body to amend the preamble thereof in accordance with the amendment thereof in the hands of the Publicity Bureau, and if same is not accepted by said association of radiographers, that the Council be instructed to sever all connections thereof, and for that purpose to bring about a meeting of the Advisory Council at as early a date as possible.

Action by Reference Committee—The committee recommends that in place of the resolution submitted to the House of Delegates at its meeting on Monday, May 15, 1922, the following preambles and resolutions be adopted as the sense of the society:

Whereas, The House of Delegates at the meeting held in Coronado in May, 1921, empowered the Council to organize associations of technical specialties, and

Whereas, The California Association of Radiographers was organized with a preamble and constitution which permits technicians to diagnose and to treat disease by means of the roentgen ray or radium upon the prescription of physicians, surgeons or dentists, and

Whereas, The section on radiology approves the formation of an association of technicians to be known as the Association of Radiographers, the membership to be limited to technicians who are working under the direct supervision of members of the State Medical Society;

Resolved, That it be the judgment of the Medical Society of the State of California that the diagnosis of disease and its treatment by X-Ray or radium therapy and the interpretation of plates of pathological conditions is the sole province of the medical profession;

Resolved, That X-Ray or radium treatment by lay technicians should never be administered except under the immediate supervision of a legally qualified practitioner;

Resolved, That members of the Association of Radiographers may only operate in laboratories under the direct supervision of a member of this Society;

Resolved, That the foregoing shall be deemed the interpretation of this Society of matters of policy affecting the educational and ethical activities of the members of the State Association of Radiographers, and that it is the sense of the Society that the preamble and constitution of the California Association of Radiographers be so amended as to give these resolutions effect; and that the Council of the Society be, and it is hereby instructed to carry out the necessary details in making them effective;

Resolved, That insofar as the radiographers and the dental members of the Association are concerned, the adjustment of this relationship be left to accredited members of the dental profession.

Action by the House of Delegates—Upon motion duly made and seconded it was unanimously resolved that the recommendation of the Reference Committee be approved.

4. **Resolution No. 3—Uniformity in Medical Fees**—The text of the resolution is as follows:

Because of the lack of uniformity in the matter of fees charged for medical services throughout the state, and because of the advantages of more uniformity, therefore, in accordinace with the suggestions of the State Secretary be it

Resolved, That a "committee on an ideal fee schedule" be appointed from members of the State Society, to study the whole question of fees, and prepare a report to be submitted to each county during the next year; this committee to report back to this body at the next annual meeting.

Action by the Reference Committee—The committee recommends that a committee of nine be appointed by the president to consider the whole question of medical fees and to report at the next annual meeting.

Action by the House of Delegates—Upon motion duly made and seconded it was unanimously resolved that the recommendation of the Reference Committee be approved.

5. **Resolution No. 4—Director of State Institutions**—The text of the resolution is as follows:

Whereas, The State hospitals for the insane and the Sonoma State Home for Feeble-Minded comprise the medical division of the State's service, and

Whereas, We feel that the care and supervision of these institutions should be under the direction of a medical man, and

Whereas, Dr. John A. Reily, former medical superintendent of the Patton State Hospital, has been appointed to the position of Director of State Institutions, and

Whereas, On account of Dr. Reily's long and efficient service in the care and management of the insane, we are confident that the department of the state's service under his jurisdiction will be conducted in an efficient and economical manner, be it

Resolved, That the San Joaquin County Medical Society at this meeting on May 12 commend Hon. William D. Stephens, Governor of the State of California, for appointing Dr. Reily, and be it further

Resolved, That a copy of these resolutions be forwarded to Governor Stephens.

Action by the Reference Committee—The committee recommends the approval of the resolution of the San Joaquin County Medical Society commending Governor Stephens for his action in appointing a medical man as superintendent of State Medical Institutions.

Action by the House of Delegates—Upon motion duly made and seconded it was unanimously resolved that the recommendation of the Reference Committee be approved.

6. **Resolution No. 5—Exceptions to State License Requirements**—The text of the resolution is as follows:

Resolved, That the Council of the State Society be authorized to make exception to the existing state license requirements for active membership in local and state societies in specific instances and under such conditions as seem to them sufficient.

Action by the Reference Committee—The committee recommends the approval of the resolution of the Council that it be authorized to make exceptions to existing state license requirements for active membership in local societies in specific instances and under such conditions as seem sufficient.

Action by the House of Delegates—Upon motion duly made and seconded it was unanimously

resolved that the recommendation of the Reference Committee be approved.

7. **Resolution No. 6—Instruction of Delegates to A. M. A.**—The text of the resolution is as follows:

Resolved, That it is the policy of the Society to instruct by resolution, either of the House of Delegates or of the Council, the delegates of this society to the American Medical Association, on all matters of national concern upon which this society either has or desires to institute a definite policy, or which, in the opinion either of the Council or of the House of Delegates peculiarly affects this society.

Action by the Reference Committee—The committee recommends approval of the resolution of the council that delegates to the A. M. A. be instructed on matters of national concern on which the society desires a definite policy.

Action by the House of Delegates—Upon motion duly made and seconded it was unanimously resolved that the recommendation of the Reference Committee be approved.

8. **Resolution No. 7—A. M. A. Meeting for 1923**—The text of the resolution is as follows:

Resolved, That delegates to the A. M. A. be instructed to use every effort to bring the A. M. A. to San Francisco for 1923.

Action by the Reference Committee—The committee recommends approval of the resolution of the council that delegates to the A. M. A. be instructed to use every effort to bring the association to San Francisco in 1923.

Action by the House of Delegates—Upon motion duly made and seconded it was unanimously resolved that the recommendation of the Reference Committee be approved.

9. **Resolution No. 8—Better Health Service**—The text of the resolution is as follows:

Whereas, the Better Health Service, conducted and edited for the San Francisco Examiner by the League for the Conservation of Public Health is presenting the important facts of modern preventive and curative medicine in practical and popular form, be it

Resolved, That the Medical Society of the State of California, assembled in its fifty-first annual convention, commend this worthy enterprise that is destined to conserve, protect and improve the public health.

Action by the Reference Committee—The committee recommends adoption of the resolution of the council commending the "Better Health Service" now being conducted in the public press.

Action by the House of Delegates—Upon motion duly made and seconded it was unanimously resolved that the recommendation of the Reference Committee be approved.

10. **Resolution No. 9—Health Centers**—The text of the resolution is as follows:

Whereas, It always has been and is the primary purpose of physicians to give trained, scientific, sympathetic service to all of their fellow citizens who need medical advice and to furnish this service to all alike, regardless of the social or financial standing of the patient, and

Whereas, It never has been and is not now necessary to interpose any agency not under the direct supervision and control of competent members of the medical profession, members are reminded of the dangers of co-operation in agencies where such supervision and control does not exist, and

Whereas, In order to re-emphasize these policies and practices to all citizens of California, and to counteract the influences going about the state to the effect that consideration by physicians for those needing medical advice can be obtained only by applying to some non-medical organization, and in order that the public may be fully informed and free to call directly upon the physician of its choice with the assurance of sympathetic and confidential consideration, therefore, be it

Resolved, By the Medical Society of the State of California and representatives of all county and other constituent organizations, in convention assembled, that the office of each of its 4000 members throughout the state is a "Health Center" of the kind that means the best medicine and public health advice that physicians can give; this upon the basis that those who can pay in full should do so, those who can pay part should do so, and those who are unable to pay should have the service without cost.

Resolved, That in order to secure special financial consideration, the patient is requested to execute and sign a paper showing his socio-financial status and setting forth briefly the reasons why he must ask for special financial consideration, this being the policy now being followed by clinics and welfare organizations of all sorts.

(Note:—The State Society will supply each of its members with appropriate blank forms for this purpose, and will furnish one to any citizen who desires to use it. One of these forms presented to any member of the State Society in any part of the state will insure the courtesies and special consideration that his condition warrants and, in addition, he will receive the same sympathetic, confidential, constructive help that is given to the person who is able to pay fully for all that he requires. In carrying out this program, physicians reserve the right, when they think wise, to check up on the accuracy of the applicant's statements in an unobtrusive and sympathetic manner, in exactly the same way as those reports are now being checked up by clinics and other welfare organization. Members also reserve the right to refer applicants for special consideration to other physicians under the same conditions and for the same reasons that they would refer patients paying regular fees. Any sick person in any part of the State of California who fails, for any reason, to secure adequate medical attention is requested to communicate with the Secretary of the State Medical Society, 929 Butler Building, San Francisco.)

Action by the Reference Committee—The committee recommends the adoption of the preamble and resolutions on "Health Centers," as introduced by the Council and submitted by a special committee consisting of Doctors Kress, Paterson, and Edwards.

Action by the House of Delegates—Upon motion, duly made and seconded, it was unanimously resolved that the recommendation of the Reference Committee be approved.

11. **Resolution No. 10. Extension of Better Health Service**—The text of the resolution is as follows:

Resolved, That the Publicity Bureau be instructed to present to the League for the Conservation of Public Health the desire of this Society to have it extend its "Better Health Service" as now conducted as rapidly as possible.

Action by the Reference Committee—The committee recommends that the Publicity Bureau be instructed to present to the League for the Conservation of Public Health the desire of this Society to extend this service.

Action by the House of Delegates—Upon motion, duly made and seconded, it was unanimously resolved that the recommendation of the Reference Committee be approved.

12. **Resolution No. 11. Annual Dues**—The text of the resolution is as follows:

Resolved, That the annual dues for the year 1923 be fixed at $10, and that a special committee be appointed to prepare a statement embodying the discussions of the Council on the question of dues in relation to medical and indemnity defense to submit to the House of Delegates.

Action by the Reference Committee—The committee recommends that the dues for the year 1923 be fixed at $10.

Action by the House of Delegates—After hearing the report of the special committee mentioned above, consisting of Doctors Bine, Pope, and Paterson, and a statement by Dr. Harlan Shoemaker, secretary of the Los Angeles County Medical Society, and Dr. W. W. Beckett of Los Angeles, upon motion duly made and seconded, it was unanimously resolved that the recommendation of the Reference Committee be approved.

13. **Resolution No. 12—Provision for Segregating Expenses and Method of Providing Medical Defense**—The text of the resolution is as follows:

Whereas, the secretary has explained that the increase in the dues this year depends upon three factors: extension work, industrial accident insurance adjustment bureau, and medical defense, and

Whereas, of these items that of medical defense is by far the largest; therefore, be it

Resolved, That the House of Delegates instruct the Council to present at the next annual meeting a plan by which the legal defense will be limited to those members who desire to receive and to pay for same as a separate charge; and that the assessment for medical defense be segregated from the general dues, so

that the dues may not be subjected to a possible advance for that purpose.

Action by the Reference Committee—The committee recommends that the resolution be adopted.

Action by the House of Delegates—Upon motion, duly made and seconded, it was unanimously resolved that the recommendation of the Reference Committee be approved.

14. **Resolution No. 13—Indemnity Defense Fund Assessment**—The text of the resolution is as follows:

Resolved, That an assessment of $10 be levied on the members of the Indemnity Defense Fund as of January 1, 1922, due and payable on or before August 1, 1922, and delinquent November 30, 1922.

Action by the Reference Committee—The committee recommends the approval of the resolution of the Council that an assessment of $10 be levied on members of the Indemnity Defense Fund as of January 1, 1922, due and payable on or before August 1, 1922, and delinquent November 30, 1922.

Action by the House of Delegates—Upon motion, duly made and seconded, it was unanimously resolved that the recommendation of the Reference Committee be approved.

15. **Report of the Committee on Codification of Constitution and By-Laws:**

Action by the Reference Committee—The committee recommends, in accordance with constitutional provision, that the proposed revised constitution and by-laws be published in the Journal twice during the year, and submitted for action at the meeting of 1923.

Action by the House of Delegates—Upon motion, duly made and seconded, it was unanimously resolved that the recommendation of the committee be approved.

Resolution of Appreciation—The following resolution was unanimously passed by the House of Delegates, and the secretary was instructed to send a copy to each of the officers concerned:

Resolved, That the House of Delegates of the Medical Society of the State of California wishes to make of record its very great appreciation of the earnest, sympathetic, effective efforts of the officers of the Yosemite Transportation Company and the officers of Camp Curry, in making the 1922 meeting of the Society so wonderfully successful, attractive and interesting;

Resolved, That the meeting adjourns with the unanimous feeling that everything possible has been done for our comfort and the success of our meeting; and a vote of thanks is extended to the Yosemite Lodge and its officers,, particularly Mr. H. H. Hunkins and Mr. R. E. McCormick; to Camp Curry, particularly Mrs. Curry and her assistants, for their splendid co-operation in making the convention so successful;

Resolved, That the Society also desires to express its appreciation to the Yosemite National Park Rangers for their unfailing courtesy, sympathy and assistance in helping to make the convention so successful.

Presentation of the President—Henry G. Brainerd of Los Angeles, the incoming president, was escorted to the chair by Doctors Bine and Yates. Dr. Brainerd presented his inaugural address to the general sessions, and it is published on page 215 of this number of the Journal.

Presentation of the President-Elect—Thomas Clay Edwards of Salinas, President-Elect, was escorted to the platform by Doctors Pope and McArthur, and expressed his appreciation of the honor conferred upon him.

Adoption of Minutes—The minutes of the first and second sessions were read and duly adopted.

Adjournment—There being no further business before the House, the meeting adjourned to meet in San Francisco at a time to be fixed by the Council.

REPORT OF THE DELEGATES OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA TO THE AMERICAN MEDICAL ASSOCIATION MEETING IN ST. LOUIS

The American Medical Association has held another successful annual meeting. St. Louis did well, entertaining five thousand medical men. This is no small task, and some crowding of hotels must be expected. There was little complaint, however, on this score, though the distance from meeting places, together with the scattered location of these was frequently deplored.

There was again evidence of the numerous special societies into which the medical profession is organizing itself. Many cluster about the larger meeting of the American Medical Association with its numerous sections, but are not a part of that organization. A living illustration of the enthusiasm for progress in the conquest of disease and the limitation of the lines of individual endeavor that each field may be the more deeply cultivated.

Aglow with possibilities stands the great inclusive organization of the A. M. A. with its eighty-nine thousand members, the greatest power for the relief of human suffering in all this world. Is there any excuse for this great body not acting as a unit? Really, there was less friction and rubbing of factions than at any previous meeting which I know of. Best of all it was more than ever evident that all were working together for the common good of the profession, and through it the greatest good to mankind.

One of the impressive actions of the House of Delegates was the endorsing of the plan to distribute blanks for the recording of physical examinations and re-examinations of our well patients.

Imagine the benefits resulting from systematic annual or semi-annual examination of all men, women and children in the United States.

The outstanding activity to us Californians was, of course, the always-important election of the president-elect and the selection of the next place of meeting. That we were able to secure both for California is ground for great satisfaction to your delegates. All stood together nobly, and many representative Californians, though not delegates, did yeoman service for our program. We are proud of Dr. Wilbur. We are certain that no mistake was made in his election. His grasp of the problems of medical education was no small factor in his selection for this honored position, and we trust there will be no disappointment in the hope that he will be able to unite the many varying plans for the much-needed revision of our medical curriculum.

More than all it was a pleasure and cause for rejoicing that California numbers so many staunch friends among the outstanding men of the profession in all parts of the United States. May we be able to live up to our opportunities, and may we stand together for the heartiest reception ever accorded the American men of medicine. The Association is worthy of all we can give it. It is no small task for the State, and a great undertaking for San Francisco to entertain the A. M. A. next June, which should have the whole-hearted support of the profession of the entire State.

Most of all, let us show our appreciation by attending in mass, that the full benefit may accrue to our entire membership.

C. VAN ZWALENBURG.
ALBERT SOILAND.
VICTOR G. VECKI.
E. C. FLEISCHNER.

COUNTY NEWS

ALAMEDA COUNTY

Alameda County Medical Society (reported by Charles L. McVey, secretary)—The May meeting was held at the Public Health Center in Oakland. The program was prepared by A. M. Meads from the members of the staff of the Alameda County Hospital. Charles Miller discussed the history of the County Hospital, emphasizing particularly the advance that had been made in the type of medical and surgical work being rendered the patients. A. H. Rowe demonstrated lantern slides illustrating several phases of Hypo- and Hyper-thyroidism. S. A. Jelte, T. J. Clark, A. Cary, F. Fontaine, and F. L. Loomis talked on the choice of minor procedures in obstetrics. Frank S. Baxter read a paper on Accessory Sinus Disease in Children. Q. O. Gilbert read a paper on Some Aspects of Intravenous Therapy in Severe Infections.

FRESNO COUNTY

Fresno County Medical Society (reported by T. F. Madden, secretary)—At the meeting on May 2 the society was the guest of the Burnett Sanitarium at a dinner at the Hughes Hotel. There were also present a delegation of twenty-one members of the Alameda County Society.

S. K. Jamgotchian, W. B. Milholland, and A. T. Goldberg of Fresno were elected to membership.

The program was furnished by the staff of the Merritt Hospital of Oakland. George Rothganger, M. D., acted as chairman, and the following papers were presented:

"Some Neglected Landmarks in Therapeutics," by H. N. Rowell; discussion by Dr. Schottstaedt of Fresno, and Dr. Alexander of Oakland.

"The Surgical Abdomen," by S. H. Buteau; discussed by Dr. Morgan and Dr. Cross of Fresno.

"X-ray Therapy," by A. C. Siefert; discussion by Dr. Milholland of Fresno.

"Spinal Anesthesia," by M. L. Emerson; discussants, Doctors Vanderburgh, Buteau, Rothganger, and Dixon.

RIVERSIDE COUNTY

Riverside County Medical Society (reported by T. A. Card, secretary)—The meeting of May 9 was held in the Chamber of Commerce rooms, with thirty members and ten guests present. Silas J. Brimhall of Elsinore, and Florilla M. White of Palm Springs were elected to membership.

The scientific program consisted of the following: Notes on the Management of Infants, Victor E. Stork, M. D., of Los Angeles; Dermatology and the General Practitioner, by Moses Scholtz of Los Angeles. Dr. Stork's paper dealt largely with the breast-fed infant, stressing the importance of breast nursing as a factor in reducing infant mortality. He also discussed the diet of the sixth to twelfth-month infant. Dr. Scholtz discussed the diagnosis and treatment of some of the common skin lesions.

A number of dogs and cattle have died of rabies in Riverside County recently, and the State Board of Health has quarantined against this infection.

SAN DIEGO COUNTY

San Diego County Medical Society (reported by Robert Pollock, M. D.)—On account of meetings of the National Society and our own State Medical Society during May, the only meeting of the San Diego Society was held May 9, when a discussion of the therapy of goitre was enjoyed. This was opened by papers by Thomas O. Burger and Lyell C. Kinney on the surgical and radiologic treatment, respectively. A liberal discussion followed.

John D. Hartley and Martha Welpton represented the San Diego Medical Society at the A. M. A. meeting in St. Louis. Martha Welpton, M. D,. was elected vice-president, and Marjory Potter, M. D., secretary of the Medical Women's National Association at its recent meeting at St. Louis. On May 18, O. G. Wicherski, county physician, delivered diplomas to the graduating class of the nurses' training school at the San Diego County General Hospital. The following members of the county society attended the Yosemite meeting of the State Society: H. A. Barclay, Charles W. Brown, F. A. Burton, J. D. Hartley, L. C. Kinney, T. Coe Little, E. Blanche Ramer, C. E. Rees, R. G. Sharp, and John Yates.

SAN FRANCISCO COUNTY

San Francisco County Medical Society (reported by Le Roy H. Briggs, secretary)—The Committee on Medicine met on May 2. The two papers presented were "A Plan of Intensive Treatment for Congenital Syphilis" by Hermann Schussler, and "Treatment of Acquired and Active Syphilis," by H. E. Alderson and G. H. Becker.

Medical Officers Organize—The San Francisco medical sector of the Association of the Army of the United States, authorized under the Act of June, 1921, has been perfected.

The Association, under the leadership of General Thornwell Mullally, has been in active operation for some months, and has been holding bi-weekly luncheons, at which lectures on important army topics have been given by experts.

To Colonel Bannister was assigned the task of organizing the medical sector of this army unit. By-Laws were adopted, and the following officers were assigned:

Col. W. B. Bannister, Surgeon of the Ninth Corps Area, chairman; Dr. Philip King Brown, vice-chairman; Dr. R. J. Dowdell, second vice-chairman; Major M. H. Eppstein, secretary; Dr. E. H. Angermann, treasurer.

Dr. J. Wilson Shiels, Dr. Morton H. Gibbons, Major J. M. Downs, Acting Division Surgeon of the Ninety-first Division, were appointed a Committee of Arrangements.

About sixty members of the old Ninety-first Division were enrolled as members.

California Academy of Medicine—The next meeting of the California Academy of Medicine will be held July 8, at a dinner at the Fairmont Hotel. The guest of the evening is to be Dr. Ernest Fuchs of Vienna. Dr. Fuchs is famous for his special work on the eye. He will address the Society on the subject of "The Eye and the Endocrines."

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by A. C. Soper, secretary)—The May meeting was held at the Cottage Hospital. Horace F. Pierce presented a case of Cretinism, and discussed the subject. "The Present and Future of Thoracic Surgery" was the subject of a paper by Samuel Robinson, which was discussed by C. S. Stevens, G. L. Chaffin, and H. J. Ullmann.

At the meeting of May 8, G. F. Farman read a paper on "Prostatic Massage." Mellinger's paper was on "Diphtheria of the Middle Ear," with special reference to virulent and non-virulent types of diphtheria bacilli.

The Society is engaged in an effort to establish a milk committee for the certification of milk in Santa Barbara County.

SANTA CLARA COUNTY

Santa Clara County Medical Society (reported by E. P. Cook, secretary)—The May meeting of the society was held in the society rooms in the Twohy building, San Jose. The meeting was in charge of Frank H. Paterson, councilor from the fifth district of the State society. Reports from the State convention were given by F. H. Paterson, C. M. Richards, M. W. Kapp, J. H. Shephard, and G. L. Barry.

W. Lester Wilson was accepted to membership by transfer from the Stanislaus County Medical Society.

New Home for the Stanford School of Nursing—The trustees of Stanford University opened the new nurses' home on the 31st of March, with formal exercises in the afternoon and a dance in the evening. The presentation of the home to the university was made by William Mayo Newhall, president of the board of trustees, and accepted by Ray Lyman Wilbur, president of Stanford University.

SONOMA COUNTY

Sonoma County Medical Society (reported by N. Juell, secretary)—The June meeting of the Society was held at Santa Rosa on the 8th, with ten members and two visitors present, and twenty-five members absent. Max Rothschild spoke on tuberculosis with special reference to modern treatment. J. H. McLeod and C. N. Mooney reported to the Society on the activities of the annual meeting of the California State Society at Yosemite.

The Society took necessary steps to secure the data provided for by resolution of the House of Delegates in order to increase the panel of our own members to practice industrial medicine.

STANISLAUS COUNTY

Stanislaus County Medical Society (reported by R. E. Maxwell, secretary)—The meeting of May 12 was held at a local hotel with President Fields in the chair. Members present were Mottram, Benson, Surryhne, Finney, Sturgis, Morgan, Bemis, McPheeters, Fields, Young, Reamer, De Lappe, McKibbon, and Maxwell.

Dr. Lester Wilson was given a transfer to the Santa Clara County Society. A. E. Julien of Turlock was elected to membership.

Dr. F. R. De Lappe, as chairman of the fee schedule committee, submitted a tentative report. A resolution was passed instructing the delegate to the State society to bring before the House of Delegates a recommendation that they appoint a State committee for consideration of a uniform fee schedule.

A paper by Dr. Polak upon "Abuse of Caesarian Section" was read by Dr. Surryhne.

New Associate Secretary—Following out the policies endorsed by the Council, the Publicity Bureau has appointed Dr. Howard H. Johnson full-time associate secretary of the State Medical Society.

Dr. Johnson's academic degree is from Miami, and his medical degree from the University of Cincinnati. His intern service was in the Cincinnati General Hospital, and he has since that time had a large and important experience, both in military and civil life, in medical administrative work. The co-operation of members of the State Society in making his services useful to the public and the physicians is requested.

EXTENSION WORK

The following additions have been made to the Extension Lecture courses offered by members of the State Society to local societies: (See November, February and March Journals for other lectures.)

A. GOTTLIEB, M. D.,
603 Consolidated Realty Building, Los Angeles.

1. **Physiotherapy in Orthopedic Practice:**
   The usefulness and mode of application of the various physical modalities in deformities acquired after accidents. Statistics and lantern slides.

2. **The Painful Foot:**
   A discussion of the possible painful foot conditions of local and remote origin. Prevention and treatment.

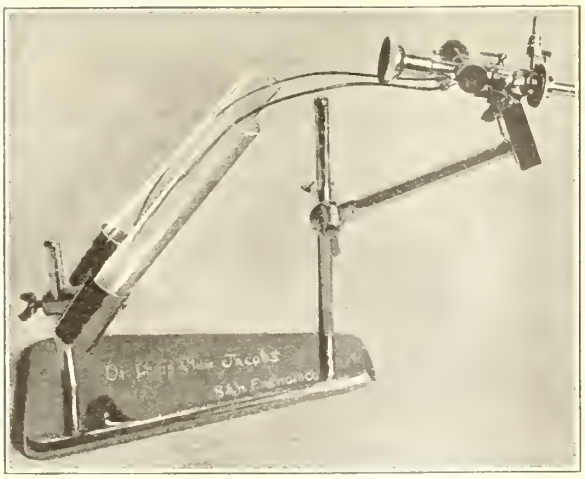
3. **Backsprains and Their Treatment by Physical Therapy:**
   Diagnosis of sprains by elimination and early treatment with physical and mechanical modalities in acute conditions. Physio-therapy of chronic backsprains.

4. **Metatarsalgia:**
   Etiologic factors, with special reference to the high-heeled shoe, which cause contracture of the "tendon Achilles" and leads to metatarsalgia. Prophylaxis and treatment. Lantern slide demonstrations.

5. **Orthopedic Principles in the Early Treatment of Injuries:**
   A discussion of immobolization vs. mobilization and preventive physiotherapy. Statistics and lantern slides.

Upheld by the Highest Court—The laws of Ohio relating to the practice of medicine and surgery require that all who engage in the treatment of the sick in that State, including chiropractors, shall first submit to examination by the State Medical Board in certain fundamental branches. The constitutionality of these laws has now been passed on by the Ohio Court of Appeals, the Ohio Supreme Court, and the United States Supreme Court, the last named having refused to review the decision of the Supreme Court of Ohio which, in an unanimous opinion, declared the laws constitutional and approved the rules and regulations of the State Medical Board. Thus the great principle for which the medical profession of this country has contended has been approved and upheld by the Appellate Court and the Supreme Court of one of our greatest States and, finally, by the Supreme Court of the United States. The opinion of the Supreme Court was handed down by Chief Justice Taft.

With characteristic effrontery, as is stated in current accounts of the situation, a rather large group of the chiropractors of Ohio announced, at a meeting in Akron, that they would "go to jail" before they would obey the law, even though that law has been upheld by the highest court of the land. Of course, the next move of these law violators and law defiers will be to get a little law of their own, if they can, at the hands of the next Legislature in Ohio. It is to be hoped that the members of that Legislature will be so informed that they will be convinced of the righteousness of the principle for which the medical profession contends, and it is to be hoped, too, that the public will be so informed as to their own interests in the matter as to demand from the Legislature that the chiropractor shall be no less well qualified in fundamental subjects than any other who is to be allowed to treat the sick. (American Medical Association Bulletin, April 15, 1922.)



A SIMPLE APPARATUS FOR HOLDING CYSTOSCOPE AND COLLECTING TUBES

There has always been a long-felt want for an apparatus that would aid the urologist in the collection of urine from the kidneys following cystoscopy. In the performance of various functional tests and certain X-ray procedures, there were difficulties encountered by many urologists who did not have access to some form of contrivance or apparatus that would hold the receptacles and cystoscope during the collection of urine following ureteral catheterization.

In recent years there have been placed upon the market various types of holders, which depend upon the principle of being clamped to the examining table, and then to the cystoscope. Most of them have been discarded as impracticable. The most commonly used table for cystoscopic work is the table with the end-leaf, which leaf can be lowered or placed at a horizontal plane parallel with the remainder of the table, enabling the patient to stretch out the limbs at full length; which position is usually employed in transferring a patient to the radiographic department for pyelograms.

For this reason I devised the following apparatus: There is a short metal base, from the anterior part of which is a perpendicular rod, attached to which is a horseshoe-shaped bar with two depressions, which tilt at various angles. This supports the cystoscope. The latter, swinging on this stand, has a ball and socket movement. At the posterior part of the apparatus there is another perpendicular rod, which holds two adjustable shelves for different size test-tubes. The attachments are all interchangeable, making it possible to sterilize the instrument or carry it in a compact mass, and to adjust the holder to any cystoscope and to any size collecting vessel.

After cystoscopy, it is customary to raise the lower leaf of the table, adjusting the apparatus thereon. When the apparatus is in this position, the weight of the cystoscope is evenly balanced, and aids in the comfort of the patient. This position permits the patient extreme laxity of movement, such as might take place in sneezing, coughing, or other respiratory movements.

LOUIS CLIVE JACOBS.

BOOK REVIEW

Lessons on Tuberculosis and Consumption for the Household. Showing how to prevent tuberculosis, how to recognize its first symptoms, how to win back health. By Charles E. Atkinson, M. D. Illustrated. N. Y., Funk & Wagnalls Company. 1922.

It is hard to cover just the ground that would satisfy everyone in a book intended for the laity. Many of them want information on points of no importance, and others with peculiar prejudices wonder that their pet ideas are not given more attention. On the whole, this book has sailed a safe and sane course on the general principles, and will serve as a reference book in answering, by some description, most of the questions that may be asked about method. The Scotch verdict "Not proven" ought to be used a little more freely in reference to a great many methods of treatment, particularly regarding immunization and the value of vaccines.

Questions involved in the influence of climate are so largely matters of opinion, and are of so little importance as compared to opportunities for rest with good food and peace of mind, that all these secondary elements ought to be considered in a purely comparative way. It is easier to live out of doors in a warm place than a cold one, and it is pleasanter to live where it is reasonably dry. Where people can afford the luxury of so-called ideal climates it is all well and good, but the less said about it to the great mass of people the better. It seemed also that the discussion on sun baths is open to criticism, and that the prevailing opinion is that they had better be confined to surgical cases.

DEATHS

Parker, John. Died in Salinas, May, 1922. Was a graduate of Medical College of the Pacific, 1874. Licensed in California, 1876.

Hutchins, Frederick. Died May 4, 1922. Was a graduate of Dartmouth Medical College, N. H., 1870. Licensed in California, 1883.

Hart, Lasher. Died in Los Angeles, May 30, 1922. Was a graduate of Syracuse University, New York, 1903. Licensed in California, 1910, and a member of the Medical Society, State of California.

Sterilization Law Held Illegal—The Supreme Court of Indiana has declared invalid the law-making provision for the sterilization by vasectomy of criminals, idiots, rapists, and imbeciles, whose mental and physical condition would make procreation inadvisable. It is particularly refreshing to note that the court did not rule upon the various controversial points connected with the practice of vasectomy, but based the decision upon the broad grounds of the Fourteenth Amendment to our Constitution.

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.

NON-DYSENTERIC AMEBIASIS *

By ALFRED C. REED, M. D., San Francisco.

The term "amebiasis" was coined in 1904 by Musgrave and Clegg in Manila to describe a "state of infection with amebas," and we are extremely fortunate here today in having with us in person one of the originators of this term, Dr. Musgrave, who has had the rare privilege of observing the development in this country and abroad of work stimulated and begun by himself twenty years ago. Man is subject to infection by at least five varieties of ameba. Of these we are convinced of pathogenicity in the case of one only—Entamœba histolytica. Kofoid and his colleagues have described as Councilmania lafleuri, a species of ameba which they believe to be pathogenic and to have been confused formerly with Entamœba coli. At present this species is under judgment, and its establishment as a new species is open to serious question, so that we can speak with unanimous authority of only one ameba, E. histolytica, whose pathogenic properties have been clearly demonstrated. This species alone, therefore, enters into the present discussion.

Amebiasis is widespread in the human race, some authorities estimating that as high as 10 per cent of the population of the globe is infected. An examination of 2300 overseas men and 576 home service men by Kofoid and Swezy led these workers to conclude that carriers of ameba in the United States were greatly increased by the return of the soldiers, and that carriers are more numerous than was expected among the normal population. Giffin, as early as 1913, in 1700 persons examined in the Middle Northwest, found 148 infected with E. coli, and 79 with E. histolytica.

In California there is evidence of a surprisingly high incidence, as indicated by numerous case reports and surveys. The sources of the endemic distribution in California are chiefly these:

1. Immigration from the Orient, especially of Filipinos, Chinese, Japanese, and East Indians.
2. Immigration and transient labor from Mexico.
3. Tourist travel from California to Asia.
4. The army demobilization.
5. Trade routes centering in California ports.

As in the case of other typically tropical diseases, so here, we have in California special problems and special dangers which require immediate attention.

While until recently considered predominantly a tropical affection, amebiasis is now known to be cosmopolitan and to invade practically every country of temperate climate as well as the tropics. There seems, however, to be a clinical difference in that dysentery is by far a more striking feature in the tropics than in higher latitudes. The common use of the term, tropical dysentery, as a synonym for amebic dysentery, is an illustration of this. It is important to keep clearly in mind that dysentery is merely a syndrome and not a specific disease. By dysentery we mean frequent bowel movements, containing blood and mucus and associated with pain and tenesmus. Dysentery is due to a large variety of causes of which ameba is only one.

An understanding of amebiasis from the clinical point of view requires an exact knowledge of its pathology and of the life cycle of the ameba. Under no circumstances are motile amebas in the dejecta infective for human beings. Their viability is too feeble and they probably never survive passage through the human stomach even if they get this far. Infection of man occurs solely through the agency of cysts. The vectors concerned in this transmission are chiefly water and flies. The cysts ingested by flies are found fully potent in their feces. Dependence on cyst-transference explains why amebiasis is invariably endemic and never epidemic in its incidence.

The cysts are ingested with food or drink by man and pass unchanged through the stomach. In the small intestine the cyst wall is dissolved and probably a single small quadri-nucleate ameba is released. This soon subdivides into four new

* From the Department of Medicine, Stanford University Medical School.

amebas which are carried by the intestinal flow to the colon.

Many authors have described invasion of the small intestine, but almost invariably the colon alone is attacked and the sites of election are the flexures, cecum and rectum. Dobell describes one method of invasion. In this the amebas are seen to congregate in large numbers on the surface of the healthy mucous membrane and gradually erode it by the secretion of a cytolytic ferment which dissolves the epithelial cells. The amebas soon lie in a pool of liquefied epithelium. Dobell states that they do not dislodge the epithelial cells mechanically or burrow between them. They do, however, according to this author, frequently invade the tissue through the crypts of Lieberkuhn. This is a stage of superficial erosion only and while the adjecent capillaries are dilated there is no true tissue reaction.

This erosion may develop into the characteristic type of amebic ulceration. The cytolytic action of the ameba here seen, gives the occasion for the name histolytica and is the one and only definite indication of the production by the ameba of an exotoxin. The ameba lives in direct contact with healthy tissues and not in the necrotic mass resulting from its activities.

Dobell describes the histologic picture as follows:

There first occurs a histolysis of the tissues in direct contact with the ameba and then a dilatation of the nearby capillaries with succeeding thrombosis and round-cell infiltration. Finally a necrosis of varying extent takes place. The typical amebic ulcer gives the appearance of a purely local lesion, with very little if any tissue reaction. The body tissues tend to regenerate whenever and wherever the amebas cease their activity or are removed by specific treatment. Some scar tissue is formed as well as new replacement tissues. The amebas are present in the lesions in vast numbers, in a large motile form. It is probably here that reproduction takes place by simple fission. A certain number of these large amebas, the ones destined for race propagation in a new host, leave the tissues and pass into the lumen of the colon where they are reduced in size and extrude all foreign material and food masses. Then as small, round, clear and very sluggish forms, they proceed to encyst by merely secreting a transparent thin coating. These cysts are carried out by the intestinal contents and their single nuclei subdivide twice, giving an ordinary maximum of four nuclei in the cysts seen in the stools.

Cyst production is not a constant activity of an ameba colony. It does not accur in amebic abscesses as in the liver or brain. Nor does it occur with any regularity in intestinal lesions. The biologic reasons for this are obscure but doubtless have to do with the lack of drainage of necrotic material, giving in general thereby an absence of any means for propagating an extension of the infection to a new host, and with the fact that the ameba under such conditions is not in an optimum environment for both forms of reproduction.

Under conditions favorable for its growth and reproduction, the ameba exists in a free-moving form, while under less favoring environment and when preparing for departure from its human host, it encysts in a resistant resting form. We have no evidence that under any circumstances E. histolytica can inhabit the human colon as a harmless commensal. As the infection increases in quantity and virulence, the clinical picture approaches that of dysentery. On the other hand, as the infection is less massive and vigorous, the clinical picture is that of non-dysenteric amebiasis, that is, of a carrier or chronic state. As various authorities have pointed out, granted an amebic infection, it is evident that this chronic or non-dysenteric state is the optimum both for parasite and for host. Non-dysenteric amebiasis is much more prevalent in temperate climates while dysentery and abscesses are more frequent in hot climates.

Several comments arise out of this survey of the pathology and life history.

1. All forms of amebiasis, in our present state of knowledge, pre-suppose and require that primary form of intestinal infection just described.

2. The ameba can invade the blood and lymph stream with the utmost ease. This is further proved by the occurrence of liver and brain abscesses. But thus far, no portal of entry has been proved except the one noted through the intestine.

3. While the ameba gives evidence of secreting a histolytic exotoxin, no other evidence of exotoxic action has been clearly demonstrated.

4. All clinical symptoms resulting from the presence of ameba in the body must be due to the following mechanisms:

(a) The effect of local pathologic changes in the intestine or other tissues directly invaded by the ameba.

(b) Absorption of amebic exotoxins of a more or less hypothetic nature.

(c) The absorption through amebic lesions of virtually parenteral protein or bacterial products. This latter is probably the explanation for the inflammatory reaction and enlargement of lymphatic glands draining regions of amebic invasion.

(d) Reflex effects resulting from the presence of amebas in the colon or elsewhere. If an inflamed appendix can be responsible for a reflex constipation, it is equally conceivable that an amebic lesion can cause intestinal and digestive disturbances through a reflex mechanism.

As seen in California, amebiasis in the great majority of cases is of the non-dysenteric type; that is, the infection exhibits an approximate balance between host and parasite and is apt to manifest itself in symptoms which are not a direct result of the lesion in the intestine. Almost any variety and degree of neurasthenia, physical depression, constipation, loss of weight, anemia, digestive troubles, vague aches and pains, and indefinite ill-health may be associated with amebiasis and disappear when the ameba is eliminated. In fact the symptoms may be so diverse, bizarre and unexpected that amebiasis is the last possibility to

be considered. This type of symptomatology is prevalent in California. In view of these considerations the following clinical rules may be drawn with conservatism:

1. Amebiasis is prevalent in California in non-dysenteric form.
2. Every patient suffering from gastro-intestinal symptoms should be investigated for the presence of ameba.
3. Every patient in whom the diagnosis is obscure or incomplete should be investigated for ameba.

Identification of ameba in the stools must include at least six consecutive daily specimens, including formed as well as fresh liquid stools, and must be conducted by a competent parasitologist.

Pathogenic amebas, that is, E. histolytica, have been described with certainty only in the intestine and in secondary abscesses as in the liver, lungs and brain. Reports of their occurrence elsewhere in the tissues of the body are subject to more or less criticism and are either inaccurate or premature at the present time. By many writers pathogenic amebas have been described in the urine and urinary bladder. Some few of these reports may be correct but the majority cannot be studied without the growing conviction that inflammatory or body tissue cells have been confused with amebas. We must recall that the leucocytes of normal blood have an ameboid motility and a cytology distinguishable with the utmost difficulty in fresh preparations from motile pathogenic amebas. This point was called to my attention by Herbert Gunn, who has been able to demonstrate the close similarity of fresh leucocytes with various wandering tissue cells, pus cells and amebas. Error is difficult to exclude. Always study of the free-moving forms must be amplified by identification of cysts when they occur, description of the nuclear structure and study of stained preparations before a valid opinion can be given. These criteria have not been met in the great majority of cases where amebas have been reported present in the urinary tract and elsewhere in the body outside the points of recognized incidence.

The same criteria may be brought with equal force against amebas reported in any tissue, as in the skin for instance. In the case of bile infections, a final word cannot be given. Gunn has had cases, one of which he has reported, where intestinal amebiasis cleared temporarily after removal of the gall bladder which apparently contained motile amebas. Permanent cure was prevented possibly by amebic infection in the bile ducts. It has been supposed that ameba would not live in the presence of bile so here, too, further light is needed.

There is little question that many persistent cases of amebiasis depend for their chronicity on an amebic focus in the appendix. It is probable that removal of the appendix would cure many such cases just as effectively and much more quickly than appendicostomy and colon irrigation through the stump. Skin infections have been described, partaking of the nature of a phagedena and associated with sinuses from a deep amebic abscess as in the liver. It is conceivable that amebas might infect cutaneous tissue by this method but the proof of it is not very definite.

The problem of the relations of ameba to the lesions of arthritis deformans, Ely's second great type of arthritis, has received considerable study in the past year at the Stanford Medical School. For several years claims have appeared in literature that ameba was related to this hypertrophic type of chronic osteo-arthritis. In 1906 Hunkin and Long, in San Francisco, attempted to show such a relationship. Since then John Barrow of Los Angeles has claimed that the relationship existed.

In the late summer of 1921 Barrow found E. histolytica in the stools of one of Ely's patients who suffered from hypertrophic arthritis of the spine. Relief or improvement not having followed the usual methods of treatment, this patient was given a course of specific amebic treatment with an immediate and remarkable clinical improvement. One relapse of arthritic symptoms was accompanied by a recurrence of cysts in the stools and the symptoms disappeared with a continuance of treatment. A second relapse was not accompanied by any evidence of intestinal amebiasis but improvement again followed resumption of amebic treatment, and has continued.

About this time Ely removed the head of a femur for this type of arthritis. Sections from the necrotic areas of this bone were stained with a standard iron hemotoxylin method and showed cellular bodies identified as E. histolytica. These bodies were abundant near the periphery of the necrosis and especially abundant around the capillaries. Their identification as amebas has not met with unanimous confirmation from those who have examined the sections. They were studied by Kofoid, who has already this afternoon detailed his conclusions about them. In an earlier note Kofoid and Swezy make the following statement:

"A portion of the head of a human femur, removed by operation in a case of arthritis deformans, reveals a pure infection of amebae about the characteristic lesions in the bone. No stained bacteria have been found in our examination. . . . The organisms interpreted by us as amebae are unlike known normal or pathologic tissue cells. They have the clear nuclear structure of Endamoeba dysenteriae (Councilman and Lafleur) found in tissues about amebic ulcers in intestinal amebiasis. Their nuclei are unlike those of endamoeba gingivalis."

Ely, Wyckoff and I have continued investigation of these lesions and have examined the stools in twenty cases of Type II arthritis in the clinic service. Of these only one showed histolytica. This patient was put on intensive treatment for amebiasis with the result or accompaniment that his arthritis became distinctly worse and remained worse. Cysts had not reappeared in his stools within two months after stopping treatment but physiotherapy had to be resumed to relieve his pain.

During the same period I saw seven other cases

of Type II arthritis. One only of these, the case already mentioned as the original in this series, harbored Entamoeba histolytica. One of these which had no evidence of amebiasis was put on moderately severe amebic treatment none the less and received immediate improvement which has lasted for some two months. I believe the explanation lies in the free elimination secured by the treatment and is along the line frequently noted of improvement following the use of colon irrigations and a diet designed to decrease putrefactive changes in the bowel. A second case was infected with an ameba which Kofoid diagnosed as Councilmania. The amebiasis was cured by specific emetin treatment and the clinical improvement was marked and has lasted some three months. Such a so-called therapeutic test as this seems to me worthless, however, as showing any relations between ameba and arthritis, for the same reason as stated above.

It is evident that bony changes in hypertrophic arthritis will outlast removal of the specific cause whatever that may prove to be, and it is more than possible that the symptoms of arthritis would persist likewise after removal of the specific cause. Effective treatment probably must be instituted in the early stages of the bone pathology and preferably on a preventive basis. Immediate improvement in the symptoms of arthritis after treatment with emetin preparations would in no sense argue for an amebic cause for the arthritis, but rather for immediate removal or subsidence of some focus of toxic absorption in the intestine. This is in line with mature clinical judgment.

Settlement of the present question of the causative relationship of the ameba will depend not on therapeutic experimentation but on demonstration of definite association histologically between ameba and bone lesion, and the experimental production specifically of such lesions.

It might be assumed that a comparison of the rate of incidence of ameba in Type II arthritis cases as compared with the rate of incidence at large would give conclusive evidence for or against the thesis that ameba is the cause of osteo-arthritis. But it is to be remembered that such statistics are at best only of inferential value and what value they possess is strictly proportioned to their quantity. Definite pathologic evidence alone would satisfy the requirements of the case.

This investigation is tedious and slow in its development and a considerable time will be required to affirm or disprove the suggestion that ameba is related to arthritis. Ely finds alveolar infection almost universal in Type II arthritis, yet the bone lesions seem without question to be non-bacterial in origin and, moreover, the E. gingivalis, so frequently associated with abscesses and granulomata in the dental area, has so far not been proved pathogenic. In a recent case of intestinal amebiasis, we examined the carious bone resected for the removal of deep dental infection. In the dental abscesses and granulomata E. gingivalis was abundant but no ameba-like cells of any sort were found within the bone itself. Nevertheless we are not yet prepared to state positively that the alveolar process can never be a portal of entry for pathogenic amebas.

Clinical experience thus far is too small to warrant statistical conclusions and for the purpose involved here, the importance of statistics is certainly minimal. We know that in other regions ameba may leave certain areas and move on or disappear, and the same factor doubtless would play a part if amebic bone infection were to occur.

There is, on the other hand, no evidence that amebiasis ever terminates spontaneously in the absence of specific treatment. Our personal impression is that the matter of bone invasion by ameba requires adequate investigation and that the suggestive data at hand amply justify further study. Lacking a bacterial cause for arthritis deformans, we can with logic seek a protozoal cause. Barrow believes that protozoan infection is present in 100 per cent of Type II arthritis. It will be necessary to demonstrate motile amebas in the fresh bone tissues, as cysts are not to be expected in such a location. As E. histolytica has not yet been successfully cultivated, experimental lesions are extremely difficult to secure at present.

While it is not certain that the intestinal tract is the sole portal of entry for pathogenic amebas, still thus far no other has been demonstrated. Treatment of intestinal amebiasis, therefore, might react favorably on a bone lesion in a non-specific manner by decreasing absorption of bacterial or protein products through intestinal ulcerations. The field of investigation is large and many unknown factors are doubtless involved. It is possible that a food deficiency analogous to a scorbutic deficiency may determine the bony localization of a protozoan parasite. We are convinced in any case that the inquiry must proceed along pathologic and experimental lines rather than in the hope of data from therapeutic or statistical methods in well-established cases of arthritis.

An unusual case of amebiasis was seen recently through the kindness of W. H. Barnes of San Francisco who reported it at the April meeting of the Stanford medical staff, and who intends to publish the detailed case report after longer observation.

A young woman, who had served as an army nurse, had suffered for five years from attacks of unusually severe asthma. During the same period she had recurring periods of diarrhea and sometimes of dysentery. No cause being found for the asthma, the stools were finally examined and E. histolytica was found in heavy infection. Specific treatment resulted in the temporary disappearance of the ameba and also in immediate relief of the asthma. Recurrence of ameba in the stools for a considerable period were concomitant with recurrences of severe asthma, which each time were relieved by specific treatment for amebiasis. Finally a more severe course of treatment was instituted with the hope of entirely eradicating the ameba, and in the course of the treatment she developed a severe arthritis. This is her status at present and Barnes' future report will record the end results.

Ordinarily asthma in the course of amebic infection is not affected by treatment for the latter.

The striking coincidence of the asthma and the intestinal symptoms and their common relief by specific amebic treatment are remarkable. The relation, if any, of the arthritis to the other conditions present has not yet been suggested.

In the treatment of amebiasis we believe that ipecac and its alkaloids alone are of value. Emetin hypodermically and bismuth emetin iodide by mouth are the only two preparations used, with the occasional addition of ipecac root. Neosalvarsan is added on the strong recommendation of Herbert Gunn who has found it to increase the efficiency of treatment. The bismuthous emetin iodide is given in powder form in gelatin capsules, three grains at night, if necessary preceded by opium. This drug is difficult to take and sometimes cannot be used in full dosage. Colon irrigations and oil enemas are used where there is evidence of marked colitis. Under like conditions the treatment is initiated by a short course of ipecac powder in massive doses. Other drugs are used solely for symptomatic indications, as for the benefit of digestion or the relief of colitis which may and often does outlast eradication of the ameba. Synthetic emetin is under trial at the suggestion of Barrow.

Treatment should be intensive and repeated milder courses administered in case of recurrence of cysts in the stools. Some cases have received definite benefit by resumption of mild treatment for purely symptomatic reasons when no cysts could be discovered. Alcresta ipecac is used at times for this purpose. It is mild in action, and much weaker than other ipecac preparations named, probably due to its admixture with kaolin.

The chief criterion of cure of amebiasis is the absence of cysts from the stools for a period of at least three months after termination of treatment. Examination for cysts, as already stated, requires at least six consecutive specimens on different days, including formed as well as fresh liquid movements.

In our investigations at the Stanford Medical School the stool examinations have been under the direction of Harry A. Wyckoff, clinical pathologist at Stanford Hospital.

USING MEDICAL TERMS BEFORE PATIENTS

During the days when frock coats and whiskers were part of the physician's stock in trade, it was quite the custom for physicians to bewilder and frighten the patient by discussing his illness in Latin or in technical terms the patient could not understand. This custom should have disappeared with the frock coat, but it has not entirely done so.

The practice is and always was a deplorable example of poor taste, and now it is no longer legally safe. Many patients are sufficiently acquainted with the technical terms to understand, while others misunderstand and cause themselves worry and unhappiness.

In a number of court actions recently, physicians have been required to substantiate thoughtless statements made at the bedside, and it is likely that evidence of this kind will play a more and more important role in malpractice suits as time goes on.

A PLAN FOR THE INTENSIVE TREATMENT OF CONGENITAL SYPHILIS

PRELIMINARY REPORT

By HERMANN SCHUSSLER, JR., M. D., San Francisco.

The average physician, more particularly the general practitioner, has always considered the treatment of congenital syphilis as a most unsatisfactory part of his work. While many patients, especially young infants, show a strikingly clinical improvement under the influence of mercury alone, yet the Wassermann reaction is hardly ever made negative even when this drug is long and faithfully continued. The late case, with interstitial keratitis or a bone lesion, is generally looked upon as essentially incurable. Furthermore, many physicians feel that intensive arsenical therapy is either too difficult, too dangerous, or too painful to be used in infants and young children, except perhaps in the hands of one highly trained, and with all the facilities of the modern hospital at his disposal.

Recently Fordyce and Rosen, and Jeans have presented evidence that by following out in congenital syphilis a systematic plan of treatment similar to that used in adults, remarkable results can be obtained. Infants were apparently cured within a year, and most older children in two years. The methods described by these writers are not only efficient but safe, and simple enough to be carried out by anyone with medical training.

For the past two years we have been gradually improving, simplifying, and systematizing our routine plan of treatment for congenital syphilis at the Children's Clinic of Stanford University Medical School. Our aim has been to develop a method which the general practitioner can apply in the office or the home with a minimum of apparatus and trouble, with little or no discomfort or risk to the patient, and with the assurance that all the advantages of modern intensive anti-syphilitic therapy have been brought to bear upon the case. The method as it now stands may require further changes in the future, but we feel that the work has progressed far enough to justify this preliminary report.

General Plan of Treatment—When the Wassermann report comes back positive, the parents are carefully instructed as to the nature of the infection, the prognosis to the child with and without treatment, and the importance of regularity in attendance and of following out instructions to the letter. Wassermann tests are done on the parents and their other children, and the importance of treating the mother during future pregnancies is emphasized. The whole-hearted and faithful co-operation thus secured has contributed markedly to our good results.

If no contra-indication is found in the physical examination, the following course of treatment is begun at once:

1. Three intravenous injections of neoarsphenamine are given at 48-hour intervals.
2. Three mercurial inunctions are given every week for eight weeks.

3. Three more neoarsphenamine injections are given at 48-hour intervals.
4. Mercurial inunctions are given as above for four weeks more.
5. A rest period of four weeks is permitted, at the end of which a Wassermann test is done.

It will be noted that the above schedule covers a period of about four months. It is repeated regularly until the Wassermann test is negative, after which one more course is given with step 3 omitted. Then all treatment is stopped, and the Wassermann is repeated every six months for three years. If all are negative, and no clinical evidence of the disease has appeared, the patient is considered as probably cured.

Perhaps a longer observation period would show some late relapses, but we believe that three years are sufficient for all practical purposes. We have given up the provocative Wassermann reaction as unreliable, and feel that routine spinal puncture before dismissal is not necessary in children.

Sodium iodide is given almost continuously to all patients over one year old, being omitted and a tonic of iron and cod liver oil substituted during the rest periods.

If the patient has an active or open lesion, the initial series of neoarsphenamine is increased to six injections on alternate days, the rest of the course being as usual. This first course is considered the most important, and it should be made intensive. In weak athreptic infants, the first arsenical series may be preceded by a week or two of mercury rubs.

Spinal puncture is done (1) if the central nervous system is clinically involved; (2) if the Wassermann reaction is very resistant to treatment; (3) in cases with mental deficiency, and (4) at the time of the first negative blood Wassermann, if involvement of the nervous system has ever been suspected. Intraspinal treatment in children is rarely used and is not recommended for general practice.

Adenotonsillectomy and extraction of diseased teeth should be done whenever indicated, not only because the child's general condition is improved by the operation, but because the clinical and serological response to treatment often becomes far more rapid and satisfactory after the removal of focal infections. The first rest period is usually the best time for such surgical measures.

Dosage—The dosage of neoarsphenamine varies with the age, weight, arsenical tolerance, and general physical condition of the patient. It is much higher, in proportion, than the doses commonly used in adults. We have never seen a serious reaction from it when given as advised in this paper.

The ampules are made in six sizes, and the following table indicates the usual weight-range for each size, as well as the amount of water generally used to dissolve the dose:

Dose	Weight-Range	Water
0.15 g.	Under 12 pounds	0.5 cc.
0.3 g.	12-22 pounds	1. cc.
0.45 g.	22-35 pounds	1.5 cc.
0.6 g.	35-50 pounds	2. cc.
0.75 g.	50-70 pounds	2.5 cc.
0.9 g.	Over 70 pounds	3. cc.

Of course, in any case whose arsenical tolerance is doubtful, the initial dose should be about half the usual one for the patient's weight.

The mercury is prescribed as flexible capsules, each containing 4 g. of the official 50 per cent Unguentum Hydrargyri. Parents and children are instructed to rub for 30 minutes or until the skin no longer feels greasy, after which the excess may be removed with benzine and cotton. Infants under 20 pounds are given two inunctions a week of half a capsule each, using alternately the front and back of the body from neck to knees. Children between 20 and 50 pounds get half a capsule three times a week, the areas used being (1) chest and abdomen, (2) back, and (3) both legs from hips to ankles. Children over 50 pounds get a whole capsule three times a week, using the same areas. Older children do the rubbing themselves, except when the back is used.

Sodium iodide is prescribed in saturated solution, one or two drops for each year of age three times a day after meals, given in a full glass of milk. The initial dose is often smaller as a precaution, although we have seen no iodism. Larger doses than those given above are probably never necessary, even when gummata are present.

Half a teaspoonful of powdered sulphur at bedtime every night is an efficient prophylactic against mercurialism, as well as a useful treatment for this condition when it occurs. In the rare cases in which a gingivitis developed, the sulphur cleared it up rapidly, although the mercury was continued without interruption. When mixed with a little syrup, children take it without objection.

Neoarsphenamine Technique—We use a modification of Schamberg's technique. A 2 cc. glass syringe, an ordinary Wassermann needle, and a half-inch, 25 gauge hypodermic needle comprise all the apparatus required. After sterilization, the specified amount of boiled fresh *tap* water is drawn into the syringe, and the larger needle attached. Distilled water, and larger amounts of water than those given in the table, are unnecessary. The small tip of the ampule is filed and knocked off, the powder shaken to break up lumps, and the cooled water injected. The finger-tip, wiped off with alcohol or covered with a sterile finger-cot, is placed over the small hole, and the ampule is well shaken until solution has occurred, usually in less than one minute. The solution is now drawn into the syringe from the inverted ampule. The large needle is then replaced by the smaller one and the injection given *at once* to prevent oxidation.

Children of over six years usually have good veins at the bend of the elbow. In all others the external jugular is probably the best, although young infants often have good scalp veins which may be used. We no longer use the fontanelle, and do not recommend it. Crying, or digital pressure above both clavicles simultaneously, will distend the jugular and scalp veins nicely. For the former, the head should be hyperextended and rotated, with a pillow under the shoulders. The skin is washed with 95 per cent alcohol, as 70 per

cent leaves it slippery. The distended vein and overlying skin are drawn taut by the operator's left thumb. The small needle is introduced well into the vein by a quick stab, which is practically painless. When the blood enters the syringe by gentle traction with the plunger, and the point is known to lie free in the vein, the digital pressure is released and the injection is made slowly, taking about one minute. When the syringe is empty, 0.5 cc. of blood is aspirated and reinjected, to rinse out the last drops of solution and prove that the needle was in the vein throughout. Obviously, the child must be prevented from struggling during the treatment. Most children are quiet after their first experience.

This technique is no more difficult than that required for other intravenous medication. It takes less than five minutes to give a treatment, and the same vein often may be used repeatedly. The small syringe and fine needle make these intravenous injections simple even in the smallest vein. We have never had to cut down on a vein, and have given up rectal and intramuscular administration entirely.

Comment—The dosage and intervals recommended above have been reached very gradually and they appear to be the most satisfactory ones for general use. Whether children tolerate neoarsphenamine better than adults, or whether the customary dosage in adults is too small, is not certain. However, our dosage is safe, and has been exceeded on several occasions without untoward results. In view of the low toxicity, high efficiency, and ease of administration of neoarsphenamine, we feel that it should entirely replace arsphenamine in the treatment of children. It is extraordinary to one accustomed to giving 0.6 g. of this drug once a week to an adult to see a child weighing 35 pounds taking the same dose every other day for six doses with no sign of a reaction. Reactions, other than a little vomiting at times, are practically eliminated by omitting luncheon, making breakfast and supper light, giving a mild laxative the night before if the child has been constipated, and giving the injection between 11 a. m. and 3 p. m.

The 48-hour interval recommended by Ormsby is safe and far more efficient than the longer intervals in common use. In following somewhat similar methods we have not observed anything suggesting a cumulative toxic effect.

The contra-indications to the various drugs employed are the same in children as in adults, but are comparatively rare. None have occurred in our series. The occasional appearance of a trace of albumen and a few hyaline and granular casts in the urine during the administration of the neoarsphenamine may be disregarded, as they always disappear rapidly after the last injection, and do not indicate nephritis.

Inunction is the method of election in giving mercury to children. Mouth administration clears up lesions and increases weight, but does not affect the Wassermann reaction and also has the other well-known disadvantages. Ramsay and Groebner have shown, by quantitative analyses of the urine for mercury, that absorption after proper inunctions was greater than after any other method which they tested. They also showed that daily inunctions are unnecessary, and since we have adopted the present plan of two or three rubs a week, no patient has failed to carry out his part of the program faithfully. We have seen no salivation, diarrhea, or dermatitis.

RESULTS AND CONCLUSIONS

While a number of our patients have been rendered Wassermann-negative, and all have shown marked clinical improvement, as evidenced by disappearance of lesions, gain in weight and strength, and better work in school, yet we feel that a statistical presentation of our results should be postponed until a longer observation period has elapsed. The hope of the congenital syphilitic lies, we believe, in more systematic planning of his treatment, in its continuance beyond the first negative Wassermann, and in the use of larger and more frequent doses of neoarsphenamine than have heretofore been customary. In any case we are more than satisfied with the progress our patients are making, and feel that our plan of treatment, while extremely simple and easily mastered by anyone, is as effective and as well borne as any that has heretofore appeared in the literature.

Resolution on Chiropractic Training of Disabled Soldiers—Abstract from Minutes of the Seventy-Third Annual Session of the A. M. A.

"Whereas, The St. Louis Medical Society on May 16, 1922, by Memorial and Resolutions vigorously protested against the approval by the U. S. Government of the School of Chiropractic as a means of vocational training for disabled ex-service men, and

"Whereas, It appears that more than 250 ex-service men from all parts of the country, seventy of whom represented the Ninth District, composing the States of Missouri, Iowa, Kansas and Nebraska, are now enrolled in one Chiropractic School in this district with the sanction and approval of the U. S. Government; therefore, be it

"Resolved, That the House of Delegates of the American Medical Association, in annual session assembled, representing over 89,000 legally qualified physicians, adequately trained in the arts and sciences (the only foundation for the recognition, control and prevention of disease), approves the sentiments expressed in the Memorial and Resolutions adopted by the St. Louis Medical Society, which have been submitted to this House, and hereby directs that the proper officers of the American Medical Association memorialize and petition the Federal Government, particularly those officers charged with the responsibility for the rehabilitation of disabled ex-service men, and to take such action in the interest of the welfare of all the people, and also for the protection of those who honestly desire to administer to the sick, to the end that the ex-soldiers seeking vocational training, which will fit them for administering to the sick and aiding in the recognition, control and prevention of disease, shall, at least, meet the requirements and shall receive such adequate training as is defined in the classification of medical schools of the American Medical Association, known as Class A, or acceptable medical schools—a standard which is approved by all right-thinking people moved by a desire for public welfare."

THE DIPHTHERIA PROBLEM

By W. W. ROBLEE, M. D., Riverside, California

Notwithstanding a fairly complete knowledge as to etiology, methods of immunization and specific treatment, diphtheria continues to take a serious toll of lives and is responsible for great economic waste.

Number of cases of diphtheria in New York City, 1920 14,166
Number of deaths from diphtheria in New York City, 1920..... 1,045
Number of cases of diphtheria in New York City, first six months, 1921..... 10,722
Number of deaths from diphtheria in New York City, first six months, 1921..... 611
Estimated cost for first six months, 1921.....$581,825
Number of cases in California, 1921..... 9,448
Number of deaths in California, 1921..... 637
Number of cases last two weeks in January, 1922. 637
Total deaths annually in United States about.....15,000

Prior to 1895, when antitoxin came into general use, the case rate was variously estimated at from 150 to 200 per hundred thousand. Many factors render it difficult to arrive at accurate figures, but apparently the disease incidence has been very little reduced during the past decade.

The mortality rate in pre-antitoxin days was 32 per cent.

The mortality rate at present is but 8 per cent.

This gives a mortality reduction of 75 per cent, or, in other words, antitoxin saves 45,000 lives annually, but the disease incidence remains stationary.

The object of this paper is to call attention to certain proven procedures, whereby disease incidence, in relation to diphtheria, may be greatly reduced. In fact, it is not an over-statement to declare that clinical diphtheria could be wiped out if universal application of these methods could be secured.

Two Necessary Factors in Diphtheria Control:

1. The spread of infection by:
   (a) Carriers:
      1 per cent of population, 4 to 8 per cent of children have either virulent or avirulent bacilli.
   (b) Missed clinical cases:
      (1) Pharyngeal.
      (2) Nasal.
      (3) Laryngeal.
2. Detection of those non-immune by:

   Schick Test. This was published in 1913 and used extensively by Behring in Germany eleven years ago and by Park & Zingher in New York for the past nine years. Over 100,000 children have been tested in New York during that period and numerous smaller groups elsewhere.

Technique of Schick Test:

1/50 minimum lethal dose of diphtheria toxin for a 240 gram guinea pig in a given quantity of salt solution, usually 0.1 cc., is injected intradermally, preferably on the anterior surface of the forearm and the same amount of the toxin heated to 75 degrees C. for ten minutes is given in the other arm. Dilutions must be freshly prepared each day.

The Toxin Reaction:

"Represents the irritant action of a specific toxin upon tissue cells that are not protected by antitoxin." It therefore shows a lack of immunity. The control test is for the purpose of detecting those who are sensitive to the proteins of the meat extracts and peptones used in the culture media and to the bacillary proteins that cannot be eliminated by any known method. In 24 to 72 hours a red area from 2 to 6 cm. in diameter develops; this is at its height on the fourth to fifth day and gradually fades, leaving a slightly scaly, brownish pigmentation which may persist for several weeks. Pseudo reactions develop quickly and are at their height in 24 hours. They disappear in three days.

Defined as: (1) Positive; (2) Negative; (3) Positive combined, when both the toxin and control react; (4) Pseudo or pseudo-negative, a protein reaction.

There are no constitutional effects or painful local reactions from this test.

Results of the Toxin Reaction:

Age—Under six months all have maternal immunity. From six months to five years nearly all are non-immune. After five years the immunity per cent gradually rises, probably due to mild repeated contact infections. The per cent positive varies in New York City from 16 to 67 per cent in various schools. Age, race, family and housing conditions have their influence. A fair average in children, including high school age, is 25 to 30 per cent positive. Therefore we can say that babies under six months have maternal immunity. Children from six months to five years should all be immunized without going to the trouble of giving Schick test. Children over five should be Schick tested and all positives immunized.

Artificial Production of Permanent Immunity:

1. Ordinary antitoxin immunity lasts only two to four weeks.
2. Toxin antitoxin.

   A highly concentrated diphtheria toxin is slightly underneutralized by a concentrated antitoxin. One cc. of this mixture should give a small reaction in a 250 gram guinea pig. A 5 cc. dose should develop a paralysis in 15 days, and death of the pig two or three days later. It requires about six months to produce a stable standardized mixture and this will retain its stability for a year. Three of these 1 cc. doses at seven-day intervals are given. The toxin is neutralized to the extent of not being poisonous and yet it has the power to stimulate antitoxin production. The injection for all ages is 1 cc. of fluid, containing about 400 times the fatal dose for a half-grown guinea pig to which has been added slightly less than the antitoxin necessary to neutralize it. The reaction is usually slight, but in susceptible individuals may be fairly sharp. It is usually less than from typhoid-paratyphoid injections and more pronounced in those giving a positive combined reaction by Schick test.

Immunity:

Develops completely in about two months. Therefore it is of no service in the treatment of clinical diphtheria. Contacts can be immunized temporarily by antitoxin and in one month the permanent immunization done by toxin antitoxin; 85.5 per cent give negative reactions after five months. One or two additional injections should be given to the 14.5 per cent whose immunity is not complete. It is therefore wise to retest at the end of six months from initial immunization; 100 per cent remained immune after being handled as above by Park & Zingher in an institution five years ago. It is therefore safe to say that in all probability a complete permanent immunity can be developed by the above plan.

Cost of Immunization:

$1.25 per patient when a small number are treated. When large numbers are to be immunized the expense is much reduced. It is estimated that the one million school children of New York City could be immunized for $250,000, which is about $332,000 less than diphtheria cost New York City during the first six months of 1921.

The objection has been raised by Cumming and others that Toxin-Antitoxin immunization is dangerous to the community for the reason that it does not destroy the infecting organism and that it in no way diminishes the number of carriers. That cities in which toxin-antitoxin protection is pushed will "become reservoir hosts of bacilli." There is no reason why efforts looking toward the elimination of carriers should be discontinued but the solution of that problem is at present hopeless. The one per cent of carriers in every city community and the activity of the various antagonistic cults renders such efforts largely of no effect. Doctor Park reports that deaths from diphtheria in New York City have been reduced from 1500 in 1918 to 891 in 1921, and he believes that both morbidity and mortality can be further reduced by a continuation of intensive work with the Schick test and toxin-antitoxin immunization. It certainly will solve the problem in schools or institutions where the inmates are under sanitary control.

Student nurses in every training school should be tested and immunized. It is our duty as physicians to call the attention of parents to the

fact that this dread disease can be prevented. My own children have been immunized and it was a great comfort to me a few weeks ago, when my little five-year-old daughter developed a membrane on her throat, to know that it would not result in the development of a laryngeal stridor and that she would not require sensitization by large doses of horse serum. It proved to be a streptococcus infection.

The efficacy of these measures in an institution was beautifully illustrated by an experience that we have had during the past year at the Sherman Institute Indian School, Riverside. In June a group of children from Arizona arrived at the school from a portion of the Navajo reservation, where diphtheria had been prevalent. On June 24 one of these pupils came down with clinical diphtheria. Others developed from time to time and as the school enrollment was low at that time of year, only about 300 pupils remaining, we cultured all throats and found 32, or 10 per cent to be carriers. These were isolated and released as they became negative, two requiring tonsillectomy. The disease was apparently controlled until October when, following entrance into the school of another group of children from a diphtheria-infected community, it again became prevalent, sixteen clinical cases developing before it finally came under control. There were at this time over 700 pupils enrolled in addition to which there were over one hundred white employees and members of their families on the grounds.

Early in December 641 pupils were Schick tested; of these 351 gave positive reactions. The positives were all immunized by three injections, at weekly intervals, of toxin-antitoxin, and also 53 Indians at the school farm and 17 white employees' children who were not given the Schick test, making a total of 420. The last dose was given December 24, 1921. The results obtained were most interesting. Four clinical cases of diphtheria developed after the last immunizing dose was given, two on January 5th, one January 15th and one January 20th. These were all very mild and did not require antitoxin for their cure. These cases bear out the observations made by others, that full immunity does not develop immediately, but that the severity of the case reaction gradually becomes lessened until full immunity at the end of about two months is developed.

During January, February and March, thirteen cases of tonsilitis developed, some of which showed membranes that could not be differentiated clinically from diphtheria. One case on February 28th suggested diphtheria so strongly that I gave antitoxin at once, but cultures when examined the next morning gave only a staphylococcus growth. No clinical cases of diphtheria developed among Schick negative students. Every check and cross check in this observation proved the fact that the Schick test and toxin-antitoxin immunization can be depended upon to control clinical diphtheria even under the crowded conditions found in a government Indian school in a group of young people with very low racial immunity.

I desire to acknowledge the helpful assistance of my associate, Dr. T. A. Card, in this study.

SUMMARY OF AN IDEAL PLAN FOR HANDLING DIPHTHERIA

I. To Protect the Community:
  1. Clinical cases:
    (a) Antitoxin treatment.
    (b) Quarantine.
    (c) Release after three negative cultures.
  2. Contacts cultured:
    (a) Negatives released.
    (b) Positives given virulence test.
      (1) Isolate in open air.
      (2) Mild alkaline gargle.
      (3) Tonsillectomy if the carrier condition persists for a month.
      (4) Release avirulent.

II. To Protect the Individual:
  1. Schick Test all over five years to full maturity.
    (a) Babies under six months maternally immune.
    (b) Six months to five years all should be immunized by toxin antitoxin.
    (c) Five years and upward Schick Test.
      Immunize positives by three injections, 1 cc. toxin antitoxin mixture.
      Retest in six months and further immunize those still positive.

The Country Doctor—The election of Thomas Clay Edwards as president-elect of the Medical Society of California has called forth a number of editorials and other comment from a number of papers of the State. Among these, the San Jose News, of May 26, 1922, says:

"A few weeks ago Dr. T. C. Edwards, for forty years a general practitioner in Salinas, was elected president of the California Medical Society. His election was announced as a 'tribute to the work of the country doctor for humanity.'

"The tribute is well deserved by the country doctor. For while this is notoriously and flagrantly an age of specialization, basic general all around horse sense is a quality which is just as valuable as it ever was. The country doctor, the general practitioner, while he may occasionally blunder because he can't keep up with all the latest information on the progress of the various special divisions of the art he practices, yet seems to retain this grand old quality of basic horse sense to a great degree, whereas some of the specialists in medicine, as in other lines, seem to have more fancy zebra sense, or even jackass sense, than plain horse sense.

"Hurrah for the country doctor, the old fashioned general practitioner. He may have killed lots of people, but so has the specialist."

A Salinas paper of May 30, after paying splendid tribute to Dr. Edwards and complimenting the medical profession of the State for selecting a country doctor for its president, continues as follows:

"A lot of near-facetious comment, and 'smart aleck' cracks have been launched at the small town doctor. Just because he stays in the small town a lot of people get an idea that he isn't so efficient as his brother in the larger cities. That's all wrong. The big town chap handles only a certain line of diseases, 'Specialist' is what he calls himself. The country doctor is called to treat everything from an in-grown toe-nail to a broken back. Most of them could give the so-called 'city specialist' a close run in the latter fellow's particular line. You simply have to doff your tile to the country doctor. He's one grand scout. Generally he knows more community history, scandal and gossip than anyone in his section. But he's a close-mouthed business-like, genial, lovable mortal who undergoes a lot of things that would drive a lot of us to the goofy house. Salinas appreciates the honor done Dr. Edwards. Her people extend congratulations. The honor to him is no less an honor to every doctor in Salinas, and—for that matter—to every country doctor in the whole land. May God bless 'em—every one of 'em.

IS THE MELTZER-LYON TECHNIC FOR THE DIAGNOSIS AND TREATMENT OF GALL BLADDER DISEASE AN ASSET OR A LIABILITY?*

By WALTER C. ALVAREZ

PART I.

In 1917 Meltzer suggested, first, that inasmuch as the sphincter at the end of the common duct presumably must relax when the gall bladder contracts, if the contents of the gall bladder are to be extruded into the duodenum, the activities of the sphincter and the bladder must be coordinated and under the control of the "Law of Contrary Innervation." Second, if this be true, magnesium sulphate, when it relaxes the sphincter, must theoretically cause a reflex contraction of the gall bladder. Third, if magnesium sulphate were to be injected into the duodenum, it might help in overcoming jaundice and biliary colic.

The third suggestion was immediately put to the test by Vincent Lyon of Philadelphia. He observed that when the duodenal tube is first passed into the bowel, little or no bile can be withdrawn. Shortly after the injection of the magnesium sulphate, yellow bile appears; and shortly after that, there appears a darker and sometimes thicker bile. He assumed that the darker bile must come from the gall bladder, and the next step was to diagnose cholecystitis by the finding in this bile of pus cells, crystalline material and bacteria. Another step was to try to cure cholecystitis by repeated "drainages."

Certainly if Lyon is right in his contention this new method of diagnosis and treatment will be a great asset to the medical profession. If, however, the method is not based on a solid foundation; if it will lead to the making of wrong diagnoses and the performance of unnecessaray operations; if it will cause physicians to waste their time and their patients' time and money; and if it will encourage patients to go on with futile medical treatment until old age, starvation, myocarditis and other complications bar the way to surgical relief, it will be a liability. As I have seen of late a number of cases in which the use of the method was ill-advised and its results unfortunate, it seems to me that we must not drift along using "biliary drainage" simply because it is being done, but as scientific physicians we must stop for a few minutes to see how much grounding it has in physiologic fact, and how much likelihood there is of its ever being able to clear up the diseased conditions which we find in cholecystitis.

A review of the large literature which has already grown up about the subject shows that, for the most part, the clinical reports are very favorable. That is to be expected with any new form of treatment. On the other hand, nearly all the reports on work done in an attempt to determine the accuracy of Meltzer and Lyon's physiological contentions have served to cast doubt upon them and upon the method derived from them. In the first place, Meltzer's original theorem of a contrary action has been pretty thoroughly discredited by the finding that a number of substances besides magnesium sulphate will produce the typical flow when they are injected into the duodenum. As most of these drugs do not relax the sphincter, it cannot be argued that they will reflexly stimulate the gall bladder. Furthermore, it cannot be shown on either animals or men that the flow of bile produced by magnesium sulphate is accompanied by a contraction of the gall bladder. It seems clear now that that organ is a weak and sluggish one which never contracts down like the urinary bladder does, even when it is stimulated directly by strong electric currents. When it does contract it produces pressures of at most 30 mm. of water, barely enough to overcome the resistance of the valves in the cystic duct. The writer has tried several times to stimulate the gall bladders of animals (anesthetized with urethane and opened under salt solution) into visible activity, but without success. We know also that at operations on men or on animals, the gall bladder is practically never found empty, as it would be if it occasionally squeezed out its contents. The available evidence suggests strongly that bile flows from the gall bladder, not because the muscle there has contracted, but simply because the pressure in the common duct has been lowered by the relaxation of the sphincter at the duodenal end.

Certainly, in the face of these physiological data, the users of the Meltzer-Lyon technic can no longer assume with any confidence that the dark bile comes from the gall bladder. There are a few experiments recorded which suggest that occasionally that may be the case, but most of them show conclusively that the color changes can be obtained in the entire absence of a gall bladder, that is, when that organ has been removed by operation or closed off by disease. It follows that if we cannot safely assume that the dark bile has come from the gall bladder we must not attempt to diagnose cholecystitis because we find bacteria or detritus in that bile. Furthermore, it must be remembered that although the duodenum contains fewer bacteria than does any other part of the bowel, it generally contains some; and it has been shown that an increase in their number will depend largely on the degree of acidity of the gastric juice, upon the amount of saliva swallowed, the sterility of the last food eaten, the condition of the teeth, etc. Another difficulty is that in a surprisingly large proportion of cases of gall bladder disease operated upon, no bacteria can be grown from the bile even with the most advanced cultural methods. Even in the presence of stones, more than 50 per cent of the biles are sterile. Unfortunately, few of the men who have tried to use the Meltzer-Lyon technic diagnostically seem to have been aware of these limitations and sources of error.

THERAPEUTIC PROBLEMS

It seems pretty clear from this review that as a diagnostic procedure the method has hardly a leg to stand upon. Let us see now if it fares any

* Read before the Section on General Medicine at the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

better when we come to examine its therapeutic pretensions. To begin with, we can admit two things: First, that it cannot be expected to have any influence on gall stones; second, that it may easily be of some benefit in the treatment of catarrhal jaundice. Even there, however, it is hard to say how much good it does because the patients get well anyhow, and one can never tell in a given case whether or not the period of illness has been shortened by the treatment. Thus, recently, one of my patients began to fade in about three days. If I had done as I had planned, and had given him one or two Meltzer-Lyon treatments, the outcome in his case would have furnished a strong argument in favor of the new technic.

The great difficulty in treating chronic cholecystitis is that we are faced with an infectious process which is localized not only in the walls of the gall bladder but, as Graham and Judd have shown, is generally scattered through the liver, through the glands about the cystic duct and often into the head of the pancreas. Even if we could clear up this infection with a few treatments, how could we hope to prevent its recurrence; and why should we expect a "non-surgical drainage" to succeed when the surgical drainage has so often failed? As is well known, a large proportion of the people who are relieved of their symptoms after operative drainage, return later for a cholecystectomy, because the infection has returned and new stones have been formed. Meyer, at the Hooper Foundation, has produced chronic recurring cholecystitis in animals simply by putting small foreign bodies into their gall bladders. This little handicap so lowers the resistance of the organ that although it may clear itself of the infection from time to time, it cannot remain clear. Similarly, a woman with gall stones or a scarred gall bladder, is subject to a flareup of infection whenever she has a cold, or whenever she puts undue strain on her digestive tract.

That being the case, it seems to me that there is only one thing to do with a chronically diseased gall bladder if we really want a cure, and that is to take it out. Individual cases will always have to be treated individually, however, and in the present state of our knowledge it is often hard to decide when a patient should be urged to go to the surgeon, and when she should be advised to let well enough alone.

I am glad to see that Lyon now admits that we must be careful how we speak of "cures" in an essentially chronic disease, and that he advises immediate operation in many of the bad cases. I agree with him that his technic is worth trying on certain people who for one reason or another cannot submit to operation, or who have had unsuccessful or partly successful operations. Furthermore, I think it should be tried in every rebellious case of catarrhal jaundice. The method may occasionally be helpful in establishing the presence of severe cholecystitis, but I would never think of relying upon it for the diagnosis of early or obscure forms of the disease.

LETHARGIC ENCEPHALITIS

By N. T. McARTHUR, M. D., Napa State Hospital, Imola, California

Epidemic Encephalitis began in Europe in 1916 and 1917, following in the wake of the influenza. Early the next winter the disease appeared in epidemic form in Paris. It then spread to England, where it was mistaken for Botulism, but the error was soon corrected by the investigation of McNalty, James and Marinesco and McIntosh. Encephalitis did not remain in Europe, but soon spread to Africa, Asia, Australasia and America, appearing here in the winter of 1918 and 1919.

It is interesting to note the spread of Encephalitis in America during the first six months of 1921. In New York there were 153 cases; in Connecticut 52; in Illinois 168; in Wisconsin 16; in Oregon 11; in California 30. The southeastern, southern and southwestern states seemed to have escaped, as only a few scattering cases were reported. The disease first made its appearance in Napa County the latter part of September and continued until the middle of October, claiming in Napa alone five patients, all of whom died. The disease met with at Napa was of a very virulent and rapid form, being of three distinct types: lethargic encephalitis, poliencephalitis and a milder type of encephalitis with a crisis and a rather rapid convalescence.

Age and Sex—There were five cases in all, the youngest patient being five years old and the oldest eighteen; two males and three females.

Relation to Influenza—This relation was direct; in all cases there was a history of influenza.

Mode of Onset—The premonitory symptoms were lassitude, general malaise, marked constipation, insomnia, pain in neck, jerking and twitching being frequent symptoms, with headache and gastro-intestinal disturbances culminating in vomiting.

Fever—All patients had fever, the temperature rapidly rising from normal to 105, with a slight drop before death.

Pulse—The pulse presented the usual features of infectious diseases, ranging from 100 to 120. At times the pulse was very weak and stimulation had to be resorted to.

Central Nervous System—Restlessness and insomnia were marked in all cases, especially the lethargic type which later developed listlessness, stupor, and a mask-like face. There were also present ptosis, diplopia, facial palsy, and partial opisthotonos with a characteristic pill-rolling posture of the hands. The patients remained in the state of lethargy and somnolence with a gradual darkening of the sensorium until pulmonary oedema caused death.

Cranial Nerves—Involvement of the third cranial nerve was shown by diplopia, also by ptosis which was present in three out of five cases. Involvement of fourth cranial nerve was shown by paralysis in three cases. Involvement of fifth cranial nerve was shown by difficulty in mastication in four cases. Involvement of the seventh cranial nerve was shown by incomplete facial palsy

in four out of five cases. Involvement of the ninth cranial nerve was shown by disphagia in four out of five cases.

Peripheral Nerves—Involvement of the peripheral nerves was marked by pain, especially in the occipital region and in the nerves radiating from the spine. The patients also complained of pain along the various peripheral nerves in the upper and lower extremities. This pain at first was of a lancinating nature.

Trophic and Vasomotor Disturbances—There was always more or less cyanosis around the patient's finger tips and toes with profuse perspiration.

CASE REPORTS

History of Case 1—The patient was a well nourished male thirteen years of age, a native of California. He had a moderately severe attack of influenza in 1918. The present illness began October 2, 1922, when he complained of headache, general malaise, and marked constipation. On this day he vomited. His temperature was 102. He was rather talkative with marked insomnia. October 4 patient complained of headache, temperature 102.2. Physical examination was negative. In the evening the headache was more severe. The pupils were moderately dilated, reacting sluggishly to light. The patient was restless, irritable, and slightly delirious. The patellar reflexes were diminished. Kernig's sign was positive on left side; Babinski reaction was negative. The leucocytic count was 12,000. Temperature was 103; pulse, 112. October 5 the patient was restless with twitching of muscles, and was delirious throughout the night; temperature was 104; pulse 120; a marked stiffness of the neck with partial opisthotonos; diplopia present; ptosis and Kernig's sign marked on left, doubtful on right. Examination of chest was negative. Deep abdominal reflexes lost. In the evening his face assumed the expressionless type; at 5:30 p. m. his temperature arose to 105.2 with involuntary urination. October 6 Cheyne-Stokes' respiration during the night. Stupor manifest, but could be aroused to swallow nourishment; condition remained the same during the day, temperature slowly dropping; at 12 p. m. it was 101.8. October 7 dysphagia first noticed; other conditions the same. At 1:15 the temperature was slightly elevated; pulmonary oedema was marked; died at 2:25 p. m. (No autopsy was performed.)

History of Case 2—A well nourished female, aged 18, native of California, attended school, definite history of influenza in 1918. The family history was similar to that of "Case 1." Previous history: Had always been a very nervous girl subject to severe headaches and uterine pains at menstrual periods.

Present Illness—Patient has had a headache and uterine pains for the last three or four days; because she was in the menstrual period the pain was attributed to that. In the afternoon of October 9 she first learned of the death of her nephew, "Case 1," and had an hysterical laughing attack. Shortly afterwards her physician was called. Temperature 102; pupils wide and dilated, not reacting to light; complained of severe headache and pain in back and neck. October 10 temperature throughout the night varied between 102 and 102.4; marked constipation with insomnia. Examination of chest and abdomen, negative. Patellar reflexes normal; Kernig's and Bakinski reactions negative. In the evening pain extended down the spine and was of a lanscinating nature. Pupils as above; temperature rose to 103.4. October 11 pain extending down into legs; temperature 103; pulse 120; well marked double Kernig; Babinski negative; could not move the left leg; paralysis of a flaccid nature. Patellar reflexes absent on left, present on right; no ankle clonus. Plantar reflexes diminished on both sides. Kernig's sign present on both sides; neck stiff and painful. Leucocytes 9000. October 12 during the night the temperature dropped to 99, then rose to 103 and dropped to 103 and dropped again to 100; marked muscular twitching wtih loss of deep abdominal reflexes; some retraction of head; very little pain; patient hopeful with a feeling of well-being. Her pupils remained as above; urinary retention. At 12 o'clock Cheyne-Stokes' respiration with marked cyanosis of face and neck. At 3:40 p. m. spinal puncture was done. Fluid was crystal clear and under no pressure. The cell count showed 80 large mononuclear cells; Globulin, negative; mastic and guinea pig inoculation. The left arm developed a flaccid paralysis with beginning paralysis of respiratory muscles; diaphragmatic breathing with slight opisthotonous; temperature 100; pulse rapid and weak; respiration, difficult; difficulty in swallowing. October 13 temperature still dropping; respiratory rate increasing; dysphagia with retention of urine; commencement of pulmonary oedema; profuse prespiration; mind clear and alert throughout illness; slowly sinking from respiratory paralysis; increasing pulmonary oedema; and death at 6 p. m.

Autopsy Report—Well built, well nourished female; age 18; pupils moderately dilated and equal; beginning rigor mortis of upper extremities. Brain: Marked infiltration and congestion of the vessels in the meninges; marked congestion of cortex and medulla showing a hyperaemia and a moderate exudate, particularly in the region of pons and medulla. Cut section of the brain showed marked punctate hemorrhages below the level of the fourth ventricle especially around the nuclei and extending out into the cortical portion of the brain. See Plate 3. Microscopical section of cerebellum showed perivascular infiltration.

Spinal Cord—Microscopical section of cord showed infiltration along the vessels parallel to the right dorsal horn of cord. Marked inflammation and round-celled infiltration were present about the vessels of the ventral fissure, also inflammation and round-celled infiltration about the vessels of the apex of the left ventral horn.

History of Case 3—A poorly nourished male aged ten, native of California, had a moderately severe attack of influenza in 1918. Present illness began October 3; complained of headache, general malaise, marked constipation with insomnia. October 4: Pulse 160; temperature 105.2; pulse rapid and weak. Patient restless, acts as if in pain, turning constantly with profuse sweating; unable to swallow; involuntary urine with ptosis, diplopia; face assuming mask-like character with arms in partial flexion and the fingers of the hand in characteristic pill-rolling posture. October 5: Patient complained of pain in head when roused from stupor, gradually growing into a more stuporous condition; difficulty in respiration; temperature the same; pulse 120, weak and thready. October 6: Patient in stuporous condition from which it was difficult to arouse him; commencing pulmonary oedema and death at 5 a. m. No autopsy.

History of Case 4—Poorly nourished male aged eight, native of California, attending school, direct history of influenza, brother of "Case 1." Present illness began October 4 with general malaise, marked constipation, talkative, with insomnia. October 5: pulse rapid, temperature 104.2; patient restless, complaining of pain in back of head in occipital region, neck muscles rather stiff and rigid. October 6: Patient very restless, temperature rising, with profuse sweating; difficulty in swallowing, involuntary urine with ptosis and diplopia; face assuming a mask-like character with arms and forearms as in "Case 3." October 7: Child growing into a more stuporous condition; difficulty in respiration; pulse 118, weak and thready. October 8: Patient in stu-

porous condition from which it was difficult to arouse him; commencing pulmonary oedema followed by death.

Autopsy Report—Poorly nourished male. Pupils moderately dilated and equal; marked cyanosis of face and neck. Beginning post-mortem rigidity. Post-mortem lividity from shoulders to buttocks. Brain: There was a marked infiltration of the vessels of the meninges with hyperaemia of the cortical vessels and a grayish exudate in the region of pons medulla. Cut section of the brain showed many punctate hemorrhages, especially around the substantia nigra. The cord, normal. Lungs, pulmonary oedema. Heart, cloudy swelling. Kidneys, cloudy swelling. Spleen, cloudy swelling. Liver, cloudy swelling.

Laboratory Findings of "Case 4"—Spinal puncture done on this case; fluid crystal clear; cell count 3; globulin negative; collodial gold, negative; mastic, negative; Guinea pig inoculation, negative. "Case No. 2" and "Case No. 4" had cultures taken from the ventricles of the brain and heart and inoculated on blood serum, bouillon and slant Agar, with negative findings.

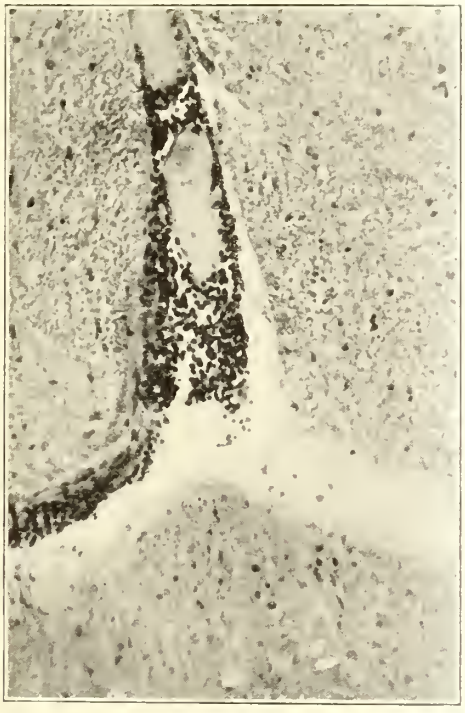

PLATE 2
Inflammation about vessel in brain. Obj. A (Zeiss) Oc.

History of Case 5—Poorly nourished female aged five, native of California, direct history of influenza. Present illness began October 4; died October 8. This case began with general malaise, headache, marked constipation, rapid rise in temperature with rapid, weak, thready pulse; developing stiffness in muscles of neck, diplopia, ptosis, irritability, stupor, delirium, mask-like face, pulmonary oedema, and death.

History of Case 6—Male, aged twelve, native of California; family history negative. Previous history, measles, mumps, scarlet fever. Present illness, September 25, patient had some fever, causing the mother to suspect a gastrointestinal upset. The following day he went to school, complaining of headache and fever; pain over the cervical and upper thoracic vertebra. Physical examination: Fairly well-nourished boy of twelve; restless, constantly moving hands and feet. Eyes showed converging strabismus. Nasal passages, negative. Chest, negative. Abdomen, negative. Upper and lower extremities, negative. Skin dry and warm. Reflexes: Eyes react normally; knee-jerks exaggerated; Kernig sign positive; Babinski reaction positive; slight ankle clonus; cremasterics slightly increased; temperature 102.5; pulse 110; respiration 24.

September 26, some retraction of head but no definite opisthotonos, pain in neck and spine increasing. Spinal puncture taken and fluid crystal clear under slight pressure. Cell count, 18. September 22, spinal puncture seemed to have relieved patient, who was greatly improved; temperature had fallen to normal; respiration 18; pulse 100. The nervousness was replaced by apathy. There was no diplopia noted throughout illness. The reflexes were markedly diminished. There were no sensory disturbances except along the spine, which was markedly hypersensitive. The forearms were flexed across the chest, and attempts at forcible extension were very painful. For the following forty-eight hours there was no change. The patient slept most of the time, after which the drowsiness began to diminish and he made a rapid convalescence. A week later, patient was convalescing satisfactorily. There was no evidence of paralysis; reflexes negative; forearms could be extended nearly 90 degrees; mentally clear.

PLATE 3
Showing punctate hemorrhage and dilatation of vessels throughout the gray and white matter below the level of the third ventricle.

Epidemic Encephalitis belongs to the class of infectious diseases of an inflammatory nature. Rosenau has demonstrated that the filterable virus reproduces the disease in white rabbits. The six cases presented in this paper show three distinct types: Cases 1, 3, 4 and 5 are distinctly lethargic in nature and of a very rapid, virulent form. Case 2 falls in the Poliencephalitis type, while Case 6 is of a milder lethargic type, progressing

after the acute symptoms to a successful convalescence and to a recovery. Most authors claim no contagion or infection; however, here we see a whole family dying, one child after another. Case 1 attended the same school as Cases 3, 4, 5 and 6. Case 2 was the aunt of Case 1, and had been indirectly exposed to Case 1. Therefore, the question of the mode of transmission appears to be rather direct in this family. For the differential diagnoses from the laboratory standpoint, see the following table:

Condition	Color	Globulin	Cells	Lange	Mastic
Normal	Clear	Negative	1 to 5	Negative	Negative
Encephalitis	"	"	10 to 20	"	"
Meningococcus	Turbid	Positive	50 to 800	Meningitic zone	Positive
Ant Poliomyelitis	Opalescent	"	10 to 100	Luetic zone	"

Pathology—The cerebral cortex was found normal except for congestion of the vessels of the meninges (See Plate 1). In the brain substance the changes were more marked in the basilar neuclei of the brain, the upper part of the pons and peduncles and in the gray matter around the floor of the fourth ventricle (See Plates 3, 4 and 5). Negative findings in the cord except in Case 1, where the cord was more or less involved during its entire length. The meninges showed hyperaemia, distention of the vessels with small punctate hemorrhages.

Microscopic—The pia of the cerebrum and cerebellum showed distention of the vessels with blood, round-celled infiltration especially marked around and in the vessel walls. Very slight perivascular infiltration in the brain substance; here and there a hemorrhage is seen in the outer vessels of the cortex. In the medulla, pons, basal ganglion. The pia showed the same pathology, but more marked and the perivascular infiltration follows the vessels deeply into the tissue; cellular infiltration is found both in the white and gray matter but by far the greater per cent is in the gray matter. The cells are mostly lymphocytes, plasma cells, and a few large mononuclear cells. The blood-vessels, though densely infiltrated, showed no endarthritis.

CONCLUSIONS

The pathological pictures showed typical round-celled infiltration with perivascular inflammation, Case 2 showing a marked similarity to poliomyelitis, but such extensive infiltration of the meninges and larger vessels of brain would be unusual in poliomyelitis. A direct relation between influenza and encephalitis was proved in all cases except in that of Case 6. Cases 1, 2, 3, 4 and 5 would rather lead us to suspect that encephalitis is an infectious disease.

I wish to thank doctors E. Z. Hennessey, Robert Crees and C. H. Bulson of Napa for the case histories of these patients; Dr. A. C. Matthews, Medical Superintendent of the Napa State Hospital, for allowing me the time to do this work; and Dr. Frank E. Blaisdell, Sr., and Dr. William Ophuls of the Stanford Medical Department for taking the photographs and for their suggestions.

CHAIRMAN'S ADDRESS, EYE, EAR, NOSE AND THROAT SECTION *

By F. A. BURTON, M. D., San Diego

First of all I wish to thank Dr. Harvard McNaught, the secretary, and the members of the section who have co-operated in providing the program for the meeting. With this valuable assistance, the work of the chairman has been a pleasant task. Since our time is limited, I will confine myself to a few general remarks.

There are three classes of eye, ear, nose and throat specialists—the progressive, the stationary and the retrogressive. The retrogressive has passed the period of usefulness; the stationary is the one who says in his heart, "My work is good enough"; the progressive is the specialist who forges ahead. It is not necessary that one go forward by leaps and bounds, but the essential point is that he is moving in the right direction.

It is a well known fact that every religious, political or educational system is judged by the kind of man it forms. This also holds true of a medical society—with this difference: that the latter is more democratic. As the people of a democratic government are the government, so the members of a medical society are the society, and it is up to the individual member to decide the nature and value of his organization. We get out of life just what we put into it, and you will get out of this section meeting just what you put into it. If you are satisfied to listen to the reading and discussion of papers by others, you will get something out of the meeting, but you will get infinitely more if you take part.

In his practice the specialist of the first class makes careful, thorough histories; he goes back at least to the history of the immediate family, and the patient's history of disease is taken from birth to the time of examination. Wherever possible, it is valuable to obtain the information of when, where and how the first symptom relevant to the disease in question made its appearance. It is not enough to learn only the symptoms presenting at the time of the examination.

The progressive eye, ear, nose and throat specialist continually reviews the anatomy of his field. This is especially needful in investigating the nasal accessory sinuses, because of their anatomical variance. In addition to the usual methods, transillumination and the X-ray are employed. The X-ray may not be necessary to determine a sinus infection, but it is valuable in ascertaining the size, shape and extent of the cells. No sinus surgery should be performed without first determining these important points. The progressive specialist in this field looks for pathology. It is not scientific, upon hearing the symptoms, to jump at a final conclusion as to the diagnosis. In determining the pathology causing the symptoms, a complete physical examination is often required, as it is important that the most urgent thing receive attention first. In case of infection, it is of

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

undoubted value to know the bacteriology. If due to streptococci, the condition is more serious than if due to staphlococci, and if the intruding germ be the streptococcus haemolyticus, rapidity of action and probability of extension must be taken into account. And if the infecting organism be the streptococcus mucosus capsulatus, one looks for extensive destruction of both soft and bony tissue, even in the absence of pain.

The progressive specialist, in his surgical cases, gives careful attention to the matter of anaesthesia. He considers the welfare of the patient and is not a slave to routine. In his intranasal and sinus surgery, whenever possible, he uses local anaesthesia.

The specialist of the first class avoids unnecessary surgery through conservative medical treatment; where surgery is necessary, through thorough examination and pre-operative care, he lowers the surgical risk. He provides wherever feasible a field free from pus and inflammation. Subsequent to the operation he administers the indicated post-operative care until the wound is healed. In this way he observes the final outcome of his work, renders a valuable service to his patient, and adds to his own satisfaction. The specialist who is moving in the right direction, has the welfare of his patient, his society, and his fellow physician sincerely at heart.

You share in the responsibility of failure on the part of your medical society, your hospital, or your fellow in medicine to comply with the highest requirements. Such a failure calls for calm and constructive criticism. Boost, don't knock. You cannot despise, envy or hate another without giving him some of your time. Be leaders, not followers. A man is not made by what others think of him, but by what he thinks himself. Merit a good opinion of yourself.

He who has climbed can lift, and you have reached an enviable height among eye, ear, nose and throat specialists. Others are influenced by what you do. You have accepted the exalted position of leadership. Let your relations with patients be free from mystery, and with referring physicians, free from secrecy. Your patient has the inalienable right to human interest and scientific service.

Remember with Lord Essex: "Genius is entitled to respect only when it promotes the peace and improves the happiness of mankind."

Resolution Approving Women's Auxiliary.—"The Women's Auxiliary of the State Medical Association of Texas respectfully requests the approval of the American Medical Association of a movement to organize a Women's Auxiliary to the American Medical Association. The object of this auxiliary shall be: To extend the aims of the medical profession through the wives of the doctors to the various women's organizations, which look to the advancement in health and education; also to assist in entertainment at all Medical Conventions, and to promote acquaintanceship among doctors' families that closer professional fellowship may exist."—Abstract from Minutes of the Seventy-Third Annual Session of the A. M. A.

CHAIRMAN'S ADDRESS, SURGICAL SECTION *

By CHAS. D. LOCKWOOD, A. B., M. D., F. A. C. S.

Members of the Surgical Section:—

I am deeply appreciative of the honor you conferred upon me one year ago in electing me chairman of this section. Although this is but the third year that we have met as an independent section, there is already apparent a spirit of loyalty and co-operation which augurs well for the future growth and scientific character of our meetings.

The field of the general surgeon is being ever more and more narrowed by the growth of specialism. Surgeons of the generation that is now passing have regarded as their domain the entire field of surgery, with the possible exception of eye, ear, nose and throat work. The surgical specialists have gradually emerged as our knowledge of technique and diagnosis broadened. The older specialists were the natural outgrowth of their environment and practice. Well grounded in the principles of surgery, they readily acquired the technique of new operations and kept abreast of all new developments in surgery. Chance, special adaptation or the exigencies of practice were the deciding factors in the selection of a specialty more often than deliberate choice.

This older type of specialism was founded upon a broader surgical experience and a deeper knowledge of human nature, but it lacked in the diagnostic skill and refinement of technique which characterize the specialists of today. The newer generation of specialists have, for the most part, deliberately chosen their field of work and have acquired great skill in the use of the newer instruments of precision and familiarity with the laboratory and other methods of diagnosis. Too often this special skill has been acquired at the sacrifice of a broader and more fundamental knowledge based upon practical experience.

It is no longer possible for any one individual to cover the whole field of medicine and surgery and it is inevitable that specialism will flourish ever more and more. There is, however, grave danger that this tendency toward specialism will lead to professional suicide. Regular schools of medicine have become so highly specialized and exclusive that they no longer qualify men for general practice. The vast majority of recent graduates are ambitious to become specialists and few of them are willing to travel the more difficult path of the general practitioner. Our line of communication or contact with the average sick person is being broken and the place of the old-fashioned family physician is being usurped to a certain extent by the chiropractors, the osteopaths and other cultists.

Many people cannot afford to pay specialists' fees and they are unwilling to do so when they have only what they believe to be simple ailments. There should be some way provided whereby the best in medicine and surgery will be avail-

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

able for the average citizen. This need is being met in a fairly satisfactory way for the poor man by free clinics and dispensaries, but it is more difficult for the self-respecting person of moderate means to secure the best that scientific medicine has to offer. This large class patronizes extensively the faddist and the pseudo-doctor of the day. It is to this class that we must look for support in our efforts to promote public health. They must have more of the benefits of scientific medicine than they can afford to pay for at current fees of hospitals, laboratories and specialists. There are two or three possible solutions of this problem.

The organization by physicians of health centers, accessible to citizens, country districts and smaller towns. These centers must be under the control of the medical profession, either through their county societies or by other means of co-operation between medical men. They should be manned by a corps of physicians representing the various specialties, nurses trained in public health work and technicians in laboratory and X-ray work. Patients too sick to visit these centers should be cared for in community hospitals, conveniently located and under the direction of the personnel of the health center. Contact should be maintained with convalescent patients and those only mildly sick through visiting nurses and younger physicians who are serving an apprenticeship before entering upon a specialty. A schedule of fees commensurate with the ability of the patient to pay should be maintained and a fair distribution of this compensation made among those serving the center.

Group clinics, organized by physicians and conducted as private enterprises. The fundamental object in every such organization must be better service to the sick. Co-operation is most essential in dignostic work. Not only is proximity of offices desirable, but there must be congeniality, mutual respect and a high sense of responsibility on the part of each member of the group. There should be perfect freedom in referring patients to the various departments and frequent group conferences should be held on obscure and difficult cases.

The aids to diagnosis have become so numerous and complex that little or no profit can be expected to accrue from the diagnostic side of medicine. It is possible, however, to greatly reduce the cost of complete examinations by co-ordinated effort and to bring it within the reach of those of average incomes.

The third method by which complete and satisfactory medical and surgical service may be rendered is through a well organized hospital having a closed staff. If it is to serve all classes of patients and give them the benefit of group diagnosis, it must have a large endowment and a resident staff. Such institutions are possible only in our larger cities or connected with teaching institutions.

What shall be the role of the general surgeon in this new era of medicine which seems to be dawning? Is his field to become so restricted by the encroachments of the various specialists that he himself will be compelled to limit himself to one organ or one group of organs? Is he to share equally with the internist the growing field of diagnosis or is he to degenerate into a repair man who will be called in to patch a blowout or remove a defective spark plug?

The field of diagnosis has heretofore been surrendered largely to the internist and the surgeon has been content to concentrate upon technique. There is no good reason why this should be so. The qualities of mind and the manual dexterity which distinguish the modern surgeon also qualify him for the work of a diagnostician. With a broad general training, his special knowledge of anatomy and his familiarity with living pathology, he should be ideally equipped to compete with the physician in the field of diagnosis. There should be no line of demarcation between surgical diagnosis and general diagnosis.

The physician and the general surgeon aided by the laboratory and other special diagnostic facilities, should work hand in hand maintaining a broad outlook upon the whole field of medicine and acting as balance wheels for the more restricted specialties.

Educating the People—"To give the people such a general knowledge of medicine that they will appreciate the importance of methods for the prevention of disease, will appreciate the advantages of early diagnosis and treatment of beginning maladies, and know something of the nature of the diseases with which they are or are likely to be afflicted, but particularly that they will be less credulous in accepting the claims of uneducated and untrained dabblers at the healing art, is an undertaking of no small magnitude. One naturally wonders how it is to be accomplished and who is to accomplish it. That the medical profession, the nursing profession, and the Public Health Service are now rather promiscuously engaged in the undertaking does not assure us that it will be accomplished by either or all of them.

When the family physician was in vogue, his people entrusted the care of their health and their lives to one in whom they had confidence, whose word they accepted without question, whose advice they followed without reservation. They had no desire for intimate knowledge of disease processes and saw no occasion to investigate the relative value of different methods of treatment. There are still a few of these people in the world. There were many others not thus attached; some with a little wisdom, more conceit and no confidence in anyone; some with no wisdom, no conceit and confidence in everyone; but all complaisant dupes to the ingenious tyro, smooth-tongued charlatan, and patent medicine venders. There are still many of these people in the world. Men in the medical profession bewail the credulity of the people in things medical, but of all the people in the world the most credulous in things not medical are the men in the medical profession."—(The Journal of the Kansas Medical Society, June, 1922.)

Resolution Directing a Survey of Pay Clinics and Group Practice—(Abstract from Minutes of the Seventy-Third Annual Session of the A. M. A.)

"(d) Your committee approves the recommendations of the Board of Trustees that a survey be made of existing pay clinics, diagnostic clinics and group practice, to be conducted jointly by the Judicial Council and the Council on Medical Education and Hospitals. We recommend that their reports and recommendations be submitted to the next annual meeting of the house."

AN ANATOMICAL AND EMBRYOLOGICAL STUDY OF THE PERINEUM *

By MILEY B. WESSON, M. D., San Francisco

INTRODUCTION

The foundation of all perineal surgery is an exact knowledge of the rectourethralis muscle and Devonvilliers fascia. The information gained from a perusal of the literature is unsatisfactory, as the nomenclature is confusing, and the descriptions vary markedly, being based upon studies of individual variations. The exact origin and insertion of the rectourethralis muscle is most important, since, aside from the loss of urinary control caused by cutting the external vesical sphincter, the only valid objection urged against the perineal prostatectomy is the danger of a rectal tear due to the improper dividing of this muscle. Devonvilliers fascia is the goal aimed for in every perineal operation, and when its glistening white layer comes into view the surgeon feels that he has passed the region of uncharted dangers. This fascia, which separates the rectum from the prostate, can be split into two layers, and hence the didactic statement, that it represents the fused layer of the fetal peritoneum, has been generally accepted.

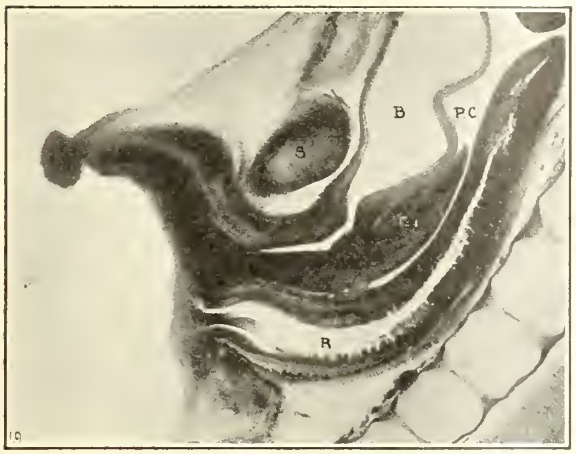

Fig 1.—Mid-sagittal section of genito-urinary region of 46 mm. human embryo. The fused layers of fetal peritoneum have not been wholly absorbed, as is shown by the presence of small "cysts"; S, symphysis; B, bladder; PC, peritoneal cavity; ED, ejaculatory duct; R, rectum. (Embryo, Carnegie Institute, 1686, slide 23, row 1, section 2.) X 21.

HISTORY

Devonvilliers, in 1836, enunciated the hypothesis that the center or nucleus of the perineum is a prerectal raphe or "aponeurosis prostato-perintonele." This fibrous plane is triangular in shape with a truncated apex deep behind which blends with the superior layer of the triangular ligament, while the base at the top is adherent to the inferior face of the peritoneum, thereby helping form the recto-vesical cul-de-sac. The posterior layer is in contact with the rectum to which it is joined with very loose cellular tissue, while from the superior face arise dense cellular elongations which envelop the seminal vesicles, vasa-deferentia and inferior extremities of the ureters.

In 1899 Cuneo and Veau went a step further and stated that the prostato-peritonele aponeurosis of Devonvilliers was formed by a fusion of the fetal peritoneum of the rectovesical cul-de-sac, the two peritoneal layers combining and forming an aponeuotic sheet with a complete correspondence of the arrangement of the peritoneum in embryos of both sexes. Even if the original fused layers disappear they make the framework for later layers of fibers. As proof of this primitive fusion they call attention to evidences of incomplete fusions such as vesico-seminal cysts, perineal hernias and the cul-de-sac of Douglas in the female.

The following year Proust stated that, while the ideal scheme was to admit the existence of a prerectal fascia forming a nucleus of the perineum, as suggested by Devonvilliers, unfortunately the hypothesis could not be reconciled with surgical anatomy, for while it was easy to separate the coverings of the prostate into anterior and posterior layers, it was most difficult to peel out the seminal vesicles, bladder and rectum.

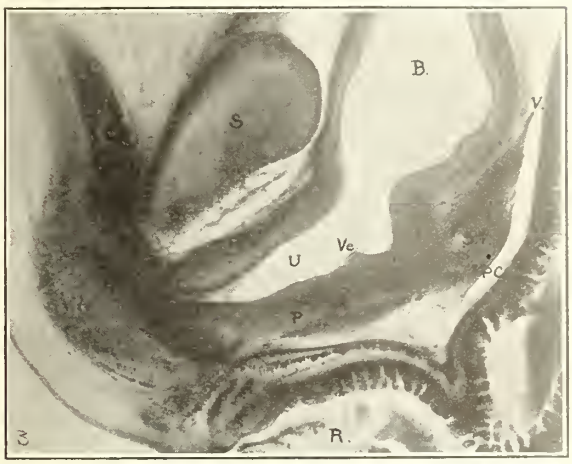

Fig. 2.—Sagittal section through pelvis of 67 mm. human embryo: B, bladder; U, urethra; Ve, verumontanum; V, vas deferens; SV, seminal vesicle; P, prostate; PC, peritoneal cavity; R, rectum; RU, rectourethralis muscle; CC, corpus cavernosus; S, symphysis pubis. (Embryo, Carnegie Institute, 1656, slide 47.) X 18.5.

MATERIAL AND METHODS

The material used for microscopic study consisted of serial sections of 31 human embryos obtained from the collection of the Carnegie Institute of Embryology. Several specimens of the rectourethralis muscle were obtained at operation, sectioned and stained with differential stains. The microscopic investigations consisted of dissections of both preserved and fresh cadavers of infants and adults. A glass model was constructed of the pelvis of a seven months fetus, cut transversely in sections 100 microns thick. An Edinger projection apparatus was used, and the sections traced directly on 8x10" glass plates by means of various colored Higgins inks. Distortion of the model was prevented by keeping the magnification in proportion to the thickness of the sections. The glass plates were then stacked, divided into packs about two inches thick and bound firmly with adhesive plaster. When mounted in a frame, with electric lights behind them, they appeared as colored gela-

* Read before the Section on Urology at the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

tin molds in a glass case. A preparation of this kind is far superior to a wax model for perineal studies, as it gives a transparent presentation of an entire region, which in this model shows ten structures and their relationships, instead of an opaque representation of a single organ.

EMBRYOLOGY OF THE PERINEUM

The primitive pelvis is divided into a ventral and dorsal half by the fusion of the two urogenital folds which unite throughout their whole length in the median line. This frontal partition is termed the genital cord and appears in embryos between 19.4 and 20 mm. It was formerly believed that sexual differences appeared with the formation of the genital cord, but Spaulding has recently shown that they are present from the be-

Fig. 3.—Transverse section through posterior urethra, distal to verumontanum, of 210 mm. human embryo. A dense fascia surrounds the utricle and ejaculatory ducts, separating them from the prostatic tissue: U, urethra; Ut, utricle; ED ejaculatory duct; P, prostate; PC, peritoneal cavity; D, Denonvillier's fascia. (Embryo, Carnegie Institute, 2402, slide 245, section 2.) X 18.5.

ginning. The rectovesical pouch which extends to the floor of the perineum in a 15.5 embryo reaches just below the level of the verumontum in a 46 mm. specimen (Fig. 1), and at 240 mm. reaches to the middle of the seminal vesicles. In many of the specimens studied the peritoneal pouch was asymmetrical, being slightly deeper on one side than the other.

When the peritoneal layers fuse, the mesothelium is absorbed and disappears, leaving only a bed of mesenchyme. In one 25 mm. embryo there was an apparent raphe as the absorption was not complete; in other specimens showing incomplete absorption the line of fusion was marked by isolated portions simulating cysts—all lying closer to the rectum than to the prostate. In none of the older specimens, where differentiation is more complete, is there any evidence of the persistence of the fused peritoneal layers as a raphe or cysts (Fig. 2).

GROSS ANATOMY OF PELVIC FASCIA

Because of the confused nomenclature, a brief description of the gross anatomy of the pelvic fascia is necessary. This layer is a continuation of the transversalis fascia in front and the iliac fascia on the sides. It is made up of a primary parietal layer and a secondary visceral layer. The parietal layer forms a cylindrical membrane attached above and below to the inlet and outlet of the pelvis, forming the pyriformis fascia behind, the posterior layer of the triangular ligament in front, and laterally the obturator fascia and ischiorectal fascia (or covering of the under surface of the levator ani muscle).

The visceral pelvic fascia is a membranous diaphragm separating the pelvic cavity above from the perineum below and covering the upper surface of the levator ani muscle. This fascia passing inward from the white line on either side forms the lateral ligaments of the bladder, and at the junction of the bladder and prostate it splits into two layers, one passing up around the bladder and the other down over the prostate. The former splits into two layers on either side of the midline to enclose each seminal vesicle and vas deferens, and then bending together continue forward over the bladder to the pubes forming the anterior true ligaments. From that portion of the fascia overlying the seminal vesicles and vasa deferentia arises the layer that forms the outer coat of the ejaculatory ducts and accompanies them through the prostate (Fig. 3).

The prostate has a capsule which consists of a comparatively thin layer of fibrous tissue and involuntary muscle fibers closely adherent to the gland and penetrating the substance. Being continuous with the glandular stroma, it cannot be separated from it without laceration of the gland tissue. It is analogous to the fibrous capsules of the liver and spleen.

The layer of fascia which passes down around the prostate forms a funnel-shaped sheath which is complete except for a vertical band on the anterior surface. Here, because of the extra strain placed on the pelvic floor, due to the upright posture of man, there has been a condensation of fascia and fibrous prolongations between sheath and capsule which unite them so firmly that it is impossible to separate them.

Devonvilliers fascia or the fascia between the prostate and the rectum consists of two layers, one covering the prostate and the other the rectum. These two layers meet above at the vesico-prostatic junction, where they both spring from that portion of the visceral fascia which may be said to stretch across the pelvis between the urogenital apparatus and the rectum. When the rectourethralis muscle is divided the incision should likewise divide the posterior or rectal layer of Devonvilliers fascia,

which is then pushed back with the rectum. Thus is formed the "espace decollable rectroprostatique" or separable space, and the anterior layer of Devonvilliers fascia or sheath of the prostate is exposed. The texture of this resistent membranous layer resembles the dartos, being made up of glistening fibrils most pronounced in the midline.

GROSS ANATOMY OF THE RECTOURETHRALIS MUSCLE

The rectourethralis muscle is of primary importance to the perineal surgeon since it is responsible for the acute anterior flexure of the rectum and the consequent approximation to the apex of the prostate (Fig. 4). A bundle of muscle fibers is sent to the coccyx from the posterior thickened longitudinal band of the rectum, thus forming the recto-coccygeus muscle; and a corresponding bundle arises anteriorly at the level of the verumontanum

Fig. 4.—Transverse section through pelvis of 208 mm. human embryo, showing the relationship between the rectourethralis and levator ani muscles: RU, rectourethralis muscle; LA, levator ani muscle; OI, obturator internus muscle; I, ilium. (Embryo, Carnegie Institute, 2402, slide 261, section 1.) X 7.

and passes to the raphe of the external vesical sphincter, thereby forming the rectourethralis muscle (Fig. 5). This raphe fuses with the under side of the central tendon of the perineum, which lies about 2½ cm. in front of the anus and is formed by an interdigitation of the fibers of the external anal sphincter, the transverse perineal and the bulbocavernosus muscles.

A study of the specimens of the rectourethralis muscle obtained at operation showed smooth muscle fibers at one end flowing into a bed of elastic tissue containing striated fibers at the other.

Contrary to the generally accepted view the levator ani muscle lies lateral to the prostate and is definitely separated from it, and sends no fibers over its posterior surface either directly or indirectly through the rectourethralis.

DISCUSSION

The fascia being merely condensations of connective tissue, have marked individual variations in density. From the urological standpoint they are of interest not only as structural supports, but as protective partitions which guide the paths of extravasations of urine, infections and malignant growths. The perineum has a three-fold protection from extravasation of urine due to rupture of the anterior urethra, the first barrier being Bucks fascia, then Colles and lastly (the anterior layer of) Devonvilliers fascia. The latter is of primary importance in preventing cancer of the rectum spreading anteriorly and effectively confines early cancer of the prostate so that it can be entirely eradicated by means of the radical prostatectomy of Young.

Two anomalies of interest to the urologist were

Fig. 5.—Sagittal section through pelvis of adult, showing diagramatically the relation existing between the external vesical sphincter (EVS) and the rectourethralis muscle (RU); if the dissection follows the posterior surface of this muscle the rectum will be opened, but if the muscle is cut at its junction with the external vesical sphincter the rectum will drop back and the prostate be exposed.

seen in the embryos studies. In the glass model of Embryo 2375 the testicles show in the inguinal canals, the right one being normal, but the left is rotated so that the globus minor lies above and the globus major below. Could not this be the forerunner of a torsion of the testicle?

Embryo 1656 has a long Cowpers duct, whose orifice is near the meatus. This is of particular interest since no adequate theory has yet been advanced to explain the origin of periurethral ducts. In an adult such a structure would undoubtedly be classified as such.

SUMMARY

1. Devonvilliers fascia is not formed by a fusion of the fetal pelvic peritoneal.

2. The rectum, at the level of the prostate, is surrounded by a more or less definite cuff of

connective tissue in which the lowest part of the peritoneal cavity dips.

3. At no stage of development is the peritoneum in contact with the prostate, it always being nearer to the rectum than to the prostate.

4. The recto-prostatic space is filled at first with a synticium or mass of embryonic connective tissue cells; eventually differentiation occurs and there is a condensation of connective tissue anteriorly and posteriorly. The anterior layer covering the prostate is the thicker and the elastic tissue fibrils predominate, thereby causing the shiny appearance characteristic of Devonvilliers fascia.

5. A sheath of fascia surrounds the ejaculatory ducts and utricle as they pass through the prostate.

6. The rectourethralis is a sheet of muscle arising from the external longitudinal layer of the rectum and ending in the raphe of the external vesical sphincter.

7. In exposing the prostate by the perineal route the rectourethralis muscle should be cut close to the central tendon, the incision being sufficiently deep to sever the posterior or rectal layer of Devonvilliers fascia, and the dissection continued anteriorly to the muscle, for if the posterior layer is followed it leads directly into the rectum. If the incision is made anterior to the central tendon the dissection leads first into the venous bulb, causing hemorrhage, and then through the external vesical sphincter. The opening of the rectum is avoided, but there is a prolonged and often permanent loss of vesical sphincter control.

8. Long Cowpers ducts ending near the meatus probably develop as periurethral ducts.

(549 Flood Building.)

Resolution on Medical Ethics—"Solicitation of patients by physicians as individuals, or collectively in groups by whatsoever name these may be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communications, is unprofessional. That does not prohibit ethical institutions from a legitimate advertisement of location, physical surroundings and special class—if any—of patients accommodated. It is equally unprofessional to procure patients by indirection through solicitors or agents of any kind, or by indirect advertisement, or by furnishing or inspiring newspaper or magazine comments concerning cases in which the physician has been or is concerned. All other like self-laudations defy the traditions and lower the tone of any profession, and so are intolerable. The most worthy and effective advertisement possible, even for a young physician, and especially with his brother physician, is the establishment of a well-merited reputation for professional ability and fidelity. This cannot be forced, but must be the outcome of character and conduct. The publication or circulation of ordinary simple business cards, being a matter of personal taste or local custom, and sometimes of convenience, is not per se improper. As implied, it is unprofessional to disregard local customs and offend recognized ideals in publishing or circulating such cards.

"It is unprofessional to promote radical cures; to boast of cures and secret methods of treatment or remedies; to exhibit certificates of skill or of success in the treatment of disease; or to employ any methods to gain the attention of the public for the purpose of obtaining patients."—Abstract from Minutes of the Seventy-Third Annual Session of the A. M. A.

EARLY HOSPITAL HISTORY IN THE UNITED STATES *

By J. B. CUTTER, M. D., Watsonville, Cal.

With universal interest rapidly growing in all parts of the United States, in the upbuilding and expansion of the modern hospital, the following contribution of historical data about hospitals seems timely.

It is probable that the first hospital in the United States was the Pennsylvania Hospital. There were earlier institutions in Canada and Mexico, and efforts were set on foot as early as 1709 to establish a hospital in Philadelphia. In 1730-31 the City Almshouse was founded, and did medical work, but it was not until 1750-51 that the Pennsylvania Hospital had its actual birth. A history of this hospital was published by Dr. Thomas G. Morton in 1895.

A number of physicians and leading citizens of Philadelphia presented a petition on January 23, 1751, to the Provincial Assembly, praying for authority and assistance to establish an institution for the care of "the insane and indigent sick." Dr. Thomas Bond and Benjamin Franklin seem to have been most active in working up public sentiment, and pushing the matter before the Assembly. The hospital was finally granted a charter by the Governor May 11, 1751. Joshua Crosby was the first president of the Board of Managers and Benjamin Franklin, the first clerk.

The charter of the Pennsylvania Hospital, after providing minutely for the government and management of the proposed institution, appropriated the sum of two thousand pounds to be paid in two annual installments, conditioned on the raising of a like amount through private contributions. Two thousand seven hundred fifty pounds were subscribed within a short time, and the hospital was organized.

The Board of Managers then petitioned Thomas and Richard Penn, who were then living in England, to donate a site for the hospital. This request after considerable correspondence was finally granted, but with so many restrictions that the board resolved not to accept the gift. As the need of the hospital was pressing, a temporary arrangement was entered into by which a private house was rented, and opened for patients February 6, 1762.

Negotiations were kept up with the Penns, which finally led to the purchase from them of part of the present site in 1754, and the remainder of the land was given to the hospital in 1767.

A suitable site having been obtained, plans were drawn and approved and the building begun. The cornerstone was laid May 28, 1755, and the building was so far completed by December 17, 1756, that patients were moved into it on that date from the temporary quarters.

In the meantime the first president, Joshua Crosby, died in June, 1755, and was succeeded by

* Read before the Santa Cruz County Medical Society, at its meeting held in Santa Cruz March 6, 1922.

Benjamin Franklin, who served until his appointment as Provincial Agent at London, in 1757.

This is an outline of the early history, as far as authority can be found, of the first hospital in the United States.

The New York Hospital was the second hospital of importance to be established in the United States. Its charter was granted in 1771.

The history of this second hospital is more clear, and its connection with Trinity church adds to its interest.

There is especial appropriateness in the linking of those two ancient New York institutions, for it was in Trinity church that the hospital was conceived, and through the church influence that it came into being. There is spiritual significance in the association of the church with the divinely appointed mission of a hospital at this early period.

Modern medicine finds in the wisdom of ancient Greece its first great exemplars. Hospitals, as we understand the term, did not exist, but the temples of the gods both in Greece and Italy were the refuge of the sick, and there the priests or family of Aesculapius ministered to those ill of body or mind. In full consciousness, as Walter Pater expresses it, of "the religiousness, the refined and sacred happiness of a life spent in the relieving of pain."

Coming down to modern times, we find that light of the early nineteenth century, Walter Moxon, giving expression to much the same thoughts, "sine missione nascimur," we live to a duty, "It (the hospital) is to be to each individual sufferer under our care, all that a man can be to his fellowman in sickness."

In 1123, St. Bartholomew's of London was founded in the same religious spirit, by private funds donated at the solicitation of Prior Rahere. St. Bartholomew's, organized without ecclesiastic connection, naturally commended itself to the colonies in North America. Other early hospitals in England were: St. Gregory's, founded by Archbishop La Franc in 1084; Holy Cross Hospital, Winchester, 1132; St. Mary's, 1197; and St. Thomas', founded by Peter, Bishop of Winchester, in 1215.

In the year 1769, the colony of New York, with a population of 300,000 of whom only 20,000 lived in the city, had not a single hospital. Medical education in the Colonies was almost as backward. In 1767 a modest beginning had been made in New York by the establishment of a medical department in Kings College, now Columbia University. Two years later, in 1769, the graduating exercises of the first recipients of its medical degrees were, by a happy chance, held within the walls of the original Trinity church. A notable assemblage, including the Governor of the colony, Sir Henry Moore, was present. Lasting distinction was given the occasion by Dr. Samuel Bard, a student of Kings College and the London Hospital, a graduate of medicine of Edinborough University, and professor of the practice of medicine in the college, who after addressing the two graduates on the high duties of their profession, eloquently urged on the community the crying need for a general hospital, not only for the care and relief of the sick but also as affording the best and only means of instructing students properly in the practice of medicine.

This moving appeal met with an immediate response, Sir Henry Moore then and there heading a subscription, and many contributions were received. Sir Henry did not live to see his work crowned, but the hospital was organized in 1770, and on June 13, 1771, in the term of his successor, the Earl of Dunmore, a royal charter was granted to "The Society of the Hospital, in the City of New York."

Steps were immediately taken to procure a site. The city offered a tract of three-quarters of an acre near where the present Municipal building stands. Trinity church which, in 1775, had given Kings College its grounds in Park place, offered the hospital a ninety-nine-year lease of a two-acre plot at Canal and Hudson streets. The society decided to buy a five-acre tract of land on an elevated site on the west side of Broadway, opposite Pearl street. Imposing hospital buildings were painstakingly planned and construction was pressed with all convenient speed. A staff of physicians, including Drs. Bard and Jones, was appointed and preparations for the reception of patients were made. But on the 28th of February, 1775, when the building was practically completed, an accidental fire consumed the interior, and, as the New York Gazette and Weekly Mercury described it, "This beautiful and useful structure, at once the pride and ornament of the city, became a ruin." The Governors made a fresh appeal for funds, four thousand pounds was granted by the Colonial Assembly, reconstruction was begun, and within a year the new hospital building was completed.

During the war of the Revolution, the hospital had a stormy career, and passed into the hands of British and Hessian troops, who used the hospital as barracks and occasionally as a military hospital. When the soldiers were withdrawn and the war ended, a tedious period of readjustment ensued, but not until January, 1791, was it that "this asylum for pain and distress," as the Governors feelingly described it, was finally opened for the treatment of patients.

The original structural group, containing about five hundred beds for patients, continued in active use until 1870, when the Governors of the society found the financial burden of maintaining a hospital on that spacious and valuable site too heavy to bear. They accordingly leased the grounds on long terms, vacated the buildings, and a new hospital was built on the present site, where the work of the society's general hospital has since been conducted.

The need for an emergency service in the lower portion of New York City became so acute that what was long known as the "Chambers Street Hospital" was established in 1875. From that date until 1894, when the modern Emergency Hospital was built, 320,000 patients were treated.

The illustrious names of William T. Bull and

Lewis A. Stimson are forever incorporated into the memorable history of this hospital.

The ambulance service was an important part of the work, which all told aggregated the imposing number of 245,000 calls.

The spirit of noble purpose, devoted and altruistic service which moved our ancestors to create and maintain these wonderful first hospitals, has been repeated in many cities of the United States. Will the modern hospital stand on the same high plane of purpose and achievement?

THE CURABILITY OF SYPHILIS *

By VICTOR G. VECKI, M. D., San Francisco

It is due to animal experimentation that we are able to claim that syphilis is a comparatively easily curable disease and able to hope that it may be abolished. All fixed rules, however, and all schedules must be abandoned. A proper diagnosis must be made, but the benefit of any doubt given to the patient. Every fresh case can and must be aborted. The intensity of the treatment is to be regulated by the patient's bodily condition and his tolerance for the remedies.

Minute care in the preparation of the patient, a faultless technic, heeding of any alarm signals and eventual reactions are absolutely necessary in order to finish intensive treatment without damaging the patient. Each subsequent treatment must be more intensive than the preceding one which failed to cure. Neurosyphilis demands slowly increasing doses, especially small first doses whenever vital parts may be involved. So-called parasyphilitic diseases, mainly tabes dorsalis, yield only to long, regular, persistent and proper treatment. The rhythmic, not the desultory, jerky treatment, accomplishes a cure. The intermittent treatment has failed, it must be abondoned and replaced by the continuous treatment, that is, until a cure is realized.

Recent experiences with the use of very small doses of silver-arsphenamin preparations make the use of mercury less and less imperative; it certainly is not very desirable. Kolle's experiments on animals have demonstrated that mercury is active against the spirochetae only in doses that come very near to the fatal ones.

Neosilver-salvarsan is the best arsenic preparation at our disposal, it is easy of solution, very slow to oxidize and is the most parasitotrop and the least organotrop of all antiluetic remedies. We know that silver itself is an antisyphiliticum, its adding to the arsenic has not increased the toxicity, but only the effectiveness of the remedy. The silver molecule activates the salvarsan molecule. The arsenic being the spirillocide, the silver takes the place of the considerably more toxic mercury to make conditions in the tissues unfavorable for the multiplication of the spirochetae.

There is no real evidence whatever of the dangerousness of the silver-salvarsan preparations. Because of neosilver-salvarsan's low toxicity, the total dose in any given case can be reached quicker and safer and therefore the rhythmic, regular and persistent treatment is possible and our prognosis considerably better. Neurorecidives are never seen, intraspinal injections can be abandoned and replaced by draining of the spinal canal immediately after every third or fourth intravenous injection of neosilver-salvarsan.

The neglecting of proper iodide medication is responsible for many failures in the treatment of syphilis. Iodide is very effective when given intravenously.

The colorimetric reaction of Vernes, when once available everywhere, will enable us to reach periodically a quantitative diagnosis and also to judge when a patient really is cured.

We must positively avoid the dangerous condition created by stopping the treatment when almost all spirochetae are destroyed, and thus giving the few surviving clusters more favorable conditions for their pernicious activities. We agree with Vernes when he preaches that one must do too much in order to do enough.

Syphilis could be abolished when the recognizing of it and its effective treatment will be properly understood by the bulk of the profession, when it will not be considered a vice disease, but just a highly contagious one, and when those in power will understand that the proper fighting of this scourge would be by far cheaper than the support of all the hospitals, asylums, orphanages and prisons, populated by syphilitics and their tainted offspring.

(516 Sutter Street.)

* Abstract of a paper on the Curability of Syphilis read by Dr. Vecki at the Fifty-first Annual Meeting of the Medical Society of the State of California, held in Yosemite National Park, May 15 to 18, 1922.

Arizona State Secretary Visitor at Yosemite Meeting—D. F. Harbridge of Phoenix, Arizona, secretary Arizona State Medical Association, was a visitor at the fifty-first annual meeting of the Medical Society of California. Dr. Harbridge read a paper on "Sympathetic Iridiocyclitis—a Case." The author contributes the case history of a patient, who after having the offending eye removed and his oral cavity made sanitary, recovered a vision 6/15 with a —4D. lens. A detailed pathological study by Finoff of the enucleated eye confirmed the clinical diagnosis. The various theories in explanation of the transference of the inflamation from the sympathogenic to the sympathizing eye, the possible relationship to tuberculosis, the very probable influence of an endogenous infection, and the bearing anaphylaxis may offer as a solution of the problem, is discussed.

Goat Gland Hospital for Ensenada—It is reported in the public press that Ensenada is to have a Goat Gland Hospital. The San Diego Cal., Union says: "A corps of surgeons, headed by Dr. Benson of Calexico, has leased the Felix Werbser hotel at Ensenada for 15 years and is converting the building into a hospital. Associated with Dr. Benson, it is said, is one of the foremost surgeons of Kansas City. Hundreds of high class goats are to be shipped from San Diego to Ensenada by boat to furnish glands for patients at the new hospital"!!!

Date of 1923 Session—The Board of Trustees of the American Medical Association announces June 25 to 29, 1923, as the dates for the next Annual Session of the American Medical Association at San Francisco.

HAY FEVER—ITS CURE*

By D. H. TROWBRIDGE, M. D., Fresno, Calif.

My preliminary report of the treatment of hay fever by alcoholic injection was published in 1919 (Cal. State Journal Med., August, 1919).

I feel after treating one hundred and fifty additional patients, justified in the claim that my treatment cures hay fever. My practice is in a climate that is very dry and somewhat dusty—namely the San Joaquin Valley. Consequently there are a great many cases of hay fever. Formerly it was my custom to treat these patients with adrenalin, cocain spray, removal of spurs, and, in years past, by the removal of the turbinate bodies either in toto or in part, as well as by using all other methods of treatment then in customary use. The results were not satisfactory. Realizing the inefficiency of the mode of treatment, I determined to try a suggestion made to me by the late James A. Black of San Francisco—this being that alcohol injected into the nose would cure hay fever. There is no evidence that Black ever used the treatment extensively. If so he did not make further reference to it and I have not found any articles published by him in regard to it.

The first patient treated by this method suffered quite a severe reaction and the symptoms seemed to be much exaggerated for the first few days, after which the reaction subsided and the patient has not had a return of the trouble to this date. Naturally with this encouragement the treatment was carried out on other patients, at first with considerable doubt as to the results. Each patient was treated with the hope that the result might be successful but fearful that it would not be. Now, after several years' use of the alcoholic injection method of treatment, a cure is expected in every patient and failure causes much surprise.

Replies received to a questionnaire sent out in February of this year to one hundred prominent rhinologists in the United States and Canada, show only two men who had ever used the alcoholic treatment for hay fever. One specialist had used it to a considerable extent and a quotation from his letter is given below. The questionnaire was as follows:

How many cases of hay fever have you treated with vaccine?
What kind of vaccine used?
Did you use controls and specific vaccine or stock vaccine?
Kindly give results.
Have you used the alcoholic injection method? How many cases?
What results?

The replies show that a great many rhinologists do not treat hay fever at all, nevertheless they seem to be interested, as many asked for reprints of my paper. About 40 per cent of the answers indicated that they had used the vaccines to a greater or less extent. Some had used stock vaccines from many manufacturers, while others had gone into the matter more scientifically and tested the patient for the specific pollen to which he seemed to react and then treated each patient with a vaccine especially prepared or selected for the individual. The concensus of opinion from the replies received would indicate that those who had used the vaccine in any manner whatever had not been entirely satisfied with the results and that the relief obtained was in not more than fifty per cent of cases. Furthermore the benefit is evidently only temporary lasting perhaps during the season in which the treatment is given, or only while being administered. Certainly my results obtained by the use of alcohol in the treatment of this disease during the past six or seven years have been much better than those obtained by the use of vaccine. While the number of cases is perhaps not so large, many of the cases treated several years ago have had no return of the trouble, although they had been severe sufferers each summer for years previous to the treatment. I now expect about 90 per cent of cures.

Frank R. Spencer of Boulder, Colorado, reported that he had treated several cases with alcohol but did not state his method. He reported some as benefited, others not.

An extract from a letter received from Walter Reedy of Scranton, Pa., gives his experience with the alcoholic treatment. Reedy's plan is entirely different from my own and I quote the following from his letter:

"Injecting the nasal nerve (part of the naso palatine) as they entered the nostrils under the alae nasi. The alcohol was injected on both sides of the fraenum where the mucous membrane is reflected from the upper jaw to the lip. Through infiltration, when successfully done, the nerves are blocked. The patient complains of a numbness of the tip of the nose and upper lip. One patient called it a 'wooden nose.' I have used it in a number of cases of hay fever, rose fever, etc., and where the nerve block has been successful, the results have been good."

My technique has been to inject several minims of 95 per cent alcohol into each lower turbinate beginning at the posterior end and making three or four injections into the body of the turbinate with a long slender needle, also two or three injections of a similar amount of alcohol along the surface of each side of the septum. This is done in each nostril. No attention has been given to any special nerve or group of nerves.

The worst feature encountered in my method of treatment is that it is painful. No local anesthetic has been found that will prevent pain upon the injection of 95 per cent alcohol into the tissue. The patient has no feeling when the needle is inserted, but upon the injection of the alcohol the pain seems to radiate from the nose through the nerves up into the face and superorbital region and for something like a minute or two it is very severe. This is the most disagreeable feature in the treatment and it has kept some patients from receiving the benefit of the treatment who otherwise would have submitted to it. Very nervous patients may, of course, be given a general anesthetic and in the future I expect to use a general anesthetic more frequently rather than try to do the work under local anesthesia.

In most cases there is considerable reaction.

* Read before the Eye, Ear, Nose and Throat Section of the California Medical Association at Yosemite National Park, May 16, 1922.

The mucous membrane is swollen and the patient has a disagreeable sensation of tumefaction for several days, after which it disappears. In many cases, within twenty-four hours the sneezing and disagreeable nasal irritation typical of hay fever disappears permanently. In a few cases the trouble has returned the following season and the patient had to submit to a second treatment. In cases where the results have not been good, the trouble appears to be due to faulty technique by which the alcohol escaped into the throat, or due to improper insertion of the needle, it may have passed through the turbinates and escaped behind into the pharynx. It is not as easy to confine the alcohol entirely to the turbinates as one would suppose and if particular care is not used more or less of it will be lost. When the alcohol is properly injected under local anesthesia, more or less intense pain immediately follows, whereas when it is not properly placed there is no pain. This in one way is a benefit as one can feel assured when the pain immediately follows the injections that the alcohol has been properly placed. Lately I have tried H. M. C. Compound hypodermatically together with local anesthesia which has seemed to lessen the pain somewhat. It is possible that this with local anesthesia will prove sufficient without resorting to a general anesthetic. Submucous resections and other operations may be combined with this treatment.

CASE REPORTS

One case reported in my former paper of August, 1919, was of a young man age 17, who had suffered for years from hay fever, so severe that each summer he was unable to work. He was treated four years ago and within a week was entirely relieved and able to work in the hay field with no return of the trouble. In a recent report he states that he has been entirely cured and is now having no trouble whatever.

Abstracts from the records of a few additional cases are submitted:

Miss H., age about 30 years, complained of hay fever for six or seven years. As a result of the trouble she was compelled to go to the coast each summer. She was given the alcohol injection on June 2, 1919, since which time she has had no return of the disease.

Mr. E., age about 65 years, referred to me by the mother of the young man previously mentioned in the former article. Mr. E. had suffered for twenty-five years from hay fever; had traveled extensively seeking relief and consulted numerous physicians without benefit. One treatment gave him complete relief.

Mr. T., age 19, had suffered for years. Was treated in 1919 and has had no return of the trouble to this date.

Mrs. C., age 19, treated six years ago. She was a severe sufferer from hay fever, practically an invalid during the summer months. A report received from her during the past week advises that she has been practically free from hay fever since the treatment.

Many other cases might be reported.

CONCLUSION

The great benefit of my method is that one treatment is usually all that is required to give permanent relief, whereas with vaccines many injections are required and the treatment must be kept up indefinitely. With the alcoholic treatment I obtain a cure or relief in 90 per cent of cases.

THE EFFECT OF MASSAGE, HEAT AND EXERCISE ON THE LOCAL CIRCULATION*

By ALBION WALTER HEWLETT, San Francisco
(From the Department of Medicine, Stanford University)

Despite the value of physiotherapeutic methods in the treatment of diseases which involve the extremities, we are still relatively ignorant of the manner in which these produce their beneficial effects. This is so largely because the study of joint and muscle functions has hardly advanced beyond the simplest measurements of motion and strength. Broadly speaking, physiotherapy is still in an empiric stage. Its methods have been and are being developed by the method of countless trials in one direction or another. The rational explanation of the results obtained is still fragmentary and scientific studies have not advanced sufficiently far in this field to give to physiotherapy the assistance already given to drug therapy and to treatment by the methods of immunology. None the less, a consideration even of certain functional changes, produced by physical methods of treatment, helps to clarify one's conception of what is happening in the tissues during the treatments.

My interest in this subject was awakened by studies on the blood flow in the arm which were carried out several years ago in association with J. G. Van Zwalenburg and others. These studies demonstrated plainly that the blood flow in the arm was readily and markedly influenced by certain physiotherapeutic procedures and that it was relatively unaffected by powerful drugs given in full therapeutic doses. Though our experiments have been published for some time it may yet be of interest to review the results, together with results of others, on account of the light they throw on certain methods commonly used in physiotherapy.

The arm is composed of skin, muscle and bone, together with various connecting tissues. Changes of circulation which occur in the arm may be assumed to occur under similar conditions at other portions of the surface of the body, where skin, muscle and bone make up the major part of the tissue.

It is well known that heat tends to increase the amount of blood in the heated tissues. The arm is said to swell as much as 70 c.c. when heated. Cold, if not too intense and too prolonged, has an opposite effect. Rings, gloves and shoes fit more loosely when one is chilly and more tightly when one is warm. These changes in volume are accompanied by corresponding changes in the rate of blood flow. The continued application of hot water to the arm increases the local rate of blood flow from four to eight times, and the continued application of cold causes the local rate to fall to one-half or one-fourth of the original. In one of our experiments, for example, the range of blood flow in the arm as a result of thermic influences varied from 2 to 40 c.c. per 100 c.c. of arm substance per minute.

The increased rate of blood flow produced by

* Read before the Section on Technical Specialties (California Association of Physiotherapists) at the Fifty-first Annual Meeting of the California State Medical Society.

heat is not a purely local phenomenon. Shortly after one arm is plunged into hot water the blood flow is increased not only in this arm but also in the opposite one, the latter being less markedly affected. In general the application of heat to any portion of the periphery of the body causes not only a local increase of blood flow but it appears to cause an increased circulation in all portions of the body surface. The response of distant portions of the surface is often so prompt that it must be due in part to nervous reflexes.

Thermic influences may bring about a redistribution of blood in still a third way. This is through an alteration in the body temperature. We know that if a person becomes overheated, the heat-regulatory centers throw into operation all those mechanisms which serve to lower the body temperature. Most important of these is an increased rate of blood flow through the surface covering of the body. This warms the skin and so increases the heat losses from the body. The central mechanism which regulates the body temperature is sensitive to slight alterations in the temperature of the blood which comes to it. If any procedure raises the temperature of the body, even slightly, then the regulatory mechanism tends to send more blood to the periphery of the body in order to reduce the temperature. Thus we see that thermic influences alter the rate of circulation at the surface of the body in three distinct ways: (1) through their local effects, (2) through reflex influences, and (3) through altering slightly the temperature of the blood which goes to the brain.

This latter appears to me to be of paramount importance in securing a good reaction after the cold procedures. Every hydrotherapeutist knows that the patient must not be allowed to become chilly after a cold procedure and the whole technic of general hydrotherapy is designed so as to obtain that feeling of warmth and comfort which characterizes a good reaction. This is accomplished largely by measures which prevent heat losses from the body. The rooms are kept warm, the patient is given a preliminary hot treatment, and the cold procedure is made very brief. The heat added to the body during the preliminary treatment more than compensates for what is extracted during the cold procedure. The temperature of the body is a little elevated; and although the cold procedure by its local effect drives the blood from the surface, the latter soon returns after the cold is removed and the skin remains warm because of the slight increase in body temperature. Vigorous persons commonly forego the refinements of the hydrotherapeutic institute and obtain reactions in cold rooms and without preliminary hot procedures. It appears to me that they are able to do this largely because vigorous exercise during the bath liberates heat within the body. This liberation, combined with a constriction of surface blood vessels during the cold procedure, more than overcomes the tendency of the cold to extract heat from the body. At the end of such a cold bath the body temperature is actually higher than at the beginning and the individual is left with a pleasing feeling of warmth that persists after the bath is over. In the course of the experiments referred to above, I took not a few cold showers after my body temperature had been slightly reduced by prolonged exposure; and I can testify that under such circumstances even one who ordinarily reacts well and who is comfortable during and immediately after the shower is apt shortly to experience intense chilliness that persists until the body temperature has finally been raised to the proper level. Thus it seems to me that one of the essential conditions for an enduring reaction after a cold procedure is a maintenance or even a slight elevation of the body temperature as a net result of the entire procedure. This ensures the continued feeling of warmth and the normal or increased blood flow to the surface that characterizes a good reaction.

The blood flow through the arm is accelerated not only by heat but also by the voluntary use of the local muscles. We found, for example, that the rate of blood flow in the arm may be increased to from three to eight times the resting flow by rapidly opening and closing the fist. Of no little interest are those observations made by others which indicate that this increase of blood flow during exercise depends less upon the mechanical effect of the motion than upon vasomotor effects caused by voluntary innervation of the muscles used. Muscular contractions produced in animals by stimulating the local nerves seem to have been much less effective in accelerating the local blood flow than the muscular contractions produced by voluntary innervation. Furthermore Weber reported that marked swelling of the arm may be produced in motionless persons during hypnotic sleep merely by the suggestion of motion in this arm. Thus it would appear that the marked increase in local blood flow which accompanies muscular movements is due largely to the voluntary effort made to use the muscles. Here we have suggestive physiologic grounds for encouraging a patient repeatedly to make the effort to use an extremity provided use is desired; even though on account of injury or disease he can actually move it very little.

So far as the local blood flow is concerned, massage is not the equivalent of exercise. Exercise causes a marked swelling of the arm due to the increased amount of blood that it contains, but massage produces no appreciable effect upon the arm volume. Under suitable conditions therefore massage should be combined with voluntary efforts on the part of the patient to use his muscles.

We have seen that two types of procedure commonly used in physiotherapy have an extraordinary effect in accelerating the blood flow through an extremity. These are the voluntary use of the muscles and the application of heat either local or general; and I may repeat that no medicine produces an effect even remotely comparable to that caused by these physical methods. It seems to me evident that such a marked acceleration of the circulation as is produced by these means cannot be without influence upon local disease.

EDITORIALS

MEDICAL DEFENSE AND INDEMNITY DEFENSE

The Council on May 18th last, directed the secretary of the State Society to send postal questionnaires to members on the subject of Indemnity Defense. Three questions were asked, as follows:

1. Are you a member of the Indemnity Defense Fund?
2. Are you otherwise insured against malpractice?
3. If so, name of company or companies, with the amount in each company.

Three thousand four hundred and twenty-five cards were sent out and some of the replies received have occasioned this article.

The questionnaire was prompted by the desire of the Council to obtain data which would be of value in meeting adequately a question which merits earnest consideration by each of the society's members; namely, strengthening our organization to resist unmeritorious claims and suits.

These suits are increasing in number; a greater number of cases are being decided in favor of claimants, and the size of judgments rendered in these cases is becoming larger.

Some members of the society, despite the strongest evidence to the contrary, still seem to feel immune to this type of attack on their reputation and property. This fancied security frequently is lost under startling and disturbing circumstances. Our records show that these suits are brought against physicians in all kinds of practice, whether surgeons or not, and without any basis in scientific facts.

Some of the answers received to the questionnaire suggest the following statement: Any member of the society in good standing is entitled in any malpractice case, where his position is meritorious, to payment of all court costs and attorney's fees in his behalf. This protection, available to every member in good standing, is termed Medical Defense. If in such a case, a judgment for damages is obtained against a member, the member must pay such judgment himself; in other words, the society merely furnishes the attorney and pays court costs.

In order to provide for protection against possible adverse judgments, the society established the Indemnity Defense Fund in 1916. Any member in good standing can join this Fund on payment of $15 in cash, and give his note for $15 without interest, payable one year thereafter. In all malpractice claims or cases against a member of the Fund, the society pays all court costs, furnishes the attorneys, and in event of adverse judgment, pays such judgment up to the amount of $5,000 in any one case.

As to malpractice claims and cases, therefore, the society affords two types of service to members; the first, Medical Defense, which includes court costs and attorney's fees, but does not take care of adverse judgments; the second, Indemnity Defense, which includes the payment of all court costs and attorney's fees and any adverse judgment up to the sum of $5,000.

Some of the members ask: "Do you advise me to carry insurance in addition to my membership in the Indemnity Defense Fund?" The council and officials of the State Society have taken a uniform stand on this question, which has been presented to members by letter and articles in the Journal heretofore. If a member has no insurance, he is advised to join the Fund; if he has insurance, he is advised to join the Fund. A member carrying insurance is advised not to drop it, but keep it in force for the reasons above stated. Verdicts in this type of case, when rendered, show a decided tendency to increase in size, typically in certain types of action. Of course, a great deal depends on the doctor's clientele, the character of work done by him, the number and reliability of assistants and numerous other phases, as to which we will be glad to advise any member who will write to this office in detail concerning it.

PROPAGANDA

The subtleties and finer points, as well as the curiously oblique ethics which form the basis of "propaganda" as distinguished from "advertising" on the one hand and "education" on the other hand, are perhaps the most confusing, least understood and yet one of the most important subjects before the public. Propaganda by the ton is being fed to the public daily everywhere, disguised as "news," "education" or "informative publicity."

Physicians should study the subject seriously in their own interests and more particularly in the interests of their friends and patients. This because the broad field of public health and medicine is proving one of the most profitable for "propagandists" who are succeeding to a degree in many instances and by various means in "educating" not only the public, but some physicians in health movements, methods and procedures.

Our mail contains many inquiries from physicians as to the merit of this or that welfare organization, new (?) suggestions, methods or what not. In most of these instances a little investigation and serious thought would have uncovered the truth.

Recently the North American Review published a series of three articles upon this subject and E. K. Strong has a splendid article in the last issue of the Scientific Monthly. Strong says:

"The word 'propaganda' means essentially the spread of a particular doctrine or a system of principles, especially when there is an organization or general plan back of the movement. Propaganda differs from 'education,' with which it is purposely confused, in that in the case of the former the aim is to spread one doctrine, whereas in the case of the latter the aim is to extend a knowledge of the facts as far as known.

"Advertising men have never been able to agree on a definition of 'advertising' and I should not want to attempt here what they have failed to do. But I think we can distinguish between advertising and propaganda by saying that advertising is usually concerned with making known and desirable a definite commodity or service with the definite

aim of leading many individuals, as such, to acquire the commodity or service. Propaganda includes many types of advertising, but it is mainly concerned with the subtle presentation to the public of information so chosen and so focused that among many individuals there develops a general 'point of view' which is favorable to the aim of the propagandist and leads to action in that general direction. A further distinction between these two methods of influencing people pertains to the **methods** employed rather than the **object**. The advertiser buys space upon which appears his message, and the reader knows it as a paid advertisement. The propagandist may advertise, but he especially aims to employ space he did not buy, at least directly, and not to permit the reader to know that the material is propaganda. He believes his material will have greater effect when its source is unknown. . . .

"We are so accustomed to our political machinery that we do not often stop and ask ourselves whether it is geared up so as to serve society in the best way. Only when some enthusiastic social uplifter boasts that she and four others alone put a measure through a state legislature by the use of skillful lobbying, or a secretary of a business man's organization calmly announces months in advance that Congress will do away with a bureau because his organization is demanding such action, and his prophecy comes true, does one wonder whether some sort of control of propaganda would not be worth while even here. And one waxes quite indignant, as did a former Secretary of War, when he comes to realize that much of the propaganda for bringing back the bodies of our dead soldiers was instigated by the journal of the undertakers and casket makers."

He concludes:

"As far as I can see, society has reached the point in its development when it must take motives into account, because man has now learned how to arouse motives to action in an economical and wholesale way. And in regulating motives society must come to evaluate the sentiments that propaganda is aimed to create, and to regulate in some way the use of phrases arousing emotions as distinguished from phrases appealing to rational consideration. Without control in some way of the emotional element in propaganda, legal action will never stop the most dangerous of propaganda which arouses a sentiment first of all and then at the proper moment in one fell swoop precipitates that sentiment into action."

It would be well for physicians as guardians of public and personal health to establish the habit of critical reflection and make a point of fair interpretation for their patients of much that now appears in print as "education," "public health and medicine information." The subjects discussed include practically the entire field of medicine and public health and there is usually a motive and an interested organization just beneath the surface.

VITAMINS

Vitamins should be purchased from the market, the grocery and the dairy instead of the drug store.

Some pharmaceutical houses are spending a great deal of money in efforts to induce physicians to prescribe vitamins. Patent medicine vendors and a host of other quack concerns are spending huge amounts of money in an attempt to "educate" (?) the public as to the great value of vitamins, and, of course, the product offered by each advertiser is the only one that contains the real Simon-pure, life-giving "A" "B" and "C" vitamins.

It is the duty of physicians to inform their patients and it is the duty of the medical profession to inform the general public that the best and most useful and all that is necessary of vitamins can be purchased for a few cents a day from the dairy and the market. Furthermore, it is our duty to tell the public that some of the most extensively advertised and used of these products have not sufficient vitamin "C" to protect guinea pigs from scurvy when given in doses recommended as sure protection for children.

In fact, except under certain special conditions, which can be appreciated only by the educated physician, there is no excuse, except one of financial profit for soul-scarred commercialists, for creating a demand for these products.

HOSPITAL BETTERMENT WEEK IN CALIFORNIA—SECOND ANNUAL CONVENTION OF THE HOSPITALS OF CALIFORNIA.

(Held Under the Auspices of the League for the Conservation of Public Health, Maryland Hotel, Pasadena, September 5, 6, 7, 8, 1922.)

A real post-graduate week of study and instruction in hospital betterment; a program of constructive discussion, question and answer conference, and application for all people interested in any phase of hospital betterment.

During the same week, there will be meetings of the Council of the Medical Society of the State of California; of the Council and officers of the State Society with the officers of County Medical Societies from all parts of the State; and of the Program Committee of the State Medical Society, including the section officers of all sections of the State Medical Society. There will be exhibits, scientific, technical and commercial, showing the best in professional and technical service in California hospitals, as well as the best in equipment, furnishing and supplies.

A strong committee from Southern California, under the chairmanship of Dr. Charles D. Lockwood, is arranging an interesting and attractive social and recreational program. Headquarters will be at the Maryland Hotel, Pasadena. This hotel, as well as others in Pasadena and Los Angeles, have made exceedingly satisfactory American plan rates. The social and get-together features of this convention, as well as the serious sessions, will be very attractive.

Every hospital in California, regardless of its ownership, method of management, whether it is general, special or private, is invited and urged to send as many people as possible to the convention. Each hospital, regardless of its size and character, is entitled to delegates as follows: One representing each of the following: Ownership, directorate, administration, staff, nursing and all other professional and technical departments.

For hotel reservations, address Mr. H. M. Nickerson, resident manager, Maryland Hotel, Pasadena.

For any problem of any kind pertaining to the convention, address Dr. Charles D. Lockwood, chairman Committee of Arrangements, 295 Markham Place, Pasadena, or Dr. W. E. Musgrave, chairman of the Section on Medical Economics, Education and Hospitals, 806 Balboa Building, San Francisco.

SYNOPSIS OF PROGRAM

All meetings will be held in the Maryland Hotel, Pasadena.

First Meeting—Tuesday, September 5, 10 to 12:30.
This meeting will be devoted to special informative 10-minute lectures of vital interest to everybody.

Second Meeting—Tuesday, September 5, 2:30 to 5 p. m.
This meeting will be given over to general consideration of common hospital problems; four speakers,

ten minutes each, each subject to be followed by a general discussion. Meeting to be closed by 30 minutes of questions and answers. Anybody in the audience may ask any questions on any phase of hospital administration.

(This question and answer conference will close every meeting of the convention.)

Third Meeting—Wednesday, September 6, 10 to 12:30. The general subject of this meeting is "The Physical Plant of the Hospital." There will be three 10-minute addresses with free discussions by everybody, and the meeting will close with thirty minutes of questions and answers.

Fourth Meeting—Wednesday, September 6, 2:30 to 5 p. m. The general subject for this meeting will be, "Owners, Governing Bodies and Chief Executives of Hospitals." Again there will be three 10-minute addresses, followed by general discussion, and the meeting to be closed by a question and answer conference as mentioned above.

Fifth Meeting—Thursday, September 7, 10 to 12:30. The general subject will be, "Clinical Departments and Services for both the Hospital and Dispensary. The carefully prepared ten-minute addresses at this meeting will include questions of staff organization in general, as well as by departments; the relation of the general practitioner to the hospital staff; the relation of groups to hospitals and the relation of dentistry to the hospital, together with the usual standard staff departments. The general four-minute discussions will be open to everybody, and the meeting will be closed by the thirty-minute question and answer conference.

Sixth Meeting—Thursday, September 7, 2:30 to 5 p. m. This meeting will be devoted to the General Utility Departments and Services of the hospital. The ten-minute addresses will include pathology and clinical laboratories; the hospital department of public health; the departments of radiology, and the technical departments of physiotherapy, pharmacy, nursing, public health nursing and medical social service, clinical records and library. The four-minute discussions will be general and every one will be invited to take part in them. The meeting will close with the thirty-minute question and answer conference.

Seventh Meeting—Friday, September 8, 10 to 12:30. This meeting will be devoted entirely to the problems of Hospital Administration. The selected ten-minute addresses will cover the field of general administration; finances and accounting; property and supplies and transportation; laundry and linen services; subsistence and dietetics. Four-minute discussions will be open to everyone, and the meeting will close with thirty-minute question and answer conference.

Eighth Meeting—Friday, September 8, 2:30 to 5 p. m. The concluding meeting will be a business meeting, with discussion of reports of the resolutions committee and other committees.

Hospital Betterment Service Bureau

In addition to the regular program, members of the Section on Medical Economics, Education and Hospitals of the League, assisted by experienced persons on every character of hospital problem, will hold special informal conferences every evening at 8 o'clock in the League headquarters at the Maryland Hotel. These meetings are open to all persons, and anyone with any particular hospital problem is invited to present it for discussion and solution at these conferences. Only specific problems will be considered at these 8 p. m. meetings.

OFFICERS AND COMMITTEES, LEAGUE FOR THE CONSERVATION OF PUBLIC HEALTH

Section on Medical Economics, Education and Hospitals

W. E. Musgrave, M. D., chairman; William Ophuls, M. D., John H. Graves, M. D., Percy T. Magan, M. D., Dudley Fulton, M. D.

Officers

Dudley Smith, M. D., president; Granville MacGowan, M. D., vice-president; W. T. McArthur, M. D., secretary; W. B. Coffey, M. D., treasurer; Hartley F. Peart, counsel.

Executive Committee

C. D. McGettigan, M. D., chairman; Walter V. Brem, M. D., O. D. Hamlin, M. D., Saxton T. Pope, M. D., James W. Ward, M. D., Celestine J. Sullivan, executive secretary.

Committee on Arrangements for the Convention

Dr. Charles D. Lockwood, chairman; Bishop Joseph H. Johnson, Good Samaritan Hospital; Mrs. Laura L. Mitchell, Pacific Hospital; Mr. Norman Martin, Los Angeles County Hospital; Dr. N. N. Wood, Los Angeles County Hospital; Miss Melisse Wittler, Methodist Hospital; Mrs. Harriet W. Pahl, Angelus Hospital; Dr. E. T. Dillon, St. Vincent's Hospital; Sister Mary Ann, St. Vincent's Hospital; Dr. Percy T. Magan, White Memorial Hospital; Dr. Joseph K. Swindt, Pomona Valley Hospital; Dr. C. Van Zwalenburg, Riverside Community Hospital.

Rules of the Hospital Convention

1. All meetings are open to the public. Physicians, dentists, physiotherapists, nurses, public health nurses, medical social workers, dietitians, radiographers, laboratory technicians, architects and other persons interested in the Hospital Betterment Movement are especially urged to attend these meetings.

2. The speaker opening a subject will be limited to ten minutes; the discussions will be limited to four minutes each. No discussant may speak more than once upon any topic, and the chair may not grant extension of time beyond the specified limit. General discussion by delegates and visitors invited.

3. Each hospital is entitled to send one official representing ownership; its directorate; the administration; the staff; nursing and all other professional and technical departments.

4. All resolutions shall be presented in writing to the chairman and referred to the Committee on Resolutions, without comment.

Other Meetings Held in Connection With the Hospital Convention

The council of the State Medical Society will hold two meetings (for Councilors only). The first meeting will be held Friday, September 8, at 10 a. m., at the Maryland Hotel. It will adjourn for luncheon at the hotel and continue its session until the business is transacted. The second meeting will be held Friday evening, September 8, at 8 o'clock, at the Maryland hotel. This meeting is for a special purpose and will be an executive session.

There will be a meeting of the Council with State and County society officers, Saturday, September 9, at 12:30, at luncheon in a special dining room at the Maryland hotel. At this meeting it is requested that presidents, secretaries and assistant secretaries and any other officers of county societies from all over the State, meet with the Council and officers of the State Society for discussions of problems affecting the progress of medicine and the welfare of medical organization.

The program committee of the State Medical Society will meet with section officers of each section of the State Society, Saturday, September 9, 10 a. m., Maryland hotel. This is an important meeting, to arrange the program and plans for the next annual meeting of the State Society, as well as for the conduct of the State Society's business, and co-ordinating it with the various section activities of the State Society throughout the year.

Tuberculosis Association and Illinois "State Medicine"—"The Illinois Tuberculosis Association is distributing a pamphlet dealing with the tuberculosis clinic as it is conducted by the association. In view of the fact that many physicians in the State are more or less antagonistic to what is termed 'State medicine,' the Illinois Tuberculosis Association explains in detail the purpose of its clinics.

"'The clinics are diagnostic clinics. They have nothing to do with the treatment of patients. They are held only in conjunction with the county medical society or the local medical profession. The individual local physicians are invited to bring their own patients to the clinics or to express their approval of their patients being invited to the clinics. The clinics are held chiefly with the medical profession, for the medical profession and by the medical profession.

"'Nurses and other arranging clinics are particularly urged not to present patients for examination except with the approval or in the presence of the patient's family physician. When the family physician is unable, for any reason, to attend the clinic where his patient is examined, the nurse is expected to convey to the family physician the diagnosis and suggestions made by the clinician.'"—(Long Island Medical Journal, May, 1922.)

STATE SOCIETY

ABSTRACTS FROM THE MINUTES OF THE 130th, 131st, 132nd AND 133rd MEETINGS OF THE COUNCIL OF THE STATE MEDICAL SOCIETY

(Held at Yosemite National Park, May 15 to 18, 1922)

Madera County Medical Society—The secretary reported that the physicians of Madera County had voted to organize a county society and had requested a charter from the State Society. Upon motion of Bine, seconded by Van Zwalenburg, it was

Resolved, That this newly created medical society be recognized and the secretary authorized to issue a charter to them.

Industrial Accident Law—The question of a circular letter recently sent out by the Industrial Accident Commission requiring every physician to report to the Commission all accident cases treated by him, whether industrial cases or not, was brought up for discussion. On motion of Bine, seconded by Graves, it was

Resolved, That the matter be referred to the general attorney for advice as to whether or not the law requires that every physician report to the Industrial Accident Commission every accident he is called upon to serve;

Resolved further, That if in the opinion of our attorney this is the correct interpretation of the law, he advise the Council of the method of procedure to endeavor to have this law amended.

Appointment of Trustee of Indemnity Defense Fund—The term of office of Rea Smith as trustee of the Indemnity Defense Fund having expired, upon motion of Kress, seconded by McArthur, it was

Resolved, That William Duffield of Los Angeles be appointed to fill the vacancy caused by the expiration of the term of Rea Smith.

Advertisements of Physicians in Newspapers—A letter was presented by the secretary from Dr. ——— in regard to the rather flamboyant advertisements in certain newspapers by certain physicians in Fresno, San Francisco and elsewhere, and asking for our instructions. The secretary stated he had answered the letter to the effect that the matter would be referred to the Council, but that undoubtedly the advertisements in question were unethical. It was voted by the Council that the communication of the secretary be approved and that the advertisements in question be brought to the attention of appropriate local county societies.

Baynes' Article in Woman's Home Companion on the Truth About Vivisection—It was voted that a letter be written to the Woman's Home Companion, commending them on their stand in regard to vivisection.

It was further voted that a copy of the letter be published in the State Journal of Medicine, with an editorial note suggesting to all members that they also write and express their approval of the stand taken by the Woman's Home Companion and the discussion they are giving the question in their publication.

Roster of State Society Members—Discussion was had as to the advisability of printing a roster of members of the State Society for 1922. Upon motion duly made and seconded, it was voted that the Society discontinue the printing of the roster.

New Sections on Scientific Work—The Council having heard the report of the secretary on proposed new sections, upon motion of Bine, seconded by Paterson, it was

Resolved, That the creation of the following new sections be approved, and the secretary be instructed to take the necessary steps to make this action effective:

1. Section on Physiology, Chemistry and Pharmacology, including Physiological Chemistry, Biological Chemistry, Pharmacy, Chemotherapy, and similar allied sciences;
2. Section on Anatomy, including Surgical Anatomy, Embryology and similar closely allied sciences;
3. Section on Applied Biology, including Parasitology, Serology, Immunology and similar closely allied subjects;
4. Section on Dermatology.

Reorganization of the Council—Upon motion of Edwards, seconded by McArthur, C. G. Kenyon was unanimously re-elected chairman of the Council for the ensuing year.

Appointment of Councilor for Third District—Upon motion of Paterson, seconded by Brainerd, Garth Parker of Salinas was appointed to fill the vacancy in the Third District caused by the resignation of T. C. Edwards as councilor for that district.

Indemnity Defense Fund—After general discussion of methods of increasing membership in the Indemnity Defense Fund and of the cost of medical defense, upon motion of Paterson, seconded by McArthur, it was

Resolved, That the secretary be instructed to circularize the members of the society, to ascertain how many are insured in private insurance carriers and the amount of insurance carried.

MINUTES AND PROCEEDINGS OF SECTIONS OF THE FIFTY-FIRST ANNUAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

(Only part of the Sections have submitted minutes. These are published.)

SECTION ON GENERAL SURGERY

CHARLES D. LOCKWOOD, Chairman
EDMUND BUTLER, Secretary

First Meeting, May 16, 1922, at 8 p. m.—The fourth annual session of the General Surgical Section was called to order by Chairman Lockwood. Following the chairman's address, the minutes of the 1921 session were read and approved. Papers read during the first meeting were as follows: "Amputation Region of the Knee Joint," by Howard H. Dignan of San Francisco; discussed by Emmet Rixford of San Francisco, Leo Eloesser of San Francisco and W. W. Richardson of Los Angeles. "The Hemorrhoid Problem," by Sol Hyman of San Francisco; discussed by H. H. Shirk of Pasadena, G. Rothganger of Oakland, E. Rixford of San Francisco, W. A. Clark of Oakland, LeRoy Brooks of San Francisco, O. O. Witherbee of Los Angeles, W. A. Jones of Riverside. "Migratory Tumors of the Abdomen," by Asa W. Collins of San Francisco; discussed by Burt S. Stevens of San Francisco; "Amoebic Abscess of the Liver," by Horance J. Brown of Goldfield, Nevada; discussed by Herbert Gunn and Herbert Moffitt. The paper of Rea Smith of Los Angeles was not read because of the inability of Dr. Smith to attend. "The Underlying Principles of Plastic Surgery," by J. A. Pettit of Portland, Oregon, was transferred from the May 18 session; discussed by William J. Mellinger of Santa Barbara. "Tumors of the Breast Arising During Lactation and Pregnancy," by Alson R. Kilgore of San Francisco; no discussion.

Second Meeting, May 17, 1922, at 2 p. m.—The meeting consisted in a symposium on bowel obstruction with the following papers: "Indications For and Results of Anchoring the Head of the Colon," by O. O. Witherbee of Los Angeles. Andrew S. Lobingier was not able to attend the meeting. The secretary was notified February 25, 1922, but through some mistake the program was not corrected. "Bowel Obstruction, Diagnosis and Treatment," by Emmet Rixford of San Francisco. "Some Observations on Intestinal Obstruction," by Harold Brunn and George K. Rhodes; read by Harold Brunn. "Bowel Obstruction Following Abdominal Operations Occurring During Convalescing Period," by Alanson Weeks and LeRoy Brooks; read by LeRoy Brooks; discussed by E. C. Rich of Ogden, Utah; W. W. Cross of Fresno, James F. Percy of San Diego, W. L. Huggins of Los Angeles, and J. H. Shepard of San Jose. "Surgical Study of Periarterial Sympathetic Fibers," by C. Latimer Callender; discussed by Stanley Stillman, Leo Eloesser, E. Rixford, H. Brunn, P. K. Brown, E. I. Bartlett, all of San Francisco, and W. A. Clark of Oakland. Adjournment.

Third Meeting, May 18, 1922, at 2 p. m.—Election of officers for the 1923 session. The chairman appointed O. O. Witherbee, W. W. Richardson to act with W. A. Clark, the retiring chairman of 1921, on the Executive Committee. Stanley Stillman of San Francisco was elected chairman. Harlan Shoemaker of Los Angeles, secretary and Leo Eloesser, assistant secretary for 1923.

The following papers were read: "Adenomata of the Thyroid," by John Hunt Shepard of San Jose; discussed by Carl Hoag and E. I. Bartlett. Clarence Toland did not appear to read his paper. "Compression of the Lung in Tuberculosis, Medical and Surgical Aspects," by Leo Eloesser of San Francisco and Philip King Brown of San Francisco. "The Diagnosis and Treatment of Surgical Lesions of the Chest," by Charles D. Lockwood of Pasadena; discussion of the two previous papers by W. J. Kerr of San Francisco, C. A. Warmer of Los Angeles, C. L. Callender of San Francisco, D. Frick of Los Angeles, H. E. Schiffbauer of Los Angeles and O. O. Witherbee of Los Angeles. "False Diverticulitis of the Sigmoid," by Stanley Stillman of San Francisco; discussed by E. Rixford, J. H. Shepard and C. Hoag.

The attendance was very good at all three sessions. W. A. Clark of Oakland moved that a vote of thanks be extended to the chairman, Charles D. Lockwood, for providing a very interesting and timely program.

SECTION ON UROLOGY

G. W. HARTMAN, Chairman
LOUIS CLIVE JACOBS, Secretary

The Urological Section of the Medical Society of the State of California held meetings on May 15 and 16. The program, as published in the May issue of the Journal was carried out, except that the paper of Granville MacGowan of Los Angeles was not read, due to his absence. The Nominating Committee presented the names of Robert V. Day for chairman and Louis Clive Jacobs for secretary for the ensuing year. It was duly moved and seconded that the nominations be closed and the motion was carried. The candidates were then duly elected.

SECTION ON OBSTETRICS AND GYNECOLOGY

HARRY M. VOORHEES, Chairman
L. A. EMGE, Secretary

The following is an abstract of the minutes of the meetings of the Section on Obstetrics and Gynecology. The following resolutions were passed:

1. That one hundred dollars be expended from the "Stenographer's Fund" to cover the expenses of recording and transcribing the discussions of the various papers given.
2. That the secretary of the State Society be notified that all discussions, properly edited, shall be published together with the original article in the Journal of the State Society.
3. That the secretary of the Section on Obstetrics and Gynecology shall keep a registration list of all physicians who wish to take active part in the section meetings.
4. That next year's program shall include at least two meetings in which symposiums will take the place of individual papers.

The symposiums to be on: (1) Sterility, (2) Posterior Positions and Their Treatment, (3) Operative Versus Radiation Treatment of Benign and Malignant Tumors, (4) The Application of Episiotomy and Low Forceps. All those who wish to take part in the symposiums should communicate with the secretary of this Section at once so that special problems may be assigned. The officers elected for the coming year are: Dr. L. A. Emge, chairman, Stanford University Hospital, San Francisco, and Dr. J. Morris Slemmons, secretary, Los Angeles.

SECTION ON NEUROPSYCHIATRY

W. F. SCHALLER, Chairman
W. B. KERN, Secretary

The session was well attended, evidently larger than any previous session. The program was carried out in full. Officers elected for the ensuing year were: Ross J. Moore of Los Angeles, chairman, and Charles I. Tranter of San Francisco, secretary.

SECTION ON ORTHOPEDIC SURGERY

W. W. RICHARDSON, Chairman
G. J. McCHESNEY, Secretary

The first meeting of the Section was held on Tuesday afternoon, May 16, W. W. Richardson, Los Angeles, presiding. After his opening address, a paper by A. L. Fisher, San Francisco, on "Congenital Elevation of the Shoulders With Operation For Cure," was read by Sol Hyman, San Francisco, in the absence of Fisher. The next paper was "The Treatment of Painful Affections Involving the Cervical Vertebrae," by H. L. Langnecker, San Francisco. The third paper was by C. G. Stivers, Los Angeles, the subject being "Re-Education of Crippled Children." The last paper of the afternoon, illustrated by numerous lantern slides, was on "Repair of Tendons in the Fingers," by Sterling Bunnell, San Francisco. H. A. Ryfkogel, San Francisco, did not appear to read his paper as per program.

The second meeting was held on Wednesday evening, May 17. The first business was the election of Section officers, which resulted in the appointment of George J. McChesney, San Francisco, as chairman for the ensuing year, and H. H. Markel, San Francisco, as secretary. As the meeting is to be held in San Francisco, it was thought advisable to have both officers from that city. There being no other Section business the scientific program was continued. James T. Watkins, San Francisco, read a paper on "Dislocation of the Hip Into the Obturatur Foramen." George J. McChesney, San Francisco, read a paper on "The Modern Treatment of the Weak or Flat Foot." A Gottlieb, Los Angeles, read a paper on "Brisement Forces and the Pre- and After Treatment." H. L. Schurmeir, Los Angeles, read a paper on "Congenital Deformities." This closed the meeting, which was regarded as highly satisfactory by all who attended.

SECTION ON INDUSTRIAL MEDICINE AND SURGERY

E. W. CLEARY, Chairman
PACKARD THURBER, Secretary

First Meeting, May 15, 1922—The secretary suggested to the various members that they hand in abstracts of their papers to the Section's secretary early in the year to facilitate preparation of the program. The address of the chairman covered some of the important problems in industrial surgery. The chairman announced that due to illness three of the men scheduled to give papers were unable to attend. The following papers and discussions ensued: "The Necessity for More Accurate Data in the Surgeon's Permanent Disability Report," F. E. Raynes. "Misuse of the Industrial Accident Fee Schedule." Morton Gibbons; discussion by Gayle G. Mosely, Hunkin and Carl Hoag of San Francisco, H. J. Brown of Goldfield, Nevada; E. C. Cleary and Morton Gibbons, San Francisco. A motion was made by Charles Mooney of Santa Rosa that a committee be appointed to draw a resolution to the State Society regarding fees and underbidding. The chairman appointed on this committee Morton Gibbons, San Francisco, chairman; Charles Mooney, Santa Rosa and Philip Stephens, Los Angeles. The next paper was "Resection Distal End of the Ulna For Shortening of the Radius Following Fracture," Carl Hoag, San Francisco; discussion by Spier of Los Angeles, George McChesney, T. J. Watkins, E. W. Cleary and Carl Hoag of San Francisco. So-called "Chauffeur's Fractures" was the subject of a paper by Philip Stephens, Los Angeles; discussion by Langnecker, Hunkin and Stephens, San Francisco.

Second Meeting, May 18, 1922—"The Necessity For An Immediate and Thorough Roentgenological Study of All Injuries to the Spine," H. W. Chappel, Los Angeles; discussion by Schumier, Santa Barbara, Harlan Shoemaker, Los Angeles, Hunkin, Adams and Gould, San Francisco, Chappel of Santa Barbara. Philip Stephens of Los Angeles was elected chairman, and Packard Thurber, Los Angeles, secretary. The committee appointed at the first meeting to draft a resolution on fee cutting made a report. The resolution was passed. (This resolution was published in the minutes of the Council in the July Journal.) "Fracture Pelves With Particular Reference to Dislocation of the Sacro Iliac Synchondroses," Harlan Shoemaker, Los Angeles; discussion by Prince, Hunkin, Cleary, Moseley, McChesney and Shoemaker of San Francisco. "Industrial Medicine and the General Practitioner," Gayle G. Mosley; discussion by Morton, Gibbons, Cleary and Mosley, San Francisco. "Physiotherapy Treatment in Industrial Rehabilitation," A. R. Gould; discussion by Morton Gibbons, Koye, Mellinger, Shoemaker, Adams, Hunkin, McChesney, Gibbons, Cleary and Gould. Harlan Shoemaker of Los Angeles made a motion that a committee be appointed to investigate physiotherapy and report at the next industrial section meeting. The motion was carried and the chairman announced that a committee would be appointed at a later date.

SECTION ON PATHOLOGY AND BACTERIOLOGY

WM. OPHULS, Chairman
R. W. HAMMACK, Secretary

First Meeting, May 16, 1922, at 2 p. m.—Presided over by William Ophuls, chairman. First paper by F. R. Nuzum, Santa Barbara, on "The Effect of X-ray Upon the Structure and Bacterial Flora of the Tonsils"; discussed by Von Adelung, Evans and Ophuls. Second paper by R. B. Hill, Los Angeles, "A Clinical and Pathological Study of Fifty Cases of Hyperthyroidism"; discussed by Rusk, Evans, Ophuls and Hill. Third paper by W. T. Cummins, San Francisco, "Germanium Dioxide and Erythropoiesis"; discussed by Wm. Ophuls. Fourth paper by McArthur of Napa, Cal., "Encephalitis Lethargic"; discussed by Hammack, Cummins and McArthur. Ivan C. Hall of Berkeley was unable to present his paper on "Some Limitations on the Agglutination Reaction in the Indentification of Sporulating Anaerobs." The chairman appointed a committee, consisting of Evans, Rusk and Hammack, to nominate candidates for Section officers. Meeting adjourned at 4:30 p. m.

Second Meeting, May 17, 1922, 2 p. m.—Wm. Ophuls, chairman, presiding. Committee on nominations reported, nominating Walter Brem, Los Angeles, for chairman, and Roy W. Hammack, Los Angeles, for secretary. These candidates were elected officers of the Section for the coming year. The scientific program consisted of symposium on "Coccidioidal Granuloma and Allied Infections." First paper by E. C. Dickson of San Francisco, "A Report of Cases With Especial Reference to Meningeal Involvement." Second paper by G. Y. Rusk of San Francisco, "Coccidioides Immitis as a Cause of Meningitis With Hydrocephalus." Third paper by Roy W. Hammack and J. M. Lacey of Los Angeles, "Cases Observed in Southern California."

Fourth paper by N. G. Evans of Loma Linda, "Torula Infection." These papers were discussed by Brem, Taylor, Ophuls, Dickson, Rusk, Hammack and Evans. Meeting adjourned at 4:30 p. m.

SECTION ON TECHNICAL SPECIALTIES

RAY LYMAN WILBUR, Chairman
HAZEL E. FURSCOTT, Acting Secretary

The first meeting of the Technical Specialties Section of the California Medical Society was held at Yosemite, California, May 5, 1922, 2 p. m. The chairman's address brought out the necessity for the general practitioner to be familiar with therapeutic agents other than medicine. The fields of physiotherapy, dietetics, laboratory technique, and social service have been long recognized as specific treatment in the care of the sick, but had become subordinate because of the unfortunately limited connotation of the word medicine. The physician should know how to use and prescribe in these fields, but he cannot be expected to learn all these technical branches. For that reason the technician must be trained. In physiotherapy adequate training is necessary to combat the credulity of the public in chiropractic and other cults. He pointed out the danger of the dietetic fanatic and encouraged the scientifically trained dietician to supplant the former. The relation of the home and social conditions of the patient he showed to be an important factor in the health program; he urged that the medical social worker be used to meet this need. Charles Pinkham, secretary, Board of Medical Examiners of the State of California, maintained that educated physiotherapists would be the solution of cultism. J. T. Watkins of San Francisco pointed out the dangers of the inadequately trained nurse in physiotherapy; referring to the situation and tendencies in this direction of certain organizations. Langnecker of San Francisco made a plea for the training of physicians to intelligently prescribe physiotherapy. Hazel Furscott emphasized the fact that the nursing profession prefers to keep its identity and is not interested in encroaching on the physiotherapy field except after adequate supplementary training. Edna Shirpser, secretary of the California Association of Medical Social Workers, thanked Dr. Wilbur for his interest in the medical social service and Florence Atkinson expressed the gratitude of the California Association of Physiotherapists. This discussion was followed by a business meeting for the election of officers for the ensuing year. Ray Lyman Wilbur was unanimously re-elected president, and C. LeRoy Lowman of Los Angeles, secretary.

THE CALIFORNIA ASSOCIATION OF PHYSIOTHERAPISTS

HAZEL E. FURSCOTT, President
FLORENCE E. ATKINSON, Secretary

The first annual meeting of the California Association of Physiotherapists was held May 17, 1922, 10 a. m. After preliminary remarks by the president, outlining the organization of this association, its activities during the past year, and its plan for future development, Ray Lyman Wilbur, in a thoughtful address on "Educational Standards in Physiotherapy," struck the keynote of the situation in his discussion of the fundamental and technical needs of scientific physiotherapy. The discussants, Morton Gibbons, E. W. Cleary, H. L. Langnecker and J. T. Watkins, felt that Dr. Wilbur had so adequately defined the needs of the situation that they could add nothing but their hearty commendation. The paper by A. W. Hewlett of Lane Hospital on "The Effect of Massage, Heat and Exercise on the Local Circulation," exemplified in detail the necessity for definite scientific research. Spiro in his discussion of Hewlet's paper brought out the point that the feeling of well-being was an important result of stimulation of the circulation. An informal discussion on "Early Physiotherapy Treatment of Fractures," led by Carl Hoag of the University of California Hospital, showed the advantage of different physical therapeutic agents. T. J. Watkins, Gibbons, Kapp, Gottlieb and Mabel Penfield agreed on the general advisability of the procedure. A suggestive point brought out by this discussion was the use of diathermic heat and electric stimulation during the period of immobilization in cast or splint. "The Standardization and Uses of Physiotherapy Equipment" was presented by Mahel Penfield, physiotherapy technician of San Francisco. Her paper contained a fund of detailed information useful to both physician and technician. In the discussion that followed Carl Hoag emphasized the importance of the personality of the physiotherapist over that of apparatus. George Evans of San Francisco stated that physiotherapy was now largely utilized by certain specialties of medicine. He made a plea for the enlargement of the physiotherapy activity to include the patients from all fields of medicine. Other discussants were Kapp and Gottlieb. Hazel E. Furscott, Physiotherapy Department, University of California Hospital, presented a paper on "Physiotherapy Records," illustrated by a complete set of measuring apparatus and lantern slides. The paper showed clearly that these records of progress furnish a definite encouragement of the patient, illustrates the responsibility of the technician to the physician, and establishes the value of physiotherapy records in the advancement of science. At the annual business meeting the following members were present: Hazel E. Furscott, Florence E. Atkinson, Mabel Penfield, Mary Schaaf, Florence Burrell, Sarah R. Davis, Laura McAllister. Acting on ideas for future development of physiotherapy set forth in Dr. Wilbur's address, a resolution was passed unanimously that this association form a committee to draw up a resolution expressing its desire to formulate and conduct an examination for a certificate of approval of this association for trained physiotherapists; the examination to be such as will be approved by a special committee of the State Medical Society, the object being to stimulate proper educational facilities for the training of future physiotherapists.

CALIFORNIA ASSOCIATION OF PHYSIOTHERAPISTS

President's Address

HAZEL E. FURSCOTT, San Francisco, California

It is, indeed, a great pleasure to call this first annual meeting of the California Association of Physiotherapists. The association was organized last May for the purpose of establishing and maintaining adequate standards in physiotherapy, and afford the members of the medical profession a group of educated, trained ethical technical assistants. At the present time we have forty-three active members and nine associate members. The most distinctive feature of the past year was a stimulating series of monthly scientific programs. In addition to the contributions by our own members it was our good fortune to have as speakers Doctors Naffziger, Pope, Cleary, Mehrtens, McChesney, Dudley Smith, Markel, Schaller, Tranter, and Hoag.

During the past year many problems have confronted us which we have endeavored to overcome. Outstanding among these were:

First — A gradually decreasing number of educated physiotherapists, due to the lack of adequate educational facilities.

Second—The discrimination in the selection of membership between the educated, trained, physiotherapist and the unethical pretenders.

Third—The need for correlation of existing data and for research.

To meet these needs a survey was planned and workers appointed to gather the necessary information on which to build a foundation for scientific progress.

First—To survey the schools of Europe and America, giving courses in physiotherapy or related subjects.

Second—To survey educational and practical conditions of physiotherapy in the state of California.

Third—To draw up a complete bibliography of physiotherapy literature.

It is the intention of our association to publish this survey when completed.

It would have been impossible to have carried through the past year without the co-operation and assistance of the officers of the Medical Society of California and the League for the Conservation of Public Health.

CALIFORNIA ASSOCIATION OF MEDICAL SOCIAL WORKERS

The first annual meeting was held May 17, 1922. Edna J. Shirpser presided. A paper on "Medical Social Service in the Hospital" was read by Marguerite Wales, director social service, Stanford Hospital. Ray Lyman Wilbur discussed "The Relationship of Social Service to the Medical Profession." "The Place of Medical Social Service in Hospital Organization and the Duties of Medical Social Workers Toward Hospital Administration" was the subject of a paper by Frank R. Nuzum, Cottage Hospital, Santa Barbara. The important subject of "Social and Economic Diagnosis" was discussed by C. H. Arnold, Stanford Hospital; F. R. Nuzum, Santa Barbara; Alvin Powell, Oakland; T. C. Lyster, Los Angeles; F. W. Hodgdon, Jr., Pasadena; Mrs. McManus, State Board of Health, and Marguerite Johnson, Telegraph Hill Clinic, San Francisco. At the business meeting Marguerite Wales was elected president, Josephine Abraham vice-president, Edna J. Shirpser secretary and treasurer for the ensuing year. The following directors were elected: Lillie Lindsay, Regina Horton, Eleanor Stockton and Rose Steinhart.

Stanford Establishes Course of Instruction for Physiotherapists—There has recently been instituted in Stanford University Hospital, a course of study for the training of technicians in physiotherapy. This course is designed to give adequate theoretical and practical knowledge to those persons who want to have efficient training in this branch of medical treatment carried on under the supervision of the medical profession. It is also open to members of the medical profession who may be interested in acquiring familiarity with the methods and results of the various forms of physiotherapy. The course has been instituted to meet a strong demand for wider universal knowledge of physiotherapy in its application to rehabilitation and industrial accident work.

COUNTY NEWS

ALAMEDA COUNTY

Alameda County Medical Association (reported by C. L. McVey, secretary)—The general meeting of the Alameda County Medical Association was held on June 19 at the Public Health Center.

S. Everingham read a paper, "Fractures—Their Early Treatment.' P. F. Abbott presented a case of Mikulicz's Disease. W. A. Wood and Ann Martin discussed the following subjects, "Clinical Importance of the Schick Test. Toxin, Anti-Toxin Treatment." The Ethel Moore Memorial Building of the Alameda County Health Center will be completed about August 1, 1922.

New Maternity Department for Fabiola Hospital—According to Mrs. J. P. H. Dunn, president of the Fabiola Hospital Association, a contract has been let for a new maternity department for Fabiola Hospital to cost $200,000. The maternity department is to be modern and complete in every respect and is to have fifty beds.

$700,000 Hospital for Oakland—The Providence Hospital Association has purchased the Bancroft Block in Oakland and the Sisters of Providence Hospital announce that they hope to begin the erection of the new $700,000 building this year. Nineteen years ago the Sisters of Providence Hospital Association came to Oakland and they have operated the present hospital since that date. Providence Hospital of Oakland is one of a chain of hospitals, extending through Canada, the Northwest, and south to Oakland, California. The Mother General is at the head of the main hospital in Montreal, Canada.

BUTTE COUNTY

Enloe Hospital, Chico—Dr. N. T. Enloe has again assumed charge of the management of the Enloe Hospital. Dr. N. T. Enloe, Jr., who has been managing the hospital for the past year, is devoting his entire time to the automobile business.

FRESNO COUNTY

Fresno County Hospital Accredited by Council on Education and Hospitals of A. M. A.—The Fresno County Hospital has been accredited for the instruction of intern in a letter of June 17 to Dr. H. O. Collins, director of the hospital. The letter reads in part as follows:

> "We are sure that you realize how much we are interested in the good work which the hospital is doing. It has been a pleasure to note from time to time the really important strides which have been made within the last few years as they have come to our attention from you directly and especially through the very thorough and conscientious work of Dr. Musgrave.
>
> "Along with our recognition of your hospital on our list of hospitals approved for internship there is an interest that will not be in any sense abated, and I assure you that the future progress of your hospital will be a matter of great interest to us and I hope to hear from you from time to time."

This accredited standing was made upon the recommendation of the Council's committee in California, which is the section on Medical Economics, Education and Hospitals on the League for the Conservation of Public Health.

Dinuba Sanitarium Sold—H. T. Haden has purchased the property of the Dinuba Sanitarium from Charles Weddel for $30,000.

Selma Sanitarium Now Open For Patients—A new sanitarium at Selma has at last been finished and is now operating. The Board of Directors are: O. W. Steinwand, secretary; Mrs. Maude Scott, treasurer; C. W. Christenson, J. P. Olsen and P. H. Hansen.

KERN COUNTY

Jefferson Hospital—Drs. Hawkins and Edgerton have opened a new hospital of twenty beds in Taft at Fourth and Lucard streets. Miss Nan Rector is superintendent of this new hospital. The basement of the building contains the nurses' quarters, kitchens, storerooms, etc., while the main floor is given over to patients' beds and office space. Drs. Hawkins and Edgerton state that their hospital is open to all physicians upon equal terms.

Kern County Hospital—It is reported that the Board of Supervisors of Kern County have purchased a site for the new County Hospital. Plans for the hospital, which with the new juvenile home and home for indigents will cost approximately $400,000, are now being drawn.

LOS ANGELES COUNTY

Barlow Sanitarium Receives Bequest—By the terms of the will of Mrs. Lucia W. Jennison of Covina, the Barlow Sanitarium was left a $5000 bequest as a memorial to her husband and son.

Golden State Hospital—J. Rollin French and C. E. Early operate this hospital in connection with their industrial, surgical and restoration institution. According to the Los Angeles Express this hospital has recently been very much enlarged and improved in many ways.

Hollywood Hospital—Architect Robert H. Orr has been commissioned to prepare plans for the new Hollywood hospital to be located on Vermont avenue near Sunset Boulevard. The Hollywood building is to be four stories and basement, covering an area of 8700 square feet.

Municipal Hospital for Long Beach—A meeting was held on July 11 of all persons interested in hospital work for the city of Long Beach. Long Beach has recently voted a bond issue authorizing the city to construct a hospital. Councilman Fillmore Condit, head of the City Hospital Committee, presided.

Ministers of Long Beach Request Service for Sick at Cost—A Long Beach Ministerial Union recently passed the following resolution:

"Whereas, It is customary in most Christian communities to provide hospital facilities for the sick and injured on a non-profit basis; and

"Whereas, A movement is on foot in Long Beach to make such a provision possible in this community;

"Resolved, that the Ministerial Union of Long Beach appeals to the Seaside Hospital Association to lead in the organization of a community hospital association upon a non-profit dividend basis to serve the interests of our city under a just and equitable recognition of the rights of the present owners of the Seaside Hospital property."

Harbor Hospital Association of San Pedro—The physicians of San Pedro are making an effort to build and operate a satisfactory hospital at San Pedro. Over $50,000 has already been subscribed and the association has $21,000 on deposit. The site has been purchased at Tenth and Meyler streets and the foundations are already under construction. The present board of directors is made up largely of Long Beach and Los Angeles stockholders. These stockholders have expressed their willingness to turn over to the San Pedro physicians their holdings as well as the management of the institution wherever San Pedro physicians are in a

position to accept the responsibilities. Dr. Rodgers of San Pedro is taking a leading part in the activities of this hospital.

Murphy Memorial Hospital—The Forum Club of Whittier recently held a meeting to discuss the future of the Murphy Memorial Hospital. This hospital, originally constructed by Colonel Murphy, was donated to the municipality of Whittier under certain conditions.

Permanent Quarters—Harlan Shoemaker, secretary of the Los Angeles County Medical Society, reports progress with their permanent building fund. This is a most worthy movement which should have the endorsement and support of all members.

Barlow Library Notes—Barlow Library is maintained by the medical profession. Our own people pay the bills! You are welcome to use it, without money and without price. But a ten-dollar or a twenty-five-dollar membership is appreciated. If you wish to become a member send your check to the librarian, and watch the results. Try it once, anyway.—(L. A. Med. Soc. Bulletin.)

Cottage Hospital, Burbank—Miss Cecil Williams, former owner of the Cottage Hospital, has sold it to Miss Grady Weems, Miss F. Short and Miss Beulah Newton. Miss Weems is the superintendent, Miss Short will be in charge of the surgical department and Miss Newton will act as superintendent of nurses.

Lamanda Park Hospital—Dr. J. B. Keaster has purchased the property at 2563 East Colorado St., and is converting the present building into a hospital of which he is the owner and director.

New Hospital for Torrance—A bequest of $100,000 was left in the will of the late Mr. Torrance for the erection of a hospital at Torrance, the town which he founded. The details of the bequest have not yet been made public.

Additions to St. Vincent's Hospital—The Sisters have decided to build an annex to cost $300,000 to St. Vincent's Hospital. Mr. J. S. Austin, architect, states that the annex will be eight stories high and contain one hundred beds.

Culver City Hospital—F. M. Hull, M. D., will shortly erect a five-bed hospital on Putnam avenue. The new hospital will be provided with laboratory and X-ray equipment.

MARIN COUNTY

Marin County Medical Society (reported by Chester A. De Lancey, secretary)—At the last meeting of the Marin County Medical Society it was voted to take under consideration the questionnaire concerning industrial medicine. This action was taken in order to gain further information on this subject which it is expected will appear in an article in the State Journal of Medicine.

Arthur Mays, who was a delegate to the State convention, gave an interesting account to a special meeting of the society of the different meetings at Yosemite.

Hans Lisser of San Francisco favored the society with an address on Endocrinology. He pointed out that pluriglandular therapy is useful only when constructed on monoglandular therapy in given individual cases. He also pointed out the necessity of telling patients at the outset that glandular therapy extends over many months. Many new and interesting points on endocrinology were presented to the society.

San Rafael Cottage Hospital—The San Rafael Cottage Hospital is reported to be installing a delivery room for the maternity department.

MONTEREY COUNTY

Monterey Sanitarium—Dr. Martin McAulay has converted the old Governor Pacheco adobe residence into a hospital, equipped with operating room, X-ray and other departments.

NAPA COUNTY

Walter Springs Health Resort Sold—The Walter Springs Health Resort, controlling the output of the Walter Springs Water, has been sold to Mr. Van Hovenberg of San Francisco. Mr. Van Hovenberg proposes to make this one of the attractive resorts of California.

ORANGE COUNTY

Orange County Medical Society (reported by Rowland P. Yeagle, secretary)—At the regular meeting of the society for April, held in Santa Ana, the following officers were elected for the ensuing year: President, James C. Crawford, Orange; vice-president, Bessica F. Raiche, Anaheim; treasurer, William C. Duboid, Santa Ana; secretary, Rowland P. Yeagle, Santa Ana; librarian, John Wehrly, Santa Ana; board of councilors, J. H. Lang, Fullerton, G. A. Shank, Huntington Beach, C. D. Ball, Santa Ana.

Orange County Hospital To Have Addition—Plans are under way to build a psychopathic ward in connection with the Orange County Hospital. The new addition will cost $28,000. H. E. Zaiser, M. D., director of the hospital, states that the new department will be made as free from any appearance of restriction as it is possible to make it. A courtroom will be provided in connection with the addition.

PLACER COUNTY

Placer County Medical Society (reported by Robert A. Peers, secretary)—The Placer County Medical Society met in Auburn, at the Masonic Temple, July 8, 1922. Charles J. Durand, the president of the society, occupied the chair. The following members and visitors were present: Members—Drs. Durand, Miner, Peers, Rooney, Mackay, Fay, Talbot, Horne and Russell. Visitors—Wiltse, Auburn; Kanner, Colfax; Whittington, Weimar; Ward, Auburn.

H. M. Kanner of Colfax, Dwight Davis Johnson of Grass Valley and William L. Whittington of Weimar, a member of the Alameda County Medical Society, were elected to membership in the society.

The following members were endorsed for industrial insurance work—W. P. Sawyer, Nevada City; J. Gordon Mackay, Auburn; J. A. Russell, Auburn; William A. Lavery, Loyalton; George Howard Fay, Auburn; A. H. Tickell, Nevada City; E. R. Brooks, Floriston; Frank Lisle Horne, Auburn; Earl E. Ostrum, Loomis; J. Suley Wheeler, Lincoln.

Case reports were made by the following members: Miner, Kanner, Mackay, Talbot, Rooney, Peers and Whittington.

Robert F. Rooney of Auburn read the paper of the evening entitled "Over Fifty Years in Medicine," in which he traced the history of medical discoveries during his fifty-two years of practice. The doctor also spoke of his many personal experiences during this time. He also paid his respects to the various cults and fads of that period. He finished by reciting a poem, written by himself, entitled "The Old Practitioner." Rooney's paper was enthusiastically received and was discussed by all those present. The remainder of the evening was spent in reminiscences.

PLUMAS COUNTY

New Sanitarium at Quincy—Dr. W. W. Peterson is constructing a sanitarium at Quincy. Dr. Peterson will have charge of the Feather River Lumber Producers' Association practice.

RIVERSIDE COUNTY

Riverside Community Hospital, Election of Board of Directors—At the annual meeting of the Riverside Community Hospital Association the following directors were elected for the ensuing

year: W. B. Clancy, Mrs. George Cole, E. M. Doyle, Lyman Evans, S. C. Evans, T. F. Flaherty, J. T. Garner, Stanley F. Henshaw, Rev. R. A. Kirchoffer, Alfred M. Lewis, Frank A. Miller, F. T. Morrison, Mrs. Julia Moulton, Mrs. A. N. Sweet, A. B. West. The annual report of the Secretary showed the subscriptions towards the new hospital $189,519.26, subscribed by 2,314 persons.

New Medical Director of the Riverside County Hospital—Dr. W. A. Jones of Arlington has been appointed. Dr. E. H. Wood, former director, has had to give up the work for the present on account of ill health. Miss Jessie Twogood will continue to act as head nurse and Mrs. Margaret Carroll as housekeeper and business manager.

Hillcrest Hospital Has New Director—Dr. J. A. Ramsay will be general manager and chief physician to Hillcrest Hospital, Hemet. Dr. Gregory, former director of the hospital, has retired from its active management.

SACRAMENTO COUNTY

Sutter Hospital—I. W. James, M. D., Secretary of the Board of Directors, announces that the contract for the construction of the new Sutter Hospital has been awarded to George Wagner of San Francisco. The hospital is to be located on L Street between Twenty-eighth and Twenty-ninth Streets.

SAN BERNARDINO COUNTY

Upland Hospital (Paul Memorial Hospital)—At the annual meeting of the board of directors of this hospital held recently, E. W. Paul was elected president; E. H. Richardson, vice-president; Thomas W. Nisbet, secretary; Harold C. Moore, treasurer. Other directors are: Dr. W. H. Craig, Mrs. James L. Paul, G. A. Hanson, W. K. Beattie, Dr. J. H. Titus and A. H. Johnson. Plans for this new hospital, which is to cost $110,000, have at last been approved, and there is a campaign on at the present time to increase the funds on hand sufficiently to open the institution without debt.

SAN DIEGO COUNTY

San Diego County Medical Society (reported by Robert Pollock)—The San Diego County Society will hold no scientific sessions during July and August. It plans to promote goodfellowship preliminary to the fall sessions by holding a picnic for the members and their families late in August. The prevailing epidemic in San Diego and vicinity at present seems to be acute polydipsic golfitis. No fatalities have as yet been reported, although restrictive measures are contemplated by the authorities. The County Society tendered a banquet to Ernest Fuchs of Vienna during his brief stay in San Diego while enroute to San Francisco, where he delivers a course of lectures on opthalmology. Dr. Fuchs' address was replete with practical diagnostic points related to every-day eye conditions that confront the general practitioner.

Alpine Sanitarium Under New Management—Paul M. Carrington, M. D., has taken over the management of the Alpine Sanatarium at Alpine, San Diego County, and will continue it as an open-staff hospital. Its location admirably fits it for the treatment of the tuberculous and asthmatic as well as those suffering from nervous and nutritional disorders.

Addition to Paradise Valley Sanitarium—About 500 people attended the laying of the cornerstone of a new 50-bed addition to the Paradise Valley Sanitarium at National City on the afternoon of July 2. The exercises were presided over by Alton D. Butterfield, medical director of the institution, and the address of the day was delivered by Percy T. Magan of Los Angeles, member of the hospital betterment committee of the League for the Conservation of Public Health for Southern California. The new building will be of fireproof construction, and will be devoted to surgery and obstetrics.

Proposed Escondido Cancer Hospital—It is reported that Dr. L. T. A. Hotten of Escondido has asked permission of the city trustees to solicit funds to build and operate a cancer hospital at Escondido. It is further reported that the board referred the matter to Dr. Lorini, Health Officer, for recommendation, and that Dr. Lorini gave his consent for the soliciting of funds for the hospital from the public.

SAN FRANCISCO COUNTY

San Francisco Board of Health Replies to Criticism of the San Francisco Hospital—The Board of Health takes exception to the reported statement of the foreman of the grand jury that "deplorable conditions" exist at the San Francisco Hospital and that "poor patients are miserably treated." In an open letter, President Barendt says:

"In a large institution such as the hospital, there cannot help but be occasional infractions of the rules by some of the employes, visiting or attendant physicians, but to condemn an entire institution for the infraction of a rule shows the utter unfitness of the critic in this case to occupy the position which he does.

"I have been unable to find that any of the grand jury for whom Jungblut professes to speak have visited the hospital or have mentioned to anybody in what the 'deplorable state of affairs' consists.

"I have only to invite the members of the grand jury to visit the hospital whenever they please and —with due regard to the feelings of the patients— to make their rounds wholly unattended and to investigate it from garret to basement."

SANTA BARBARA COUNTY

Celite Hospital Destroyed by Fire—On May 25, at one o'clock in the morning, Celite Hospital at Lompoc was discovered to be on fire and very quickly burned. No lives were lost. Mr. Smith, the superintendent, states that it will be reconstructed.

SANTA CLARA COUNTY

East Columbia Hospital, San Jose, Has New Director—Dr. Frank H. Paterson has turned the management of the East Columbia Hospital over to H. D. Jenkins. According to newspaper dispatches Jenkins plans to make a number of improvements in the physical plant and is quoted as saying that the future of the hospital is to be built upon two words, "service" and "business."

San Jose Physicians Form Luncheon Club—The physicians of San Jose have formed a luncheon club to meet every Tuesday. H. C. Brown is president and R. S. Kneeshaw secretary of the club. It is proposed to have prominent guests attend as many as possible of these meetings, to discuss matters of interest to physicians.

SISKIYOU COUNTY

Siskiyou County Abandons Plan for County Hospital—Supervisors of Siskiyou County had plans plans well under way for construction of a $200,000 hospital, to be located at Yreka. A delegation of taxpayers appeared before the supervisors to demand that all plans be abandoned. The supervisors decided to do so for the present.

SOLANO COUNTY

Vallejo General Hospital—This new hospital is located at the corner of Tennessee and Sutter Streets in Vallejo and is now open for patients.

SONOMA COUNTY

Sonoma County Hospital—Plans are under way for the erection of a department to the Sonoma County Hospital for the care of patients suffering from tuberculosis. The plans were advanced at a meeting held in the offices of Dr. P. A. Meneray for the discussion of problems connected with this work.

Hillside Hospital—This Hospital, located at Petaluma, has been sold to Carl Haderman, who will take immediate possession. Mrs. Johanna Petersen will be superintendent. Mr. Haderman states that he will continue to run the hospital as a first-class institution.

STANISLAUS COUNTY

Oakdale Hospital—The municipal board of trustees of the proposed Oakdale Hospital has been organized. The directors are: E. T. Gobin as president of the board and R. L. Acker as secretary; the other members are A. L. Gilbert, Mary Roberts, Ed Rodden, Mary Lambuth, W. A. Patterson and L. C. Kaufman. The board decided to build a sixteen to twenty-bed hospital, two stories high, at a cost not to exceed $30,000 for building and equipment.

Temporary Hospital—Physicians of Oakdale have joined in establishing a temporary hospital in a home, pending the completion of the proposed municipal hospital. The dwelling being used for temporary purposes is being improved and will take care of five patients when ready for occupancy.

TULARE COUNTY

Instructions for Mothers in Hygiene at Dinuba—Newspapers report that the Dinuba Chapter of the Red Cross, under the leadership of one of their school nurses, is planning to give a course of instruction in hygiene to the mothers of Dinuba. Mothers who take 18 hours of the instruction will be given a certificate.

VENTURA COUNTY

St. John's Hospital Organizes a Staff—The staff of St. John's Hospital, Oxnard, has been organized, with the following officers: John G. Norman, president, and Raymond T. Francis vice-president and secretary. The staff is to meet once a month.

YOLO COUNTY

Tuberculosis Survey in Yolo County—It is reported that a public health nurse is arranging for a tuberculosis survey of Yolo County and that she will call in expert assistance from outside to assist her in making examinations and tests. According to newspaper reports, the object is not so much to acquire statistics as it is "to assist those who are tubercular or showing signs of the dread disease in combating it in its early stages."

Is it possible that the physicians of Yolo County are not essential in making diagnoses or giving treatment to tuberculous patients in that county?

Printer Was Peeved—A printer in Fort Worth, Texas, got slightly peeved at a letter from a doctor who wanted bids on several thousand letterheads, different sizes, different grades, and different colors, and wanted the printing form held standing. So he took his typewriter in hand and wrote:

"Am in the market for bids for one operation for appendicitis. One, two or five-inch incision—with or without ether—also with or without nurse. If appendix is found to be sound, want quotation to include putting same back and cancel order. If removed successfully, bidder is expected to hold incision open for about 60 days, as I expect to be in the market for an operation for gallstones at that time and want to save the extra cost of cutting."—Kansas City Post.

SOME GOOD LEGAL ADVICE

Mr. George W. Whiteside, attorney N. Y. Medical Society, in New York Medical Journal, offers some good legal advice to physicians:

"Use X-ray in diagnosis of all fractures and dislocations both before and after the fracture or dislocation is reduced. The X-ray plate provides a permanent record of the condition and reduces the element of possible fraud upon the physician. In orthopedic work often ordinary photographs of conditions that would not be indicated by the X-ray are likewise of value.

"Where a physician is dismissed from a case, a letter to the patient, the physician retaining a carbon copy, fixing the time and circumstances, might prevent a future claim by the patient that the physician abandoned the case. This claim by patients has arisen in a number of cases, where the true facts clearly indicated that the physician was dismissed and another physician employed.

"In cases of children particularly, although clinical diagnosis may not indicate diptheria cultures from the nose and throat should early be taken. Suits have been based upon the claim that such cultures were not taken, where fortunately the physician was able to show from the records of the Department of Health the taking of such cultures.

"Where diphtheria is present in one child in a family, similar cultures may well be made of the other children and members of the family. This practice should at least be advised by the physician to the family, and while of doubtless benefit to the family as a precautionary measure, may eliminate and prevent the probability of claims against a physician.

"The early use of antitoxin in all diphtheria cases in doses suggested by the health authorities is recommended.

"Where intubation is necessary, insist that the patient be in charge of a nurse competent to act when conditions indicate the necessity of reintubation, so that intubationists may be summoned promptly. In the absence of such expert nurse advise hospital treatment.

"Advise either patient or family of the probable outcome of disease or operation where feasible. This may avoid claims against a physician where unsatisfactory results are inevitable in the nature of the case, but, through patient's ignorance or otherwise, claims against a physician are made.

"Time and frequency of visitation to sick patients in serious cases should be determined by the physician and not by the family. A doctor's desire to save a patient expense may be considerate for the patient's purse, but may be hazardous to the doctor if subsequent claim of neglect of the case is made.

"Keep records of every patient treated so that the transaction may be identified. Records made at the time of treatment may be invaluable to the physician in establishing the falsity of the claim made against him."

Resolution Disapproving the Public Health Activities of the Red Cross—"We approve the recommendation of the Board of Trustees relative to the Public Health activities of the American Red Cross, and their advice that the House of Delegates take appropriate action to convince those in authority that the public health activities of this organization are no longer necessary, and if continued are likely to promote community irresponsibility and helplessness in regard to its own welfare.

"Your committee further recommends that the Board of Trustees take such action as will make this recommendation effective at the earliest possible moment."—Abstract from Minutes of the Seventy-Third Annual Session of the A. M. A.

BOOKS RECEIVED

Transactions of the American Pediatric Society. Thirty-third session. Held at Swampscott, Mass., June, 1921. Edited by Joseph Brennemann, M. D.

Applied Chemistry. An elementary text book for secondary schools. By Fredus N. Peters, Ph. D., Instructor in Chemistry in Central High School, Kansas City, Mo., for twenty-three years; more recently vice-principal. Author of "Chemistry for Nurses," etc. Illustrated. St. Louis. C. V. Mosby Company, 1922. Price, $3.50.

Symptoms of Visceral Disease. A study of the vegetative nervous system in its relationship to clinical medicine. By Francis Marion Pottenger, A. M., M. D., LL. D., F. A. C. P., Medical Director Pottenger Sanitarium for Diseases of the Lungs and Throat, Monrovia, California. Author of "Clinical Tuberculosis," "Tuberculin in Diagnosis and Treatment," "Muscle Spasms and Degeneration," etc. Second edition. With 86 test illustrations and 10 color plates. St. Louis, C. V. Mosby Company, 1922. Price, $5.50.

The Healthy Baby. The Care and feeding of infants in sickness and health. By Roger H. Dennett, B. S., M. D., Professor of Diseases of Children and Director of the Department in the New York Post-Graduate Medical School; attending physician in the Babies' Ward of the New York Post-Graduate Hospital; Consulting Pediatrician to the Victory Memorial Hospital, Brooklyn, the Passaic General Hospital, the New York Episcopal Orphans' Home and Asylum, etc.; Fellow of the New York Academy of Medicine. Second edition, revised. New York, the MacMillan Company, 1922. All rights reserved.

BOOK REVIEWS

Diseases of the Eye. A handbook of ophthalmic practice for students and practitioners. By George E. de Schweinitz, M. D., LL. D. Ninth edition, reset, with 415 illustrations and seven colored plates. Philadelphia and London: W. B. Saunders Company, 1921.

Many new subjects, including new operative procedures, make their first appearance in this edition. This standard textbook reflects the present state of the knowledge and the literature of ophthalmology. F. C. C.

Diseases of the Skin and the Eruptive Fevers. By Jay F. Schamberg, M. D., Professor of Dermatology and Syphilis, Graduate School of Medicine, University of Pennsylvania. Fourth edition thoroughly revised. Octavo of 626 pages, 265 illustrations. Philadelphia and London: W. B. Saunders Company, 1921. Cloth, $5 net.

This book is well worth the room and its purchase price. The discussions on syphilis and the eruptive fevers particularly are diagnostic and among the best. The book contains many excellent prescripions.

In most of the ordinary skin diseases the descriptions are quite concise and well worth reading. The reviewer recommends the book. G. D.C.

Opportunities for Malpractice Suits—"A suit for malpractice may be based on acts of omission as well as commission, and a physician may be sued for failing to do something he should have done as well as for doing something he should not have done. Another definition says, "Malpractice is the treatment of a patient by a physician or surgeon in a manner contrary to accepted rules and with injurious results to the patient." Every courageous physician who advances further than the accepted rules permit may lay himself liable to a charge of malpractice.

It is definitely known that in a large majority of the malpractice suits the patient was unable to and did not pay for the services rendered by the physician. The reasons why charity patients are more prone to bring malpractice suits are, first, these patients are notoriously careless and indifferent about following the advice and instruction of the medical attendant; and second, they always need the money. They are just as careless about following instructions regarding a fracture as they are about their financial affairs and, therefore, they are more likely to get a bad result. Because they always need money they are usually willing to sue a physician, or anyone else for that matter, if there is even a faint chance to obtain money.

Young impecunious lawyers are frequently a cause of malpractice suits. The old-established lawyer of good reputation very seldom appears for the plaintiff in a malpractice suit against a physician. He has acquired a wholesome respect for the medical profession and his observation has taught him that it is very seldom that a medical practitioner is actually guilty of malpractice.

I have known of a few suits that were brought because of the jealousy and meanness of a rival practitioner of medicine. Of all asinine, stupid ways of getting revenge, the instigating of a malpractice suit is the meanest. If the suit is successful it will probably encourage others, and the star medical witness for the plaintiff is likely to be the defendant in the next case."—Illinois Medical Journal, June, 1922.

The Cost of Medical Insurance in England—Sir J. D. Rees, M. P., recently stated "that the expenditure in this connection had risen from twenty-five millions sterling in 1890-91 to three hundred and thirty-two millions in 1920-21 and would probably be not less than four hundred millions for 1921-22. He developed the fact that thirty million persons, exclusive of unemployed, out of a population of forty-eight millions, had been in receipt of public assistance in 1919-20. . . . . Mr. Macquisten pictured the application of the principle of the National Insurance Act to the legal profession and said that he imagined that if the public were required to 'hand over so much a week to the barrister for the purpose of getting advice, the legal advice obtained in such circumstances would be the same kind of advice as the medical advice given by the panel doctor.' This member evidently does not think very highly of the panel doctor nor of the act, which he said provided doctors who could not get practices in the ordinary competition in the medical profession and is carried on by inflicting penalties upon very poor people who can get no benefit from it. . . . An inquiry in Parliament, by Sir J. D. Rees, brought out the fact that the total charge upon the Government for health insurance in 1920-21 was approximately nine and one-half pounds and for 1921-22 estimated at nine million pounds. The contributions of employers and employed in 1920-21 were approximately twenty-one million four hundred thousand pounds, and estimated for 1921-22 at two hundred thousand pounds more than in the preceding year."

REFLECTIONS ON MEDICAL ETHICS

"Since nation-wide publicity, reaching to every obscure crossroads newspaper in the land, has been given to a speech delivered a few days ago by that otherwise useful man, Royal S. Copeland, reflecting on Medical Ethics, it is time for the profession to take notice. . . . When a man like Copeland gives voice to such statements as 'the Code of Medical Ethics is the most antiquated, moss covered germ ladened institution in the world' . . . . by his own language convicts himself of what it is charity to ascribe to simple ignorance on the part of its author. . . .

"No! the most emphatic tenets of medical ethics have always been to gladly and freely hand to humanity whatever has been discovered for the alleviation or cure of diseases and to condemn, as despicable quacks, all 'who make a secret of cures.' . . .

"Heritages from the wise, as well as the written evidences of lofty ideals from our profession, who during the ages have held aloft the Caducieus of Hermes, are sometimes overlooked in the cares and drudgery of professional life. Some, therefore, are to be found with heads more or less burdened with scientific acumen who show unpardonable ignorance of their duty to the community and to the profession to which they belong. Such one-sided tendencies can but be deplored. . . .

"The lamented Dr. Osler said in reference to the public: 'There is a delightful Arabian proverb, two lines of which run: "He that knows not and knows not that he knows not is a fool—shun him. He that knows not and knows that he knows not is simple—teach him." It is our province to have to deal with the extremes of civic life. We must fight the wilful ignorance of the other. Not with the sword of righteous indignation, but with the skilful weapon of the tongue. On this ignorance the charlatan and the quack live.' . . . It is unprofessional and ignoble to fail to defend the reputation of an absent brother when justice demands it—well has it been observed: 'He who degrades a colleague degrades his art.'

"In changing from one physician to another it is common for patients to attempt to justify their course by speaking ill of the former physician. No physician should permit such criticism.

"The porcupine attitude towards other physicans and petty quibbling only furnish material for jocose remarks from the public and add nothing to a vocation which holds a sacred trust. . . . Disparaging allusion to the ignorance of the past does not commend one, for the world knows centuries were required to produce one Hypocrates, a Jenner, a Pasteur and a Sims, not to mention a few great now living, and that the vaunted perfections of today will be viewed by the medicine of the future much as we contemplate prehistorc man's stone ax. . . . From the physician the public has a right to exact efficiency in diagnosis, treatment, and prophylaxis. To meet these requirements every available aid must be invoked to properly interpret the intricate symptoms at times encountered, not forgetting that abstract science is nothing unless it be the handmaiden to an analytical mind, common sense and sound judgment. . . . The crucial test for all conduct—the one law, which, regardless of creed or religion, all philosophers and prophets acknowledge as paramount in determining and governing human relationships from a social or economical viewpoint—is the Golden Rule. Make it the standard of measurement for every act; the court of last resort—the final tribunal for every doubtful position, and error will not occur."—Furman, Southern Medicine and Surgery, June, 1922.

GENIUS AT BAY

"If genius is a neurosis, as has been plausibly argued, then some interesting questions may be postulated in the light of new knowledge in the psychologic sphere.

"Hitherto, the genius either did not know that there was anything the matter with him, or if he suspected that there was he had no idea as to its nature. Other people said that his gifts were from God—or from the devil. But nowadays we account for him with equal glibness, in another way; we say that he is a neurotic, and we furnish him with a set of Freudian complexes that would put an Œdipus to shame.

"Now we don't believe that geniuses of an older day tried to understand themselves; they just pegged away at their marvelous creations and made the most of life without inquiring too closely into the reasons why of their unconventional activities; and it wouldn't have done them any good if they had, for men had not then gone beyond God and the devil in their thinking; Freud was born late, and our ancient geniuses were deprived, as it were, of his services.

"The point to which we are leading up is this: The genius of today can hardly escape 'contamination' by the Freudian lore which drips from everybody's tongue and pen. Will it not prove to be a tanglefoot influence? When your genius becomes self-conscious and censorious about his mechanisms will he not cease to be an honest-to-goodness genius? How can a potential Shelley, wrastlin' with something on the Skylark order, forget his complexes long enough to turn out an ode of immortal quality? Let us suppose that he starts in with an inspired line or two comparable to those with which Keats begins the Grecian Urn; at that point Keats was no longer a man, but a veritable god; at that same point our present-day genius will realize that it is only some darned homosexual complex that is attempting to order his fancies and he will not be able to capitulate to it quite completely enough to give us another another Grecian Urn?

"That is the point. How can there ever be another Grecian Urn?

"This Freudian stuff defeats that which it attempts to elucidate. It is a Frankenstein. It hampers the divine fermentation that begets great art.

"Suppose that Leonardo da Vinci had understood that his mother-love complex was at the bottom of all his extraordinary mechanisms, and suppose that he had realized all the morbidness and abnormality of his obsession—is it likely that he would have yielded to it so completely as to achieve all that we know as the product of his brain and hand? Do not such things depend, after all, upon one's sublime unconsciousness of the workings of creative mechanisms?

"Truly our civilization seems to carry within itself all the germs making for its own destruction.

"Today we understand the reasons for everything—which may be why we are at such a standstill in the world of art.

"It would require a genius to show us the way out of such a dilemma. How can the reductio ad absurdum be escaped?"—(New York Medical Journal, July, 1922.)

Sheppard-Towner Act Rejected—The Legislatures of Massachusetts and New York and Rhode Island have recently rejected Federal aid as offered through the provisions of the Sheppard-Towner act. New York has appropriated $130,000 for "protection of the health of mothers, infants and children" to be expended by their own Board of Health.

Legal Defense Indemnity in Malpractice Suits—"Dr. McDavitt, special committee chairman, Board of Trustees of the A. M. A., presented a report which embodied the study made by the committee of legal defense indemnity in malpractice suits. Emphasis was made of the need of co-operation between the administrative directors at headquarters of the Association and the committees on medical defense of the constituent State associations. Attention was called to the action of the Council on Health and Public Instruction in its report to the House of Delegates recommending the separation of all legislative functions from the jurisdiction of the Council. Inasmuch as the House of Delegates approved of this request of the Council on Health and Public Instruction and recommended the organization and establishment at headquarters of a Bureau on Legal Medicine and Legislation with a full-time secretary in charge, the Board empowered the Executive Committee and the General Manager to proceed at once with this undertaking."—Jour. A. M. A., June 10, 1922, p. 1821.

OBITUARY

THOMAS J. COX

Thomas J. Cox of Sacramento, one of the best known and best beloved physicians of this state, died suddenly at his home in Sacramento on July 5. Doctor Cox was born on the old-time Cox ranch on the American River fifty years ago. He was educated in the public schools of California and received his medical degree from Cooper Medical College of San Francisco. In commenting upon Doctor Cox's untimely death, the Sacramento Bee says:

"Deceased was a man of great public spirit, kindly disposition and generous heart. He was ever to the front in everything that made for public good, and for public weal, and for public advancement. His purse was never closed to the appeal of suffering or of want."

Doctor Cox leaves a wife and five children—three daughters and two sons; also a sister, Mrs. James Beach of Fair Oaks.

DEATHS

Jamison, William R. Died in Watsonville, Calif., June 29, 1922, aged 65 years. Dr. Jamison was a graduate of the California Medical College, 1895, and was a member of the California State Medical Society.

Herrick, Albert B., Sr. Died in Santa Rosa, Calif., June 27, 1922, aged 71. Graduate of Medical Department, University of Michigan, June, 1879. Deceased was the father of Albert B. Herrick, Jr., also a physician of Santa Rosa.

Diggins, Edward A. Died at Weimar Hospital, June 29, 1922. Graduate of Cooper Medical College in 1895. Dr. Diggins was a veteran of the Spanish-American and World wars.

Meigs, J. J. Died in San Francisco, July 8, 1922, aged 84. He received his degree of doctor of medicine from Harvard Medical School in 1860. Dr. Meigs was prominent in Grand Army circles, having been present at Appomattox when Lee surrendered to Grant.

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL *is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.*

RECENT DEVELOPMENTS IN RADIOTHERAPY.*

By REX DUNCAN, M. D., Los Angeles, Cal.
(From the Radium and Oncologic Institute.)

Radiotherapy, or the treatment of diseases by means of radiation, is based upon the fact that certain histological and bio-chemical changes are produced in the body tissues by rays capable of penetrating the tissues. This effect varies with the character, quality and quantity of radiation applied, and may be stimulating or destructive. All tissues are affected, but there is a hypersusceptibility of neoplastic or newly formed tissues. Generally speaking, the resistance is greater the more nearly the newly formed tissues histologically resemble normal, and a proportionately greater susceptibility in the more rapid growing and less perfectly formed types. However, a wide variation in susceptibility of tissues has been noted by all careful observers, and was further demonstrated by careful research conducted by Wood, demonstrating quite conclusively that it is impossible to establish a so-called lethal dose for cancer.

The histological changes that occur have been carefully studied by ourselves and numerous observers. We have, for some time, been grading our tumors according to the grouping suggested by A. C. Broders, and noting their susceptibility. This work, which will be published in detail later, gives a more comprehensive understanding of the biological effect of irradiation and suggests certain improvements in technique and the possibility of a more definite prognosis. The precise cause of these histological changes due to irradiation has not been determined. Whether or not it is due to the direct effect of the radiation on the neoplastic elements or secondary to the changes produced in the normal tissues, or a systemic effect or a combination of these and other changes, is a matter for further research. That destructive changes do occur in certain types of neoplasms consistent with the dosage and technique employed, is a well-established fact.

The rapid development and excellent results obtained with radium therapy have been due largely to the fact that with radium we possess a constant and definite source of energy and a very thorough understanding of its physical properties. The mechanical and physical problems of X-ray equipment have recently been developed to the point where we now have equipment, both machines and tubes, capable of operating under high voltage, and means of accurately measuring at all times the voltage employed. The character and quality of X-rays produced are dependent upon the voltage passing through the X-ray tube. The greater the voltage employed, the larger quantity of short-wave length or more highly penetrating rays produced, the intensity increasing as the square of the voltage.

Modern deep X-ray therapy has been made possible by the physicist and electrical engineer, who, through scientific research, have given us, first, Roentgen ray tubes, which will stand very high voltage continuously, and, second, the development of electrical apparatus which would generate safely high voltages with great reliability and safety from breakdown, and, third, physical measurements which enable us with certain technique to know quite accurately the character and quantity of radiation, and the percentage and distribution of intensity at various depths within the body.

The several factors governing the quantity and quality of the therapuetic application of X-rays are the type of equipment employed, the voltage, milamperage, screen or filter, skin distance, port of entry and time. Varying these factors, Dessauer, by elaborate physical researches, compiled

* Read before the New Mexico Medical Society, April 28, 1922, at Gallup, New Mexico; also before the California State Medical Society, at Yosemite, May 15, 1922.

certain tables, showing the distribution of intensity or intensity curves at various depths within the body.

Table 1 is based upon research of Dessauer and Coolidge, and is applicable to our equipment and technique, and shows, with various voltages, the percentage of intensity absorbed superficially or within the first cm. of tissue and that reaching 10 cm. in depth after filtering through from 0.5 mm. to 1.33 mm. of copper, employing a 25 cm. port and 50 cm. skin distance.

The biological or therapeutic value of deep X-ray therapy is dependent upon our ability to produce a sufficient and homogenous radiation of deep tissues, without destruction of the skin and intervening areas, and without too great toxaemia or systemic effect. The amount of systemic radiation is proportionately diminished with higher voltage, heavy screening and a lesser number of ports employed.

Figures 2 and 3 represent Dessauer charts, showing the curves and percentage of intensity at various tissue depths, employing 150,000 volts and 200,000 volts, and other factors as shown. The distribution of intensity with various voltages up to 300,000 volts under conditions practical for their therapeutic application, have been worked out principally by Dessauer, Coolidge and Wilson. With the necessary apparatus and the proper application of these physical facts, it is possible to evolve a technique by means of which the desired amount of radiation may be placed at practically any point within the body.

In our work we have found it most satisfactory to measure or calibrate the patient and draw on a piece of glass, film or transparent paper, a cross-section of the patient, outlining accurately as previously determined by examination, the areas of involvement and probable metastasis or extension of the disease. It is then possible to work out a technique of treatment that will enable us to apply the desired percentage of intensity to each area, and properly record same. While this requires considerable work in each case, it permits of a very accurate and scientific radiation, and prevents routine methods with their pernicious faults. The exact dosage and technique must be based upon the general physical condition of the patient, character and location of the involvement, and the histopathology of the neoplasm.

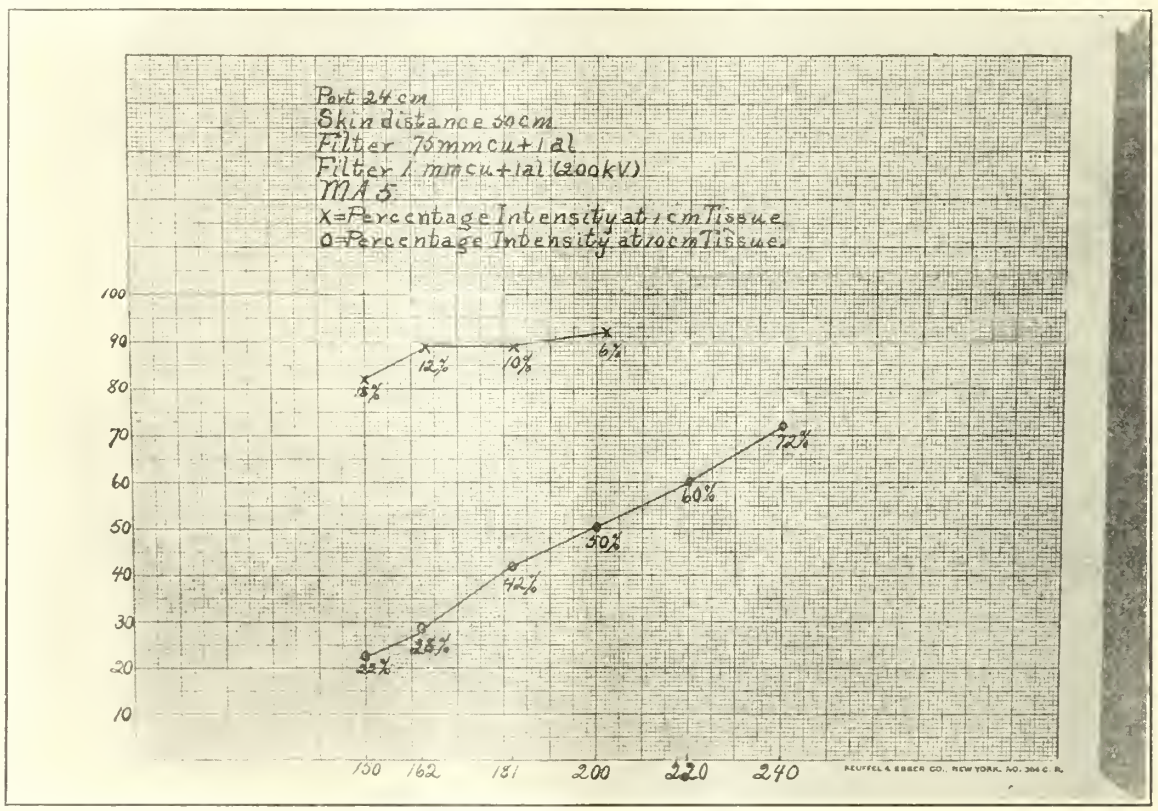

Figure 1

Clinical and experimental observations of the effect of deep X-ray upon the constituents of the blood show diminution in red cells, with corresponding reduction in hemoglobin. For several hours following irradiation there is a neutrophilic leukocytosis, followed by a leukopenia, with particularly striking diminution in the number of lymphocytes. Cases with a marked anemia should not be subjected to vigorous X-ray treatment until the blood picture has been improved.

The biological dosage of X-ray is dependent upon many factors previously referred to, and will require extensive observation and research.

The actual technique as employed in the European clinics varies greatly. There is, however, an unanimity of opinion on two essentials for intensive X-ray therapy; apparatus which can deliver at least 200,000 volts and the employment of

heavy filters. Fortunately, our American-made apparatus is capable of working satisfactorily at 200,000 volts and over, with means of accurately determining the voltage employed. Our technique is improved by the use of higher voltage and amperage and a consequent shortening of the time of treatment required to give the same amount of deep radiation. While there are various details that modify the actual technique of treatment, the desired amount of radiation may be applied at practically any point in the average patient through two ports of entry with a total of two to four hours' time. The total dosage is given, as a rule, in one or two treatments, though this will vary

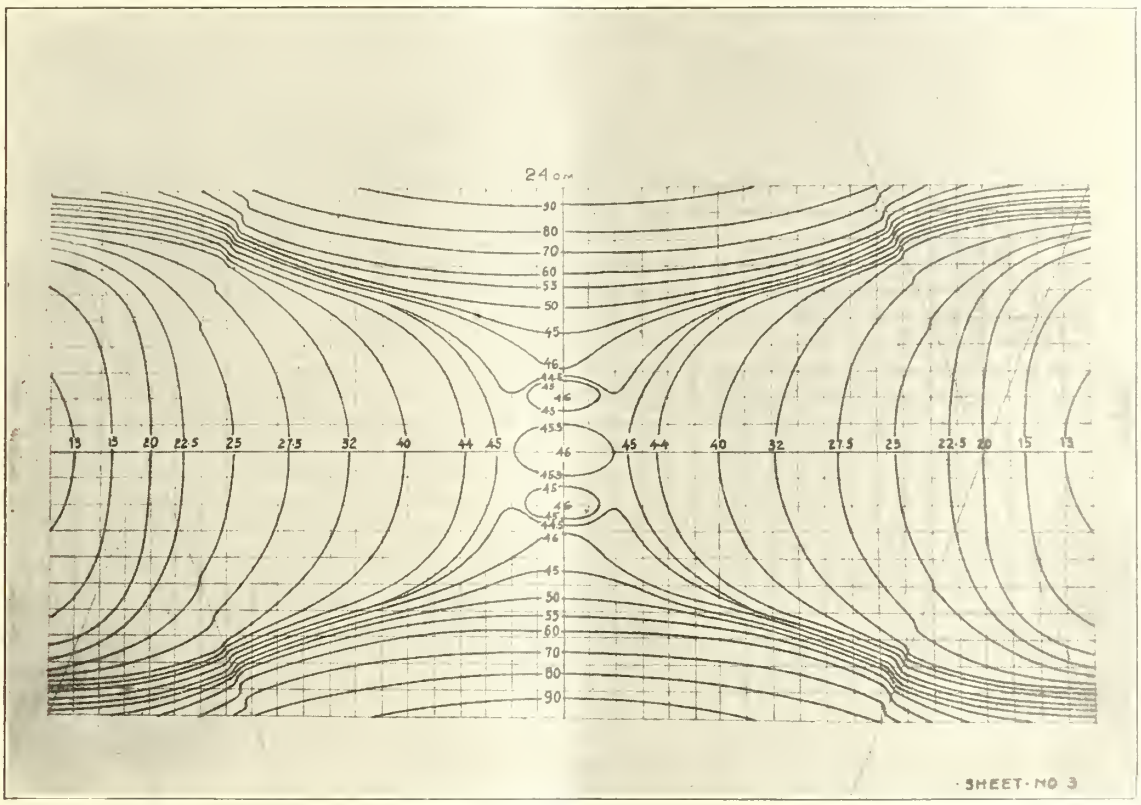

Figure 2—Chart showing distribution of intensity employing 150 k. v. plus .75 cu. plus 1 mm. al. at 50 cm. distance. 24 cm. port.

with the constitutional condition of the patient. We have observed a marked decrease in the percentage of cases showing nausea and other symptoms of constitutional disturbances since employing 200,000 volts and 5 to 8 milamperes than resulted with the previous technique.

Inasmuch as the cancer cells apparently develop a resistance to small repeated doses of X-ray or radium, it is essential that the lethal or cancer doses be administered in the shortest possible time.

Harot and Truchot report a high percentage of apparent cures of carcinoma and sarcoma treated with massive doses, and failures in patients where repeated small doses were employed. This later method is to be condemned and should be replaced by a systematic use of high doses of penetrating rays. Similar results regarding the relative effect of small repeated doses and intense radiation are reported by J. & S. Ratera, and others.

Deep X-ray therapy has been employed in European clinics largely for the treatment of deep-seated malignancies and the results reported have been consistently encouraging. Stern, in an article entitled, "Extensive X-ray Therapy as Seen Practiced in the Clinics of Europe," after reviewing somewhat in detail the technique employed in various clinics, states: "As to the choice of cases in most of the clinics I visited, I found that they had practically discontinued operating on all cases of carcinoma of the breast and the uterus. They claim that the results with irradiation alone are far superior and that they get approximately 85 per cent of cures, including all classes of cases taken at random. They were all very emphatic on the importance of never treating any type of sarcoma surgically, as the chances of metastasis are much increased by any surgical interference."

X-ray therapy with high voltage has been extended to new groups of non-malignant conditions. Hjalmas Eiken reports prompt healing in the treatment of deep purulent wounds, and favorable results in the treatment of surgical tuberculosis and carefully selected pulmonary causes are also reported by F. Jessen, Mr. M. Bechters and others.

James T. Case, whose work with high voltage equipment antedates by nearly a year that of all other workers in this country, states that high penetrating X-rays have advantage over radium for deep application, although radium will be

more in demand for use in tumors and in cavities of the body. He states that the immediate results in certain cases have been startlingly encouraging.

While our work is too recent to justify conclusions, the changes occurring and the results obtained in the treatment of a large number of benign and malignant conditions are very encouraging, and in certain cases, the immediate results have been most striking.

Relief of pain in several advanced pelvic cases has been most marked. One case of pelvic carcinoma that had been taking five grains of morphine per day, stopped voluntarily in 48 hours after the treatment was completed. Several cases of advanced inoperable carcinoma of the breast have shown marked absorption in the tumor mass and the regional lymphatics, with a consequent decrease in the swelling of the arm, and relief of pain. One case of extensive rectal carcinoma treated with combined radium and deep X-ray has shown a total absorption of the tumor mass in less than one month following treatment. Another case of large palpable tumor found inoperable at exploratory laparatomy has shown a marked reduction in size of the tumor and the patient has regained appetite, strength and weight. There are numerous other cases that have shown quite a marked immediate effect. I do not wish to be misunderstood, and fully appreciate that these cases may ultimately die a cancer death, but the palliation well justifies treatment and offers a faint possibility of cure in a small percentage at least. We feel that deep X-ray should always be used in the pre and post-operative treatment of cancer, and we are now employing deep X-ray therapy as routine in combination with radium emanation in all cases of uterine cancer and for the treatment of regional lymphatics, following the local use of radium emanation in intra-oral malignancies; also in all inoperable breast cancers and intra-abdominal malignancies, as well as in hyperthryrodism, and other appropriate conditions.

Radiotherapy, particularly by means of radium emanation, will continue to occupy a large and superior place in the treatment of a certain group of benign and malignant conditions. However, the large volume of high penetrating X-rays produced with high voltage has a broad application and greatly increases the scope of radiotherapy.

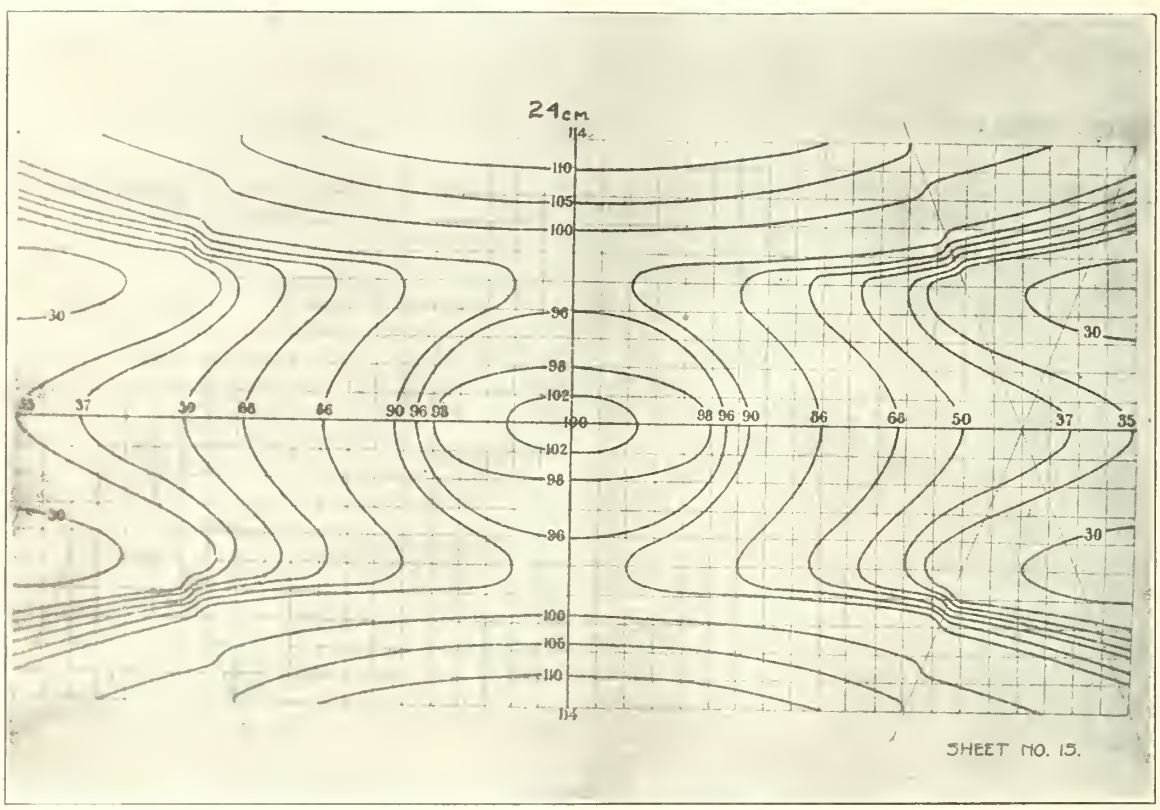

Figure 3—Chart showing distribution of Intensity employing 200 k. v. filter 1 mm. cu. plus 1 mm. al. at 50 cm. distance. 24 cm. port.

With adequate facilities for both radium emanation therapy and high voltage X-ray therapy available, it is possible to offer palliation in practically all cases of malignancy, and the percentage of ultimate cures will undoubtedly be increased. The new high voltage or deep X-ray therapy technique is upon a distinctly scientific basis, and must supersede all previous methods of X-ray therapy.

The full value of radium and X-ray therapy will not be obtained until the radiologist is consulted by the internist and the surgeon before operation, and as a consultant, given an opportunity to earlier co-operation in the selection and treatment of that large group of cases in which radiotherapy offers superior results.

GASTRO-INTESTINAL COMPLICATIONS ACCOMPANYING PULMONARY TUBERCULOSIS*

By WILLIAM C. VOORSANGER, M. D., San Francisco
(From the Oaks Sanitarium, Los Gatos, Calif.)

Good food constitutes one of the main therapeutic measures in the treatment of pulmonary tuberculosis. This does not mean, as was at one time erroneously assumed, that a tuberculous patient should be overfed and crowded beyond his capacity with large quantities of milk, eggs and cereals in addition to his regular meals. It does mean that he should have a properly regulated diet, including milk and eggs, sufficient to bring his weight to normal and restore his bodily strength and energy. However, adequate feeding of a tuberculous patient is often a practical impossibility, due to the numerous gastric and intestinal conditions, organic and particularly functional, which result as a direct concomitant of his pulmonary disease.

These problems will be analyzed as:

Functional—Loss of appetite; disgust for certain kinds of foods or for all foods; vagaries of diet; distress after eating, i. e., gas; nausea and vomiting (intestinal toxemia); coughing during eating; abdominal pain (gastralgia—diaphragmatic pleurisy); result of over-eating; diarrhoea.

Treatment—Particularly the combating of anorexia and the control of increased peristalsis by the use of intravenous injections of 5 per cent calcium chloride.

Organic—Gastric or duodenal ulcer; colitis; appendicitis; intestinal tuberculosis (differential diagnosis).

In pulmonary tuberculosis, symptoms referable to the stomach or intestine are exceedingly common. Mohler and Funk in 1000 consecutive cases found 64.6 per cent had gastric symptoms; Hutchinson in 72 per cent; Janowski 35 per cent, and Landis 55.3 per cent. These percentages are mainly for functional disturbances because actual tuberculosis of the stomach is almost unknown, occurring only twice in 2000 autopsies performed at the Brompton Hospital, London. Pulmonary tuberculosis causes a definite downward progression in gastric motility and secretory function. Hyperacidity is rare. The gastric mucosa and glands may be impaired, thus causing gastric disorders. Undoubtedly, in pulmonary tuberculosis we have delayed digestion which may produce symptoms as the primary disease progresses. Pulmonary disease often has a gastric onset, and every patient complaining of prolonged anorexia or gastric distress should have a complete physical and roentgenological examination to ascertain if pulmonary tuberculosis is present.

Tuberculosis is unquestionably a disease dependent upon lowered resistance. To arrest it, resistance must be elevated, and unless the patient will eat this is unobtainable and our best methods of treatment futile. Child nutrition is being approached from the point of view of the child being an entity because his digestion differs from the adult. We may go further and assert that adult digestions differ one from the other and that each under-nourished adult is a separate entity. In feeding a tuberculous patient, particularly one who complains of loss of appetite, his particular psychology must be considered. What were his habits before he became ill? What are his idiosyncrasies and prejudices? We base all diets on the proper relation of carbohydrates to proteins, but must not this rate differ in different individuals according to occupation and temperament? Again, how great a role the nervous system must play in its relation to digestion! Prolonged indigestion causes loss of weight and strength and diminished resistance. A proper or effective blood circulation must play an important role also in digestion and the patient's desire for food. Nutrition from the cellular point of view is intimately bound up with the idea of a normal or abnormal increase or decrease in the digestive power of the individual cell. As the end products of gastric and intestinal digestion are transmitted to the cells of the body by the plasma it is manifest that metabolism is influenced by good or defective circulation. We are wont to accept "loss of appetite" in a tuberculous patient as a natural symptom of his disease produced by a general toxemia and treat it with tonics with forced feeding, the latter often causing vomiting or nausea. Loss of appetite is often due to toxemia, but is just as often due to temperamental peculiarities, nervous symptoms or defective circulation.

A worrysome functional disturbance often more difficult to combat than anorexia, is a "disgust for certain kinds or for all foods." Patients who formerly had been hearty eaters often complain that they can no longer eat meat because the odor of it kills their appetites. Others state that although they feel like eating, they know that if they took food they would vomit, although the food did not distress them.

Such patients continue to lose weight until they are taught to overcome these peculiarities. Vagaries of diet are met with only too often in handling tuberculous patients. Common examples are those who cannot drink milk nor eat soft-boiled eggs; who will discard a whole tray because sauce was poured over the meat; who will not eat chicken; or who can only eat one kind of cereal. In fact, instances of freakishness in eating common in the healthy individual can be multiplied manyfold in the chronically sick. Nor is the condition easy to combat, since in tuberculosis our aim is hypernutrition. The very articles of food most necessary for the latter are refused in a foolish and stubborn belief that the patient cannot tolerate them. Patients who receive narcotics often take violent dislikes to the most easily digested foods.

Nausea and vomiting are the most frequent gastric or intestinal symptoms. They may be due to high temperature or to intestinal toxemia, but more often to excessive coughing, swallowing of sputum, or the clinging of tenacious sputum to the pharynx, which causes gagging and vomiting.

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May 18, 1922.

Swallowing of sputum plays an important role in the continuation and aggravation of disordered gastric function. It may best be combated by instructing the patient never to swallow his sputum. The drinking of a glass of hot water fifteen minutes before eating, particularly before breakfast, proves often most efficacious in loosening bits of tenacious sputum and counteracting the coughing and subsequent vomiting which often occurs after the first few mouthfuls of food. Pottenger explains nausea and vomiting as an expression of increased muscular tonus in the gastric walls through visceral reflexes. However we explain nausea and vomiting, it is an ever-present complication and often prevents the patient's upbuilding. Closely allied to nausea and vomiting is coughing during eating, which often induces the former. Many patients cough upon the slightest pharyngeal irritation—and the swallowing of food seems to particularly excite a pharyngeal reflex. Sometimes this coughing will not occur until the meal is completed, but whenever it occurs often expectoration and vomiting follow. If the vomiting occurs with every meal, nourishment of the patient naturally becomes a great problem. A small dose of Heroin or Codein fifteen minutes before meal time may be beneficial. Patients often develop a "habit" cough and exercise this particularly while eating. This cough can be controlled by teaching the patient to inspire when he feels the pharyngeal "tickle."

Abdominal pain is one of the most distressing symptoms seen in the course of pulmonary tuberculosis. Its causes are numerous. Certain articles of food may cause it, particularly milk. Acute epigastric pain suggestive of gastric ulcer may cease immediately after the removal of milk from the patient's dietary. A few days later the milk may be resumed without the patient feeling any distress. Eggs often have similar effect. Overeating is one of the frequent causes of epigastric pain. Excessive amounts of raw fruit also may cause violent abdominal pain. Increased peristalsis is a natural result of dietetic indiscretion—hence the necessity of making each patient a dietetic study and not feeding everyone alike or according to a fixed system. One patient may assimilate 3,500 calories daily—another may thrive and gain weight on 2,500. The greatest problem with which we have to deal is the patient himself. He believes the success of treatment depends upon cramming himself with food, particularly excessive amounts of milk and eggs, and if pain results he does not attribute it to overeating or wrong food, but to intestinal tuberculosis. It is often most difficult to convince him to the contrary.

Diaphragmatic pleurisy may cause abdominal pain, but treatment of pleurisy by aspirin and strapping will give relief. Pain in the region of the gall-bladder may suggest disease of this organ. Whereas the vast majority of all abdominal pain in the gastric or intestinal region is produced by temperamental idiosyncrasies or dietetic indiscretions, we must not forget that we may have organic causes such as gastric ulcer, appendicitis or intestinal tuberculosis. Appendicitis of tuberculous origin or otherwise is a condition which must always be kept in mind in acute abdominal pain.

Diarrhea, so frequently coincident with pain in the abdomen, is sometimes of organic origin, but more often it is due to dietary indiscretion. No combination of symptoms will so upset the patient's equilibrium and cause discouragement as diarrhea and pain. He has, of course, heard or read that these are cardinal symptoms of intestinal tuberculosis, and it often may take all one's tact to persuade him otherwise. To accomplish prompt relief of the condition is, of course, the best argument. When milk is the cause it should be stopped for one or more days. If it is due to intestinal toxemia, irritation of the gastric or intestinal mucosa or even a slight tuberculous ulceration, a 5 per cent solution of calcium chloride intravenously is useful. An initial dose of two cc. seems best. After four to five days, if no result is apparent, a dose of five cc. may be given and repeated weekly if required. Sometimes the immediate effect of the treatment is brilliant, the pain and diarrhea ceasing in twenty-four hours. This applies principally to cases of functional disturbances with little or no organic involvement. In one patient with marked intestinal tuberculosis accompanied by severe pain and diarrhea the symptoms disappeared within twenty-four hours after the injection. He eventually died, but for months previously he received considerable comfort from injections from one to three weeks apart. Calcium chloride very probably operates through inhibition of peristalsis, and of course its action is purely palliative. The author of the treatment maintains that relief is always obtained in the absence of excessive intestinal ulceration. Its value is great principally in cases of stubborn pain and diarrhea when definite cessation of these symptoms will convince the patient that his condition is not hopeless.

There is no more important problem than the determination of the status of a tuberculous patient with abdominal symptoms. Edward Archibald makes a plea for early recognition and surgical treatment of true tuberculous involvement of the intestine. He states "when a patient complains of pain in the mid or lower abdomen at irregular intervals during the day, but chiefly in the late forenoon or afternoon, these pains being crampy of stabbing, aggravated by food and relieved by fasting, felt only during a part of the day, then one must be very suspicious of tuberculosis. When he has loss of appetite—real distaste for food; when he has nausea at times; when he gives up one article of food after another; when he develops a slight fever which is not attributed to his lung condition, and if this persists over three or four weeks—then one may be almost sure of the diagnosis." Archibald is correct in urging an early diagnosis of true intestinal tuberculosis, because surgery offers a result in a percentage of these cases and temporary relief in the majority. I have seen the symptom complex detailed above as being pathognomic of intestinal tuberculosis disappear permanently under rest and

proper diet. In this event it was no doubt caused by functional disturbances or faulty diet.

In determining our diagnosis we should never forget that the tuberculous patient may develop the same abdominal conditions as the non-tuberculous patient, i. e., gastric or duodenal ulcer, gall-bladder disease, colitis or acute appendicitis. The differential diagnosis of these conditions from tuberculosis is not always easy—particularly as one hesitates to submit a patient with pulmonary involvement to an operation. We are often confronted with the problem of whether we are dealing with a diaphragmatic pleurisy or gall-bladder disease; whether an epigastric pain persisting is due to gas or an ulcer; whether a colitis is toxic, infectious or tuberculous; whether pain in the right lower abdominal quadrant is due to appendicitis or not. In the last named, blood examination will often clear the diagnosis except in the sub-acute forms. It is necessary to keep all these conditions in mind, when a patient with pulmonary tuberculosis develops abdominal symptoms, particularly since the latter may be independent of his tuberculous condition, which even more complicates the picture.

Fluoroscopy may be of some assistance in making a diagnosis in intestinal tuberculosis. Pirie, who did the roentgenological work for Archibald, states: "In a tuberculous subject with symptoms suggesting tuberculous caecum, if the caecum did not fill from four to twelve hours after the barium meal, when examined at intervals of about half an hour, then the want of filling confirms the diagnosis." In the few cases which I have fluoroscoped I have never been able to obtain positive evidence.

The decision as to whether the abdominal symptom complex is functional, due to diet, or whether it is organic, is important, because if the last named surgery becomes necessary. This paper cannot go into the surgery of intestinal tuberculosis. The results are occasionally permanent in the early mild ulcerative type of colitis, but in most cases they are palliative. It is my belief that the patient with pulmonary involvement should be given every possible chance with conservative methods before submitting him to a radical surgical procedure. Above all things, his pulmonary lesions must not be too far advanced if he is to submit to an operation for intestinal tuberculosis.

CONCLUSIONS

This brief paper does not attempt to present any new complications of tuberculosis. It is an analysis of certain practical problems which are worrysome and at times difficult of solution in the feeding of tubercluous patients.

The majority of gastric and intestinal symptoms in patients suffering from pulmonary tuberculosis are most probably due to toxemia, functional disturbances, dietary indiscretions or temperamental peculiarities.

Gastric tuberculosis per se is very rare, and intestinal tuberculosis, except in advanced cases, should only be diagnosed after most careful investigation and giving the patient the benefit of the doubt. Where definite intestinal tuberculosis has been absolutely verified, surgery may prove palliative.

It is most important to study the psychology of every patient—to recognize that adult digestions differ, and not attempt to feed patients by any fixed rule, but to carefully differentiate and individualize.

In abdominal pain and diarrhea calcium chloride 5 per cent injected intravenously is of considerable benefit.

The Problem of the Medical Parasite—The charge that the practice of medicine is not an exact science has been permitted to go unchallenged for so long that the statement has come to be generally accepted as true. Medicine is entitled to be called a science, and much of it exact science. The facts of anatomy are fixed and constant. Pathology is almost as constant as anatomy. Chemistry and physics are everywhere regarded as sciences. Bacteriology is as exact as botany, and botany is certainly entitled to rank with the other subdivisions of the great comprehensive science of biology. There is nothing in human experience that is entitled without reserve to be called exact—not even mathematics.

Most of the States have fairly good medical laws, but through most of them runs a common weakness— a section containing a list of "exemptions."

Under this heading will be found such medical parasites as have been legalized by indirect means. The problem of the medical parasite is peculiar to our own country. No other political subdivision of the civilized world gives legal sanction to the exploitation of its sick. One searches in vain through the medical laws of the nations of the earth sufficiently advanced to have medical laws, for any parallel to the desecration of medical law that prevails in our own United States of America. The composite list of the parasites found under the "exemptions" of the various States is a long one—and it is growing. The Legislatures of the different States are struggling valiantly to overtake the demand. The task seems well nigh hopeless, still there is, as yet, no sign of giving up the chase.

Laws that grant "limited licenses" to persons of limited qualifications are not laws in the interest of public safety. The "limited" applies only to the qualifications of the holder of the license. There is no limit to the character of the ailments that the "limited" license entitles its holder to attempt to treat. If the "limited license" were limited in the sense that diseases to which the specified limited treatment was unsuited could not be dealt with, some of the danger might be eliminated. As it is, some of the most pernicious of these "limited" practitioners treat in their own limited way diseases which are necessarily fatal unless treated by methods which by law are denied to the holder of said limited license. The law plainly says that certain methods of treatment are forbidden, but is silent on the vital point of what diseases must not be treated by the limited methods permitted the holder of the limited license. Withholding the proper treatment may cause the death of the patient just as surely as applying the wrong treatment. The limited practitioner not infrequently makes away with his patient by this indirect method. This way of killing people is legalized in many of the States—and Illinois is one of them.—(Illinois Medical Journal, June, 1922.)

AMOEBIC ABSCESS OF THE LIVER*

By HORACE J. BROWN, M. D., Goldfield, Nev.

For one who has always practiced in the temperate zone to write about amoebic abscess of the liver would seem to be presumptious, to say the least, since probably ninety per cent of such cases are seen in the tropics, and those that we see in this latitude usually give a history of having resided in the tropics. I must give as my excuse for writing on this subject my belief that I have found an important symptom that has heretofore been overlooked. While it may be a case of "the inexperienced finding all of the wonderful cases," I can at least say that the records seem to support me in my belief. In order to be as brief as possible, I will report a case that came under my care recently.

CASE REPORT

Mr. P. C. had been given a diagnosis of cancer of the liver and stomach, with a hopeless prognosis. One month later he entered the hospital, begging that something be done for him to relieve his suffering. The patient was a miner, 57 years old, and a native of Genoa, Italy. He came to the United States in 1893 and lived for about fourteen years in Seattle and Alaska. For the last fifteen years he has lived in Nevada, except for six weeks spent in Los Angeles for medical treatment in 1916. The first illness he remembers was in 1906, when he began having dysentery and hemorrhoids. He failed to get relief until 1918, when an examination of his stools showed entamoeba histolitica, and he was quickly cured with ipecac (this information was obtained from the physician that treated him). His family history was negative. His chief complaint was nausea, vomiting, pain in epigastrium, and loss of weight. A carefully kept chart from June 8 until July 5 (1921) showed a temperature never above 99 and pulse never over 84, with no chills or sweats. Patient stated that he had never had either chills or sweats. His present trouble began to manifest itself in the fall of 1919, when he began having epigastric distress. At the time of examination his temperature was 98.6, pulse 84, respiration 20, the heart action being irregular. Weight 130 pounds, normal weight 165 pounds. He had an appearance of general malaise, with an expression of depression. In general appearance he was tall, thin, stooped, with lustreless eyes with slight injection of the conjunctivae. The teeth showed extensive pyorrhoea. The tongue was moist and coated moderately. The lungs were normal, as was the heart, except for the irregular action noted above. Palpation showed a large tumor in the upper abdomen which filled the epigastric and right hypochondriac regions. Urinalysis was entirely negative, except for the presence of a small amount of indican. The examination of the feces did not show either blood or amoeba. The blood count showed 8500 white cells with 60 per cent polymorphonuclears, red cells 4,000,000, and a negative Wassermann. The test meal showed the entire absence of hydrochloric acid in the stomach, and repeated examinations failed to show any blood. The X-ray pictures showed a large subdiaphramatic tumor pushing a normal stomach downward and to the left. On palpation the tumor was found to be smooth with no nodules palpable anywhere on its surface. The patient's skin was sallow and of a muddy color. A diagnosis of amoebic abscess of the liver was made and on July 5th an incision was made three inches to the right of the median line, in the upper abdomen, and the abscess drained of a little over two pints of pus, in which no amoeba were found. The abscess was in the right lobe of the liver, and the pus was mostly thin and white. The gall bladder was distended and slightly inflamed, and there was considerable thickening of the cystic duct, but the gall bladder emptied easily under pressure. The other abdominal organs were normal. The abscess cavity was irrigated daily with an iodine solution and the patient given, by hypodermic, one c. c of emetine solution daily for twelve days. Recovery was uneventful and he left the hospital on August 26th with only a small discharging sinus which healed in three or four weeks.

The points of particular interest in this case are the absence of all signs of pus, the fact that he contracted the disease in this latitude, and the absence of hydrochloric acid in the stomach. A careful search of the literature fails to show any detailed report of the analysis of the stomach contents and, in fact, only one author mentions it at all. W. J. Mallory (Journal A. M. A., Vol. 75, Page 1774, 1920) reports the examination of the stomach contents, but with a negative result. He also states that "amoebic dysentery, and therefore amoebic abscess of the liver, may occur in persons who have never been in tropical or subtropical countries." I have had one other case of dysentery due to the entamoeba histolitica in Nevada, but that case has not as yet developed abscess, and I have been unable to learn of any other cases. I have reported this case in order to bring out the following facts: (1) Owing to the rarity of amoebic abscess of the liver in this latitude, there is the danger of overlooking the condition unless every facility is used to aid in the diagnosis. (2) The peculiar condition in this case wherein all of the signs and symptoms of pus were lacking, i e., the normal blood count and the absence of chills, fever and sweating. (3) The possible value as a sign of achlorhydria, as found in this case.

Medical Licensure in Illinois—Following the licensure scandal in Illinois a year ago, at least two investigating bodies have recommended to Governor Small that Director W. H. H. Miller be removed or suspended from office. One was the special committee apointed by the governor himself to make an investigation. Nevertheless, the governor has refused to heed the recommnedations. Although Director Miller was charged with trafficking in examination papers and physicians' and pharmacists' licenses, his attorneys are attempting to prove, not that Miller et al. were not guilty of the acts indicated, but that they were violating no law and, therefore, that the acts did not constitute a crime! How will the licensing boards of other states regard these actions? Will they be willing to continue reciprocal relations with Illinois when the licenses granted are under such suspicion? Can any excuse be found for such bartering in certificates and licenses as has apparently been done? How about the interests of the public which the state employe is supposed to conserve?—Journal A. M. A., July 22, 1922.

As Lightning Precedes Thunder—When psychoanalysis was more a study and less a fad, Mrs. Elsie Lincoln Benedict, lecturer, traveled singly. But not so now. She marched into the Whitcomb Hotel yesterday with a retinue of some twenty people—lecturers, assistant lecturers, brainologists, personalitists, psychologists and mental analysts. Mrs. Benedict is the daughter of a former mayor of Pomona. She is registered from Detroit.—San Francisco Examiner, June 24, 1922.

THE DIAGNOSIS AND TREATMENT OF GALL BLADDER DISEASE.*

By WALTER C. ALVAREZ, M. D.

PART II.

The first installment of my article, published last month, dealt largely with what not to do in the diagnosis and treatment of gall bladder disease; this second part will deal briefly with the things which I think should be done.

THE FREQUENCY OF GALL BLADDER DISEASE

First, I should state that statistics from many sources show that from five to twelve per cent of all women coming to autopsy have gall stones. If we exclude women under fifty, the percentage is still higher. This alone would be bad enough, but we know that there must be a still larger group of men and women in the community suffering from the pre-calculous stages of cholecystitis. There would seem, then, to be no escape from the conclusion that even the careful clinician is not making the diagnosis of gall bladder disease often enough. The writer gets the idea sometimes that he is becoming mentally warped on the subject because he suspects cholecystitis in every old lady who comes in with flatulence and abdominal pain; and then along come a few autopsies or operations on his patients and he discovers a number of gall stones, the presence of which he had not even suspected.

Now, how are we going to recognize a larger percentage of these cases?

A GOOD HISTORY

First, and above everything, comes a good history. A case will often seem puzzling until skillful questioning brings out the story of one or more attacks of supposed ptomaine poisoning which really had all the earmarks of gall stone colic. The physician must remember that recurrent attacks of severe pain which perhaps waken the patient out of a sound sleep and which leave her upper abdomen sore for days afterwards are due to organic disease; they cannot be ascribed to a neurosis or to slight indiscretions in diet. In the most typical cases the pain begins in the liver region and runs up into the right shoulder blade. Often there is a constant ache on the right side. The soreness is aggravated by riding over a rough road or by reaching up on a shelf. Women perhaps will be unable to bear the pressure of their corsets in the liver region. In milder cases and in the intervals between attacks, the patients complain mainly of belching and bloating. They often feel "bilious" and get a little sallow. Only rarely are they jaundiced. Nausea, regurgitation of food and heartburn are common. Vomiting often comes during the attacks of pain.

Most characteristic and helpful is the patient's statement that although she has a fine appetite she is afraid to eat. She dreads the return of pain. Yet she will admit that what she eats seems to have little or nothing to do with the coming of an attack. She may get a bad one after a week of fasting, and later she may digest a Thanksgiving dinner without discomfort.

Several suggestive points may be mentioned. A history of a useless appendectomy shows that the symptoms were so bad that the patient was willing to do anything to get well. A history of typhoid fever, chronic sinusitis, empyema, or any other severe and prolonged infectious process is helpful because such things often leave the gall bladder damaged irreparably.

The presence of arthritis, myocarditis and certain forms of headache and dizziness is suggestive because these troubles sometimes clear up after cholecystectomy.

THE PHYSICAL EXAMINATION

This generally shows a woman between forty and sixty-five although, as our experience grows, we are going to recognize cholecystitis more and more in the twenties and thirties, and even in childhood when the trouble often begins. In subacute cases the patient gives a jump when a deep breath brings the tender liver edge down against the palpating hand (positive Murphy's maneuver). The presence of fibroids in the uterus, or other pelvic abnormalities, greatly increases the probability of finding gall bladder disease.

ROENTGEN-RAY EXAMINATION

This can help greatly in several ways. First, it may exclude the presence of other organic lesions such as ulcers and carcinomas.. Second it may show the shadow of stones or of a thickened gall bladder on the plate. Unfortunately most of the diseased gall bladders are free from stones and so thin-walled that they will not show on the plate. Furthermore, many stones are too soft to give a shadow. Third, the screen examination often shows many suggestive things. Cardiospasm is often seen, and I am coming to think more and more of it as an indicator of gall bladder disease. The stomach is often hypertonic and overly active; and not infrequently the pyloric antrum is contracted and sharply conical in shape. There may be some gastric stasis, and it may also be apparent to an experienced observer that the gastric mucosa is dry (achyliac). The duodenal cap is sometimes deformed by adhesions or pressure, and it may also show defects in emptying. The colonic haustration is often exaggerated. The liver is not infrequently enlarged from the cirrhosis attendant upon prolonged infection of the bile ducts.

LABORATORY TESTS

Gastric analysis often shows an achlorhydria. In the first part of my paper I have explained why I think the Meltzer-Lyon test should not be used diagnostically.

TREATMENT

Like appendicitis, gall bladder disease may go on and kill the patient or it may clear up even without treatment. Once cleared up, it may leave the victim alone or it may come back at intervals until finally something has to be done. We know now that it is best and safest to take diseased appendices out. Unfortunately, we do not know

* Read before the Section on General Medicine of the Medical Society of California May 16, 1922 at Yosemite National Park.

yet what to do with the early cases of gall bladder disease. If we could only look into the future for the different individuals it would be easy. When I see women about sixty-five, emaciated, worn with suffering, anxious for an operation which they cannot well stand, I tell myself that it is my moral duty to urge the younger ones to go to the surgeon. When, however, I see a series of women about forty who have gone ten or fifteen years without attacks or much distress, I waver, and am inclined, as is the patient, to let well enough alone.

Unfortunately, it seems impossible to say when these people are really "cured" and free from the menace of their diseased bile tracts. Thus, one would think, after several attacks of gall stone colic that an interval of twenty years without troublesome symptoms would indicate a cure, but I have seen a woman in whom such a period of relief was really only an interlude. When she was sixty-one her troubles returned; a plate showed that a stone still remained, and an operation showed that a carcinoma had developed somewhere in the biliary tract.

It is hard to say whether medical treatment does much good because remissions occur so frequently and come so suddenly. Ordinarily it is well to advise a smooth, cellulose-poor diet; that is, without salads, coarse vegetables, or fruits. Some people are helped by the taking of Carlsbad salts in hot water before breakfast. Belching and heartburn are often helped by the giving of sodium bicarbonate and magnesia. Hoffman's anodyne often brings relief during attacks at night. During paroxysms of pain, paregoric, morphine and papaverin have to be used. The physician should remind the patients who are losing weight that they will probably have trouble whether they eat or not, so that they had better eat and keep their strength.

DIFFERENT TYPES

For therapeutic purposes the cases may at present be divided into six or seven groups. Medical treatment should be reserved for:

First, those who are in the early stages of the disease, with mild symptoms and long intervals of relief, whose bodies are still young and strong, and who may perhaps yet hope permanently to overcome the infection.

Second, those whose symptoms and findings strongly suggest the presence of cholecystitis but who are suffering so much from nervousness, menopausal storms, hypertension, or myocarditis that it is a question whether they would be any better off even if a markedly diseased gall bladder could be removed safely. These people must be studied carefully before any decision is made in regard to operation.

Third, those who need and want an operation but who, on account of complications, cannot undergo it with any prospect of success.

Fourth, those who have had a cholecystectomy but who still suffer. Many of these people might have gotten a perfect result if they had been put on a smooth diet after operation.

In the absence of definite contra-indications operation should be advised for:

First, those who have reached that stage of the disease in which the attacks are getting steadily worse and more frequent.

Second, those whose indigestion is severe enough to interfere with ability to work and to enjoy life. They should be the more willing to accept operation if they have an arthritis, headaches, dizziness or myocarditis, which may perhaps be cured by the removal of the infected gall bladder.

Third, those who have had their gall bladders drained and who had gotten relief, but who now return with pain and perhaps with new stones.

Finally, and this is a most important point: The surgeon must be willing to admit that at the time of operation he cannot tell a diseased from a normal gall bladder. Men of experience know that not infrequently gall bladders which, according to the history, must have been discharging stones off and on for twenty years, are found at operation to be still soft and apparently normal. If they were not full of stones the surgeon would generally pass them by as inocuous. This does not mean that I am arguing for the reckless removal of gall bladders. Far be it from me; but as Judd says, there is no doubt that in many cases if the patient is to be helped, his gall bladder must be removed on the strength of a careful history taken by an experienced man. This removal can be done with more confidence if there are no other signs of disease in the abdomen to explain the severe symptoms, and if there are adhesions about the gall bladder, an enlarged gland near the cystic duct, an enlarged liver and signs of perihepatitis and pancreatitis. I am convinced that the poor results obtained in many of the cases of operative interference for duodenal ulcer can be ascribed to the leaving behind of gall bladders which had become badly involved in the inflammatory process about the bowel.

Training in Sociology and Public Health an Essential in Medical Education—S. W. Welch, Montgomery, Ala., suggests five essentials which should be made a part of a student's medical education: (1) He needs to have a sympathetic understanding of the fundamental human problems in relation to the many complexities of modern life, and must become familiar with the trend of the best thinking along social lines. (2) He needs to know the place and function of sanitation in relation to the public welfare, the how and when and why of environmental influence on health. (3) He needs to be well grounded in the control of the communicable diseases and in bacteriology. (4) It is imperative that he should have a knowledge of hygiene, especially in its relation to the social and medical sciences which attempt to improve the race by approximating a solution of the basic problems of human existence; that is, the problems associated with the necessity for food, shelter, defense and propagation. (5) He needs to have a knowledge of psychology in its relation to conduct, with regard both to individuals and to groups, in order that he may truly educate both individuals and groups in right habits of action, by supplying motives which appeal to them.—Journal A. M. A., July 29, 1922.

CHRONIC SUPPURATIVE PAROTITIS WITH ACUTE EXACERBATIONS*

By HENRY J. PROFANT, M. D., Santa Barbara
(From the Santa Barbara Clinic)

The parotid gland is subject to two separate inflammatory reactions: the epidemic parotitis or mumps, and the secondary or sometimes called symptomatic parotitis. Mumps appear as a peculiar, primary, infectious disease, usually epidemic, and are rather common. The contagious character, regular incubation period and typical course suggest that the disease is due to a specific organism, but this has not been definitely determined. Suppuration scarcely ever occurs in genuine mumps. The secondary form, acute suppurative parotitis, is a rare condition, as one finds upon referring to the literature on the subject. The case I wish to report is of special interest because of the repeated acute attacks imposed on a chronic suppurative parotitis.

HISTORY

The history is as follows: Mrs. W., age 61, American, was always delicate as a child, and had measles, malaria, chicken-pox, frequent peritonsillar abscesses and typhoid fever. At the age of twelve she had mumps of the right parotid gland with an uneventful recovery. During adolescence and early womanhood she enjoyed fairly good health, but was never robust. Since then she was operated for a strangulated ovarian cyst and had the left breast removed for a suspected carcinoma. At the age of forty the right parotid gland became acutely inflamed. No operation or serious illness preceded this attack, and for a time it was considered as another attack of mumps. However, after the acute symptoms subsided the gland failed to return to normal. Each day it was distended with a thick yellowish-white material, which would not evacuate spontaneously but had to be expressed from the gland through the duct. This condition has remained and has behaved analogous to a chronic suppurative dacryocystitis, with recurring acute attacks. In the past twenty years she has had fifteen acute attacks varying in severity and duration. Unfortunately this affection is only one of many other disorders, and her chief complaint is a severe bronchial asthma which began fourteen years ago. Since the onset she has sought relief in many parts of the country, but it is one of those severe forms of asthma in which practically everything has been tried with disappointing results. Lack of time prevents me from considering the asthmatic condition except from the standpoint of the possible relationship to the parotid gland and vice versa. The chronic suppurative condition of the gland is determined by an examination of the material which is expressed daily. The smears show numerous pus cells, and cultures usually show staphylococci, although at intervals streptococci viridans have been isolated. I have personally observed the last two acute attacks.

The first of these occurred in May, 1921, and according to the reports of the patient's daughter, who is her constant companion, the attack followed the usual course of the preceding severe ones. I was called because the patient could not empty the gland. There was a swelling the size of a walnut, but no external signs of inflammation; no redness or tenderness. As had been done in the previous attacks, I probed the duct, found it patent, and injected normal salt solution. Heat was applied externally. These measures were continued daily, but no drainage was obtained. The gland increased in size and by the third day became tense, tender and painful. The temperature rose to 102 and the white count to 15,000. Large doses of bromides and codeine became necessary. An X-ray was taken, but no calculi were seen. The fifth day drainage began spontaneously and foul-smelling pus exuded from the duct in which streptococci viridans were isolated. By the twelfth day the gland resumed its chronic condition.

The past two years the patient has been confined to bed because of the severe asthma, an alarming attack occurring every two or three months. The first week in April of this year she had a violent gastric upset with nausea and vomiting, and it was necessary to give merely glucose per rectum for two days. Milk was resumed when the attack subsided.

A few days later, April 15, the gland again failed to empty. The course differed this time in that the gland failed to drain the fifth day. Expression of the gland and duct, probing and injection of one to two ccs. of normal salt solution were again attempted. On the sixth day the skin over the gland became red and in spots almost purplish, and an edema of the cheeks and eyes occurred. The temperature rose to 101 and remained about that until the seventh day, when there was a decided chill, followed by a temperature of 104 and a white count of 20,000. Any operative interference had been delayed because of the fear of a permanent fistula, and the fact that in the fifteen other attacks the pus eventually drained through the duct, but this time the general condition demanded interference. An ounce of foul yellowish pus was aspirated from a point of fluctuation 2 cm. from the angle of the jaw, and a drain introduced. A blood culture taken at this time was negative. Dr. Andrews, who had seen the patient during an acute attack five years ago, suggested intramuscular injections of 5 cc. sterile milk every third day for its alexin action. Good drainage was maintained, the inflammation gradually subsided, and in two weeks the wound closed spontaneously. The gland has again resumed its chronic condition. The observation of the two acute attacks and a study of the cases reported in the literature lead to several conclusions. A brief review of the essential points of the anatomy and physiology of the gland is necessary.

ANATOMY AND PHYSIOLOGY

You recall that a simple gland is one which remains undivided; and that a compound gland, on the other hand, is one that breaks up into two or more branches, and may be tubular, alveolar or of a mixed tubular and alveolar form. The parotid gland is a typical compound acinous gland; that is, it is composed of a main duct which branches and re-branches freely. The terminal divisions of the ducts end finally in specialized secreting parts known as the acini. The gross structure of the gland consists of a number of masses, often as large as peas, which are surrounded and held together by connective tissue. These are known as lobes, which in turn are made up of a number of smaller masses known as the lobules. The parotid fascia, which is a continuation of the deep cervical fascia, forms a firm capsule for the gland. The main duct (Stenson's) opens into the vestibule of the mouth by a very small orifice opposite the crown of the second upper molar tooth. Its turn around the anterior border of the masseter muscle must be borne in mind in passing the probe into the duct from the mouth. The salivary glands secrete under nerve stimulation. The parotid nerves are derived from

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

the auriculo-temporal and from the sympathetic. An inhibition of secretion is therefore an inhibition primarily through the nervous system.

ETIOLOGY

Acute suppurative parotitis, as stated before, is a secondary condition and may occur in the course of an infectious disease, but most of the cases reported are those occurring as a post-operative complication. There is a diversity of opinion as to the etiology. Paget in 1886 proposed the term sympathetic parotitis. He observed that the cases usually followed operations on the ovaries or other genital organs.

Hauan and Pilliet first suggested in 1889 that parotitis could occur as a secondary infection of Stenson's duct by mouth organisms, called an ascending infection. They demonstrated that the inflammatory processes begin in the center of each lobule and spread later to its periphery. A number of men accept this theory. Frank reports cases following appendicitis, one fatal, and concluded that its origin is due to an ascending infection of Stenson's duct. Collins reports eight cases, post-operative, with four fatalities, and concludes that its development is favored by a dry condition of the mouth and a lack of fluids in the body, and that it is an ascending infection. Clause and Duplay concluded from clinical observations and experiments on animals that infection of the parotid occurs in abnormally predisposing conditions; that micro-organisms introduced must be excessive in number and very virulent; that the general vitality of the animal must be lowered and that the normal secretion of the parotid altered in quantity and in quality.

Fisher reports twenty cases, and after a careful study of the subject concludes that septic parotitis is hematogenous in origin; that secretion of the gland is under the influence of nerve stimuli; and that the incidence of post-operative parotid involvement is neurologically dependent upon surgical shock or inhibition of the secretory and trophic fibers from higher psychic centers. Deaver classifies post-operative parotitis into three groups: metastatic, occurring only in pyaemic condition; escending parotitis due to ascending infection via the duct; and traumatic, the result of direct pressure on the parotid gland. Blair believes neither theory, hematogenous or ascending, is above dispute. The behavior of one of his cases has suggested to him the probability of stone irritation or obstruction.

There are two essential factors in the production of an acute attack of parotitis. There is a predisposing cause and an existing cause. The latter, of course, is the infection, which may be hematogenous, ascending through the duct or in the gland as a chronic infection. The predisposing cause is apparently more important, and this is the inactivity of the gland. The inactivity due either to inhibition of secretion by shock or lack of stimulation from oral starvation. This inactivity is illustrated in the report of Rolleston and Oliver following the medical treatment of 1000 cases of gastric ulcer; they found that secondary parotitis occurred ten and a half times more frequently in cases treated by oral starvation than in those allowed food by mouth. Preceding the present acute attack, as mentioned above, the patient has a gastric upset in which it was necessary to institute oral starvation for two days. The inactivity of the gland apparently produces a stasis which increases the susceptibility of the gland.

The treatment of this affection may be considered under prophylactic and active. The former consists in maintaining an active secretion of the gland. Fenwick, in an article entitled "The prevention of Parotitis During Rectal Feeding," states that he had the patients suck an India rubber teat about two inches long, which produced the desired effect. Collins states that a good way to excite the secretions of the mouth and keep the current of saliva is to allow the patient to suck on a stick of lemon candy after operation. In the active treatment of an acute attack one must consider the general condition of the patient and the severity of the local condition. Morestin, in 1907, advocated expression of the duct; he reported a post-operative case which became fluctuant and was relieved by this means. Picque pointed out that when suppuration occurs it results rapidly and habitually within thirty-six hours of the infection. He states that nothing from a clinical standpoint allows any differentiation, at least in the beginning, between the gangrenous and other types. The gangrenous types always appeared fatal to Picque. He never allows a parotitis to evolve spontaneously. Wagner, in 1904, stated that post-operative parotitis ends in death in 30 per cent of the cases. Lequen in 1907 emphasized the fact that when the treatment is by incision the surgeon must not count upon finding fluctuation. Owing to the very close texture of the parotid, the pus infiltration into the glandular tissues, creates multiple pockets, and, exceptionally, collects. He concludes that a single incision sometimes is sufficient, but often multiple incisions are necessary. Gary, in 1911, stated that suppuration is not always easy to recognize; and he has noted a rupture through the skin, auditory canal, sheath of sterno-mastoid, mediastinum, and a retropharyngeal abscess formed. In their reports Frank, Blair, Collins, Deaver and Fisher advise early incision and drainage. You recall that the essential pathology of an acute inflammation is a swelling of the epithelial cells of the acini. This hypertrophy causes a blocking of the many collecting tubules, a retention of saliva results, and with the continued inflammatory reaction the gland becomes swollen. The parotid fascia forms a firm capsule about the gland, and pain results from the marked tension. It is essentially a pressure pain. Suppuration increases the severity of the condition, but because of the firmness of the parotid sheath its degree cannot be determined. The treatment, therefore, must aim to reduce the inflammation, relieve the pain and promote drainage. The probing of the duct is a good means of determining the presence of a stone, but when it is found patent no further use is necessary. I have been convinced that the attempted irrigations of the gland through the duct with the hope of "soften-

ing the material" is unsatisfactory. Immediately following the injection the pressure pain increases in severity. As long as the epithelial cells are swollen and compress the collecting tubules leading to the duct, the many branches cannot be reached by probing or irrigation. What benefit may be derived by this means is greatly offset by the increased pain, edema of the surrounding structures, and the fact that drainage is not established or the course of the acute attack shortened. Heat locally and at times alternating with cold compresses are the best means of reducing the inflammation and pain.

Reports show that the condition must be considered seriously; the mortality has been given as high as 30 per cent. The consensus of opinion is that if the inflammation is increasing, or is no better by the fourth day, the gland should be incised and drained.

CONCLUSIONS

That chronic suppurative parotitis with acute exacerbations is a rare condition.

That an acute attack is predisposed by inactivity of the gland.

That susceptibility of the gland is favored by stasis.

That the exciting cause is an infection present in the chronic condition of the gland.

That the prophylactic treatment is the maintenance of an active secretion.

That the active treatment is local application of heat alternating with cold.

That the condition must be regarded with concern and drainage established by free incision whenever the general symptoms warrant.

Syphilis of the Lung—The results of a study of all the patients admitted to the Cincinnati Tuberculosis Sanatorium (a municipal institution) for two years are given by Alfred Friedlander and R. J. Erickson, Cincinnati (Journal A. M. A., July 22, 1922). About 65 per cent of the cases belong to the far-advanced group. During 1920-1921, 791 adult patients were admitted to the sanatorium. Thirteen per cent of all patients living had positive blood Wassermann tests; 17 per cent of all patients dying had had positive Wassermann tests. In this series of 791 cases, the diagnosis of pulmonary syphilis was made in four (0.5 per cent). All four cases occurred in white patients, three men and one woman. The diagnosis of pulmonary syphilis was not made in any of the 182 colored patients. The woman with pulmonary syphilis died; she had a combination of pulmonary tuberculosis and syphilis. The three men recovered, two under intensive antisyphilitic treatment, the third without such treatment. In addition to these four cases, two other cases of pulmonary syphilis from the wards of the Cincinnati General Hospital are reported.

Utah State Medical Association—The twenty-eighth annual session of the Utah Medical Association will be held in Salt Lake City August 31, September 1 and 2. Among the interested features of this meeting will be the course in clinical diagnosis to be conducted by Harlow Brooks of New York City. The clinics will be held daily in the County Hospital in Salt Lake City. The program of the State meeting contains many interesting papers by the physicians and members of the Utah State Society and distinguished guests. A. C. Behle is president of the society and William L. Rich secretary.

WHY MEDICAL SOCIAL SERVICE DESERVES A PLACE IN HOSPITAL ORGANIZATION, AND THE DUTIES OF MEDICAL SOCIAL WORKERS TOWARD HOSPITAL ADMINISTRATION

By FRANKLIN R. NUZUM, M. D., Santa Barbara, Cal.

In approaching the question as to why medical social service should occupy a place in hospital organization, let us review briefly the four duties of a hospital. They are:

1. The care of the sick.
2. The advance of medical science.
3. Making the hospital a center for activities concerning preventive medicine and community health.
4. The training of hospital personnel.

The care of the sick has been considered a duty belonging solely to the hospital. The medical responsibility rests with the physician. But the hospital and the physician have both found that medical social service is of great aid in obtaining the co-operation of the patient, in carrying out medical orders more effectively, and as a result of these and other helps actually hastening convalescence. In short, this means that the medical social worker is materially aiding in the care of the sick. In 1898 Sir Wm. Osler said as he looked over the patients collected in a medical dispensary: "If three out of ten of these get what they really need we are doing well. We are not equipped to treat the other seven." This statement still holds true. Why? Because the other seven need more than medicine and surgery. They need personal contact and help of various kinds, such as medical social workers are trained to give. This help is primarily therapeutic and of a kind hitherto much neglected. And what does this mean to the patient? Let an illustration answer. A patient is admitted to the hospital with a decompensated heart. He has but a limited fund of money for the care of his family while he is out of work. He does not do well in the hospital, because he soon finds that he will require a longer period of rest than the fund for the maintenance of his family will permit. He worries, he becomes restive, and in spite of the fact that the hospital and physicians are giving good service and treatment, the patient is not doing well. How many times has such a patient left the hospital and returned to work? But he is soon back. The hospital might have avoided repeated readmissions and would have been financially ahead if the patient in the first instance had remained under treatment a proper time.

In a similar instance which I have in mind the medical social worker was the first to report to the physician that a certain patient, on account of worry concerning the welfare of his family, was contemplating leaving the hospital much too soon. Through her service the family was temporarily provided for, the patient's mind was placed at ease, and his acute nephritis cleared up splendidly. Can anyone gainsay that the service of the medical social worker in effecting mental rest and co-operation on the part of the

patient was not an important feature of the medical care in bringing about that patient's recovery? Thus medical social service is directly concerned with the first duty of the hospital as outlined above, which is the care of the sick.

The second duty of the modern hospital, the advancement of medical science, is likewise interrelated with the functions of the medical social worker. The advancement of medical science depends not alone upon research work in the laboratory, but upon critical study of clinical records and case reports. As Haven Emerson has said: "Before we can claim to be developing or even protecting health we must know the sum and character of human sickness. Our first and best and perhaps our last, source of information will be the organized medical service shops, the hospitals, the dispensaries, the sanatoria, convalescent homes and domiciles of the insane, of children, of paupers, and those great institutions now infiltrated throughout the country, the visiting nurse association, whose experience and records offer often a greater range and bulk of material than the larger hospitals of a city or State all combined." It at once becomes apparent that the records of the medical social workers are important, not alone in the care and treatment of the individual patient, but from an altogether different angle, that of investigation or research. A study of these records as furnished by the numerous groups of social medical workers throughout this country will afford a great amount of material for the study of diseases from an angle heretofore little considered. And it will represent material that cannot be gotten so well in any other way.

This brings up the importance of the records kept by the medical social worker. Her record concerning the diagnosis of the patient's illness, the treatment, the follow-up notes and the final result should be carefully and accurately done. Since they may some time be used in an intensive study of economic or disease conditions in a given locality, or in many other ways, their value will be in direct proportion to the care and thoroughness that was spent in their making. When completed such a social history should be filed as part of the hospital record. In the event that the patient was not a hospital case, it should then be filed in the out-patient department, so that it is accessible to any one who may profit from its study.

For many years the average hospital required no medical history at all. But the importance of a reliable medical history is so great from so many standpoints, including the matter of research, that medical organizations are expending great effort in improving the character of those histories throughout the hospital world. And since the records of the medical social workers are likewise valuable as a part of the complete record, they should be carefully compiled. In a word, the organized body of medical social workers should realize the value of good record keeping on their part, and thus make their material available now, rather than waiting for years until some organized effort becomes necessary to awaken them to a realization of this duty.

The third duty that hospitals must assume, though many have not as yet done so, is to make themselves community centers in better health instruction and preventive medicine. And what better way is there by which a hospital may bring a community to the realization of its worth? Or bring the community to comprehend the great asset its hospital is? Up to the present some have been interested only in the patient himself, endeavoring to rid him of his disease. We are just beginning to be concerned about the members of his immediate family, whom possibly we may save from illness altogether. "Man does not live unto himself alone." And it is just as true that "if one wishes to be well he must be certain that his neighbors are well." One of the most important lessons taught by medical science has been the significance of environment and the community aspect of disease. Some individuals may have inherited certain predispositions or physical weaknesses. It is then important that all that is possible is done for his own physical well-being. In this way he may be prevented from contracting an illness, or, once the victim of a chronic illness, he may be prevented from passing it on. Greater good will result from preventive medicine, from protecting many in addition to caring for the person who is ill. To help the "other seven" is the medical social worker's problem, and if a hospital or a physician wishes to succeed in this work they must use as their assistants trained workers in this field.

In short, the time is at hand when the hospital may entrench itself firmly in its community by seizing upon this opportunity for the spread of knowledge concerning public health problems and preventive medicine. There are many ways for the hospital to go about this. One agency that can be used with greater effect than all others is the medical social worker department.

There remains the fourth duty of the hospital, the training of hospital personnel, administrators, internes and nurses, as well as medical social workers and other technicians. If hospitals do not train their employes, from whence is a supply to be obtained? And what department in the hospital is better able to train medical social workers than that department itself? The need for such work in every hospital maintaining a clinic is great. The greatest difficulty has been the backwardness on the part of the hospital authorities, often through lack of funds, to develop such a department. In answer to this, it has been shown that such a department actually saves its cost by lessening the number of clinic patient days in the hospital. The supply of trained medical social workers is limited, and any hospital maintaining such a department has the responsibility of training social workers, just as it should train the others of its personnel.

Since the medical social worker fits logically into each of the four undertakings of a hospital, it is apparent that this department should have a definite place in the hospital organization. The more prominence it is given, the greater will be

the return, not alone to the hospital, but to the community. The medical social worker offers an excellent means of obtaining and holding the community interest, because her appeal is through personal service and effort. And the interest of a community in its hospital is vital to the welfare of the hospital.

The duties of medical social workers toward hospital administration are four at least:

1. The making of social and economic diagnoses.
2. Making accurate records, including treatment and follow-up notes.
3. Saving hospital days for the institution.
4. Acquainting the community with the value of its hospital.

The making of social and economic diagnoses is an important obligation, and the hospital administration looks to the medical social worker for its accomplishment. The importance of this diagnosis cannot be over-estimated in outlining for the clinic patient his treatment and after care. It is well enough for the physician to tell the patient with cardiac disease that he must live on the ground floor and have a light occupation. But if left to the patient, nothing will result from the advice. The medical social worker, having investigated the home conditions, instructs the patient in things that especially pertain to his well-being. And through some relief agency the patient is materially assisted in getting an abode on the first floor and in obtaining light work. As a result, the patient is able to earn some part at least of his living and is not continually returning as a hospital patient.

Dispensing of material relief is not the function of the medical social worker. Combining material relief and medical aid in the same person often spoils the possibilities of the latter. The duty of the medical social worker is therapeutic. She should not lessen the possibility of the success of her undertaking by doing things which in general practice have been proven harmful. Nor should she use her time in doing things which some other organization can do better, and which is outside her field as a technical assistant to the physician.

The second duty of the medical social worker to the hospital administration is the keeping of a creditable record for the information of the physician of the work that she is doing with each patient. If she has recorded properly the social and economic diagnosis, the treatment, the progress of the patient, the reasons for poor progress if there be any, and other follow-up notes, much valuable assistance is at once available to the physician. She often finds the first information of the beginning of an epidemic of disease, and her records accumulate important statistical data. Much information may be recorded, the value of which is not at all suspected at the time the record is being made. The importance of carefully kept records and of their finally being filed as a part of the hospital record warrants a repetition of the statement made earlier in the paper, that if the medical social worker has any obligation to the hospital administration at all, it is that of turning over records which show real thought and careful work, and which will be useful to the physician.

The saving of hospital days is a third duty of the medical social worker to the hospital administration. This is of benefit as an economic measure. A patient's sojourn in a hospital may often be materially reduced as a result of the ministrations of the medical social worker. Such instances have been referred to. Or the patient's convalescence may be completed in his own home under the medical social worker's supervision, who makes contact both with the patient and the physician. In either event the hospital has a bed that may be used for other purposes.

Another financial assistance that may be rendered the hospital administration is at the admitting clerk's desk. No one is in a better position to know or to find out the financial status of a clinic patient and of his ability to pay at least part of his expense. It has often been said that the expense of the medical social department may be more than met in this way.

And finally the last, but not the least, of the medical social worker's duties toward the hospital administration is that of acquainting the public with the worth to the community of a good hospital. The medical social worker is in one sense a field agent of the hospital, and she has many opportunities to interest various groups of people in the undertakings of her institution. A hospital holding the confidence of its community stands as a bulwark against all the medical fakes and frauds that are found in California. And the opportunities which the medical social worker has to increase the confidence of the community in her institution must not be overlooked.

Medical and Hospital Work in Russia.—Moscow, July 3 (by mail)—Thirty-three physicians and surgeons, each in charge of one of the Moscow hospitals, have united in signing a letter of thanks to Dr. W. D. Nickelsen, medical supervisor of the Moscow District for the American Relief Administration. The letter follows:

"At the moment when the Moscow city hospitals were insufficiently supplied with food and other necessaries for the care and cure of the sick, the American Relief Administration came of its own accord to the assistance of those hospitals, supplying them regularly with medicines, instruments, things needed for the care and treatment of the patients, linen, blankets, gowns, and also took upon itself the supplementary feeding of the patients. This assistance has greatly improved the condition of the patients and has also helped to check disease in general.

Being aware of the great good done by the humanitarian activities of the American Relief Administration, the chief physicians of the Moscow hospitals are conveying to that organization, in the person of the chief of the Moscow section, their sincere appreciation for its present activities and its readiness to continue that work in the future."

OBSERVATIONS ON THE CARDIOVASCULAR SYSTEM IN THYROID DISEASE*

By WM. J. KERR, M. D., Associate Professor of Medicine, and GEORGE C. HENSEL, M. D., San Francisco.

The changes produced in the cardiovascular system by thyroid disease have long been appreciated by clinicians. There is need, however, to review some of the more important features observed, so that patients with grave cardiac disorders will not be subjected to unnecessary risk at operation nor will they be denied adequate treatment to support and restore the circulation.

It is our purpose to call attention to some irregularities of the heart in thyroid disease which are extremely common and which are not emphasized sufficiently in the literature. These irregularities play a considerable part in determining the outcome of the more severe cases and their recognition is not difficult.

The studies on which this report is based have been carried on at the University of California during the past two years.

GENERAL CONSIDERATIONS

Of the one hundred and eighty-one goiters studied, one hundred and twenty-three were classified as adenomas and fifty-eight as hyperplasias. In reviewing the adenomas, no attempt has been made to draw a sharp distinction between the toxic and non-toxic types. Approximately half of these cases showed no signs of toxicity and in a relatively small number the goiter produced pressure symptoms only. The average age was forty-six years and a tumor was noted at the average age of twenty-nine years, or seventeen years before appearing for treatment. Symptoms had been present on the average for eight and three-tenths years. Females were affected one hundred and six times and males seventeen times. Cardiovascular symptoms were more or less marked in forty-four per cent of the cases. Rapid and forceful beating of the heart and "palpitation" were the symptoms usually complained of, although vasomotor disturbances, irregularities of the heart, dyspnoea and breathlessness were frequently noted. Pain in the region of the heart and anginal attacks were rare. Central nervous system symptoms, including nervousness, tremors, astasia abasia and emotional instability were described in fifty-eight cases. Gastrointestinal symptoms, usually diarrhoea or diarrhoea alternating with constipation, were complained of in only four cases. There was marked progressive loss of weight in eight cases and a gain in two cases. In no case was there marked exopthalmos. When the eye changes were noted, usually only one or two of the minor signs were described. The average basal metabolic rate, when determined, was 30.2 per cent above the theoretical normal, but when the non-toxic cases were excluded, the average rate was 47 per cent above the theoretical normal. There were two deaths.

Of the fifty-eight cases with hyperplasia, forty-four presented exophthalmos and other eye signs and in five others these eye signs were slight or doubtful. The average age was thirty-six and four-tenths years and the tumor was observed at the average age of thirty-three and nine-tenths years, or two and five-tenths years before entering the hospital for treatment. Females were affected forty-three times and males fifteen times. Symptoms had been present for a relatively brief period. In about one-third of the cases, the tumor was noticed before the onset of symptoms; in about one-third the appearance of the symptoms preceded the discovery of the tumor; and in the remainder the symptoms and tumor appeared at the same time. The average duration of symptoms was about three months. Cardiovascular symptoms were complained of in 91 per cent of the cases. "Palpitation" and rapid, forceful beating of the heart were usually present; irregularities, dyspnoea, breathlessness and vaso-motor disturbances were common. Fifteen cases presented signs of decompensation. Central nervous system symptoms were present in fifty-six cases and were more pronounced than with the adenomas. Gastrointestinal symptoms such as diarrhoea and vomiting were complained of in seventeen cases. There was a definite loss of weight in thirty-eight cases. The basal metabolic rate averaged 58.7 per cent above the theoretical normal. There were seven deaths.

SPECIAL CONSIDERATIONS OF THE CARDIOVASCULAR SYSTEM

Symptoms—A brief statement of the cardiovascular symptoms is given above. It is the prevailing opinion that the hyperplastic goiter causes more profound changes in the circulatory system than is found in association with toxic adenomas. Our observations suggest, however, that, so far as the heart is concerned, the disturbances are practically the same in both groups. Where differences occurred, they seemed to be due mainly to the degree of toxicity. The vascular system, however, showed more pronounced changes in the hyperplastic group than in the group of adenomas. Among the earliest symptoms were tachycardia and a consciousness of the heart beat. Many patients complained of attacks of "palpitation." These spells, which were more frequent later in the disease, probably represent paroxysmal attacks of auricular fibrillation or flutter. Throbbing of the vessels in the neck and periphery, pulsation in the thyroid and a heaving precordium were usually marked in severe cases. Sleep was frequently interfered with because of these sensations and such patients preferred to lie on the right side. Dyspnoea and breathlessness on exertion, and in the later stages cough, progressive edema, cyanosis and other signs of decompensation were observed where proper treatment had not been instituted. Goiters producing pressure symptoms were relatively infrequent causes of cardiovascular disturbances as compared with the overacting glands.

Physical Signs—Inspection in the early cases revealed very little aside from a forceful apex impulse in the usual position, slightly increased carotid pulsations and flushing of the face and neck. As the disease advanced, the apex impulse

* From the Medical Division, University of California Hospital. Summary of paper read before the Section on General Medicine, California Medical Association Meeting, Yosemite National Park, May 15 to 18, 1922.

(Most of the patients were on the surgical service of Dr. W. I. Terry, to whom we are indebted for the opportunity of making the studies here reported.)

became more forceful with a diffuse heaving of the precordium. The apex impulse was then displaced to the left and, in later stages, downward. The carotid arteries and peripheral vessels showed increased pulsations, and capillary pulsation was frequently noted, especially in the hyperplastic cases. When the myocardium began to fail, the venous pressure rose, the veins stood out and they occasionally showed unusual systolitic pulsations extending to the lower arm and hand (noted in three of our cases). When decompensation began, the usual signs appeared: such as pulsating liver, systolic venous pulse in the neck, edema of the lungs and edema of the legs advancing to anasarca. During the stage of decompensation, the heart was frequently irregular and no sign of an A-wave could be found in records from the jugular vein. On palpation the apex impulse was usually forceful and showed no displacement in early cases; but as the condition advanced, the impulse became more marked and diffuse, and it moved to the left and downward. A systolic or presystolic thrill at the apex, or a systolic thrill at the pulmonic area was noted in a few cases. A distinct shock was felt at the pulmonic area, accompanying the second sound. A systolic thrill was frequently felt over the thyroid vessels in hyperplastic glands, rarely in adenomas. The pulse was usually soft and oftentimes dichrotic. A water-hammer pulse was common in the hyperplasias. The rate was quickened in toxic cases, being ninety-three in the toxic adenomas and one hundred and seven in the hyperplasias in our series. In the early stages the pulse was generally regular, although a sinus arrythmia of the respiratory type was frequently observed. Later, many cases showed the more unusual types of irregularities, and in the terminal stages they were very commonly observed. By percussion the heart was found to be gradually enlarged to the left and downward, there was a well defined increase in dulness in the third and fourth left interspaces, as is seen in organic mitral disease, and later the dulness was increased to the right. Enlargement, usually to the left, was noted in forty-one of the adenomas and in forty-three hyperplasias. In the absence of thymic enlargement or a substernal extension of the thyroid, the substernal dulness was found to be increased, due to the dilatation of the great vessels. Auscultation revealed the signs of an overacting heart in toxic cases. The sounds were quickened, ringing and loud, giving an impression of hurried ineffectiveness. As the condition advanced, a soft systolic murmur was usually heard at the apex and a short, rough systolic murmur at the pulmonic area. Later a loud systolic murmur was frequently heard all over the precordium and was transmitted to the vessels of the neck, with a bruit over the thyroid vessels and gland. A definite bruit was noted over the gland in thirty-three of our cases of hyperplastic thyroids and in only three of the cases with adenomas. In the advanced stages of myocardial failure a diastolic murmur was occasionally heard at the pulmonic area or a soft systolic murmur appeared over the tricuspid area. Murmurs were noted in our series in forty-three cases of adenomas and in forty-six cases of hyperplasia.

An unusually large number of cardiac irregularities were observed. Of sinus arrhythmia we have no accurate data, as its finding was considered of little significance. It was frequently observed and possibly should be further studied. Extrasystoles were observed in only nine cases and in two of these it is probable that an unrecognized auricular fibrillation was present. Auricular fibrillation was observed in twenty-nine cases, occurring in nine cases with adenomas and twenty cases with hyperplasia. In fifteen of the twenty-nine cases the fibrillation was paroxysmal in type and in several cases many attacks were observed. In eight cases auricular fibrillation alternated with auricular flutter, and in two cases auricular flutter was observed alone. Paroxysmal auricular tachycardia with a rate of one hundred and ninety occurred in one case. (See Table 3.)

These observations on the frequency of cardiac irregularities have suggested that many of the attacks of "palpitation" which patients describe are due to a disturbance of the normal mechanism of the heart beat by the inception of one of these unusual rhythms. Such attacks frequently came on suddenly and usually lasted only a short time. They were accompanied by a sense of fulness in the chest, a disagreeable, rapid, forceful action of the heart, flushing of the face and neck, and breathlessness. The termination was usually abrupt.

On questioning patients who were seen during attacks of auricular fibrillation of flutter, it was found that their sensations were the same as those experienced during the previous spells of so-called palpitation. In our opinion this shows pretty clearly that what they call palpitation is really the result of serious auricular fibrillation or flutter. We feel sure that this has not been sufficiently recognized in the past.

X-ray studies on the toxic cases generally showed the heart to be enlarged to the left with widening in the region of the conus and left auricle—the so-called "mitral type." In some cases, particularly of the hyperplastic group, the heart was of the "aortic type" with the great-vessel shadow definitely increased.

Blood-pressure determination showed in the adenomas an average of 133 mm. Hg. (systolic), 78 mm. Hg. (diastolic) and a pulse pressure of 55 mm. Hg., while in the hyperplasias the average was 141 mm. Hg. (systolic) and 71 mm. Hg. (disastolic) with a pulse pressure of 70 mm. Hg. In several cases where the systolic and diastolic pressures were high before operation, a marked fall was observed following surgical treatment. Some of the more striking examples are shown in Tables 4 and 5. In one patient with a hyperplastic goiter who had a blood pressure of 200/100 on admission, there was a fall to 178/65 after medical treatment.

Venous Pressures and Pulsations—No attempt was made to measure accurately the venous pressures, but in advanced cases the pressure in the veins was definitely increased. In three cases we observed pulsating peripheral veins in the arms and hands, which cleared up after treatment.

Electrocardiagraph and Polygraph tracings were made on most of the cases showing unusual ir-

TABLE 1

General Findings

Type of goiter	No. of cases	Sex	Average age	Average age tumor noted	Average duration of symptoms	No. with eye signs	No. with C. N. S. symptoms	No. with gastro-intestinal symptoms	Marked loss of weight	Average basal metabolism	No. of deaths
Adenomas toxic and non-toxic	123	M. 17 F. 106	41.38 yrs.	29.2 yrs.	8.3 yrs.	1 slight 6 doubtful	58	4	8	30.2% plus (all forms) 47% plus (toxic only)	2
Hyperplasias	58	M. 15 F. 43	36.4 yrs.	33.9 yrs.	3 mos.	44 5 doubtful	56	17	38	58.7% plus	7

regularities and on some of the uncomplicated cases. Twenty-five cases were studied at intervals during their stay in the hospital. In addition to the changes in rhythm noted, there were certain variations in the auricular complex which were frequently observed in more severe cases. The P-waves were widened and increased in amplitude, frequently slightly notched in Lead I and having a diphasic character in Lead III. These features were noted in ten out of fourteen cases with regular rhythm. The P-R interval was 5/25 seconds in three cases and there was an arborization block in one case. Bundle branch lesions were not observed. Right hypertrophy was shown in two cases and left hypertrophy in three cases. The T-wave, when flattened or inverted in Leads I and II, has been found to indicate a bad prognosis in accordance with the findings of Krumbhaar. In our series there were six of such cases, all showing advanced myocardial disease and, as was to be expected, two or thirty-three per cent of them died.

Diagnosis—The diagnosis of the types of goiter studied were made on the clinical signs and symptoms combined with pathological findings at operation and necropsy. The cardiac symptoms and signs were usually obvious, although careful observation and instrumental means were frequently necessary to differentiate the irregularities encountered.

Treatment—No preliminary treatment was given in the non-toxic or moderately toxic adenomas previous to operation. The patients with more advanced toxic adenomas, with signs of cardiac failure, and many of the patients with hyperplasias were given preliminary medical treatment or received medical treatment alone. Mental and physical rest was insisted upon. Bromides or quinine hydrobromate were given when indicated. Ice bags were used over the thyroid gland and heart in the more toxic cases with considerable relief from distressing symptoms. Digitalis in the form of tincture was used, when indicated, under careful supervision. In moderate doses the drug produced excellent results and was very useful in controlling and possibly in preventing attacks of abnormal cardiac rhythms, particularly auricular fibrillation. One patient died during operation, possibly from the effects of excessive digitalization with "ventricular standstill." Another death occurred from auricular fibrillation with marked signs of thyrotoxicosis developing two days after operation. Quinidin sulphate seemed to have a beneficial effect in controlling attacks of auricular fibrillation in one case, although of no great benefit in several others. Cardiac decompensation has been treated by the approved methods, although excessive purgation has been very exhausting in some cases. X-ray treatment was used in many cases of hyperplasia before operation and in a few was the only local treatment employed. Radium emanations in bare tubes of 6-10 mc. were inserted into some of the more serious hyperplastic goiters with marked improvement. (These cases are being reported elsewhere by Dr. W. I. Terry.) Various methods of surgical treatment were employed, including ligation, enucleation of adenomata, partial lobectomy, bilateral subtotal lobectomy, etc.

One of the most striking observations made in this series of cases has been the degree of cardiac relief noted by the patient after removal of an overacting thyroid gland.

Prognosis—In our series it has been demonstrated that the condition of the heart generally determined the outcome of the case. Deaths from other causes, except marked increase of toxicity following operation in severe cases, were rare. Electrocardiographic demonstration of flattened or inverted T-waves in Leads I and II have indicated an unfavorable outcome. Heart block and disorders of the cardiac rhythm have been noted in the more severe cases. Signs of decompensation and advancing edema have indicated prolonged medical treatment or radio-therapy. Embolism and coronary disease were rare. Focal necroses of the liver and pancreas followed operation in one case and caused the death of the patient.

Mortality—In our series there were nine deaths, seven occurring in cases with hyperplasia, one with a mixed gland and one with an adenoma of the plunging type. In six of the nine cases death would be attributed to cardiac disease. In one of these there was embolism of the right subclavian artery. One patient had frequent attacks of angina pectoris and paroxysms of auricular fibrillation. In four cases auricular fibrillation was present at some time while under observation. Three cases presented unusual liver findings at necropsy and will be reported elsewhere at a later date. Two of the patients received medical treatment only.

CONCLUSIONS

The cardiovascular changes in thyroid disease are progressive, and in the most severe cases dominate the clinical picture.

The cardiac signs and symptoms in toxic adenomas and hyperplasias differ only with the degree of toxicity. The vascular changes are more marked in the cases of hyperplastic goiter.

Cardiac irregularities are more common than is generally recognized. Auricular fibrillation or auricular flutter, usually paroxysmal in type, occurred in about a third of all toxic cases. We believe that such paroxysmal attacks explain the periods of palpitation which are described by a large percentage of patients.

The prognosis depends in a large measure upon the condition of the circulation. If surgical treatment is to be carried out, the "time and extent of the operation should be governed by the circulatory condition."

Treatment of the thyroid heart depends on the stage of the disease. In all cases every measure should be employed to relieve the myocardium. Rest is essential. Sedative drugs are of some value. Elimination should be kept up. Digitalis is of great value in controlling auricular fibrillation and may be of value in preventing paroxysmal attacks. The amount required in controlling auricular fibrillation is usually less than in ordinary cardiac cases. It should be continued over long periods. Decompensation should be treated as in other myocardial cases.

The electrocardiogram is of value in recognizing myocardial changes in differentiating the types of irregularities and in prognosis.

STUDIES IN URETERAL CATHETERIZATION. PRELIMINARY REPORT *

By HENRY A. R. KREUTZMANN, M. D., San Francisco

Catheterization of the ureters is often accompanied by severe pain, hematuria and sometimes even by temporary anuria. In performing catheterization at the present time, it is customary to insert the catheters the entire length of the ureters so that the distal ends enter the renal pelves. This is done in order to minimize the leakage of urine into the bladder and to prevent the catheter from being pulled out of the ureter on withdrawing the cystoscope from the bladder.

This study was undertaken in an attempt to determine whether or not the present disadvantages of ureteral catheterization could be overcome by inserting the catheters only part way into the ureters. The problem has not been solved but the investigations have brought out some interesting facts.

The technic used is as follows: The patient was subjected to catheterization three times, with an interval of one week between each operation. No. 6 ureteral catheters were used throughout. At the first sitting they were inserted five centimeters into each ureter, the second time fourteen centimeters and the third time the full distance into the kidney pelvis. One cubic centimeter of phenolsulphonphthalein solution was injected intravenously with a record syringe after the catheters were inserted. None of the patients were given water to drink after receiving the phthalein.

The appearance time was noted and two fifteen-minute specimens of urine were collected from each side. The cystoscope during this time was not removed. At the end of the half-hour test, with the catheters still in situ, the bladder was washed through the cystoscope until the irrigating solution failed to show a trace of phthalein. At the same time the position of the catheters was verified by looking through the cystoscope. The three distances chosen for inserting the catheters was with the intention of having their tips each time past one of the three anatomic points of constriction of the ureters. A Dunning calorimeter was used to make the phthalein determinations. The subjects used in this study had no known pathological condition of the kidneys, ureters or bladder, with the exception of two cases which had been treated previously for pyelitis.

The following points were noted at each level: the character of the urinary flow from the end of the catheters; the presence or absence of pain, haemorrhage and anuria; the appearance time of the dye; the amount of phthalein obtained from the catheters from the right and left kidneys over two fifteen minute periods; the entire amount of phthalein eliminated in half an hour and the amount of bladder leakage.

It soon became apparent that the same person did not excrete the same amount of dye at each of the three tests, therefore the bladder leakage was figured not in the percentage of phthalein which the calorimeter showed, but in percentage of the total elimination for half an hour. As was anticipated, the farther the catheters were inserted into the ureters, the greater was the likelihood of having pain, haemorrhage and anuria. It always has been a mooted question whether or not the insertion of ureteral catheters has a stimulating or a depressing action on the kidneys. In our series of twelve cases, the average appearance time was less at five centimeters than at the other two levels. The total average phthalein output was less when the catheters were inserted their full distance than at five and fourteen centimeter levels. These two facts point to an inhibiting and not to a stimulating action of the catheters. In six of the twelve cases, with the catheters inserted five centimeters into the ureters, the phthalein leakage varied between 14.7 and 69.8 per cent. In the other six cases there was only a trace. Because of this great amount of leakage in half of the cases, accurate determinations of relative kidney function cannot be obtained when the catheters are inserted only a short distance into the ureters.

Contrary to all expectations, the amount of leakage did not decrease at the higher levels, but on the contrary, it increased progressively. It appeared that once the resistance of the first point of constriction, namely the uretero-vesical sphincter, was overcome, there was nothing to hold back the leakage. For example, Case IV showed no leakage at five centimeters. At fourteen centimeters the leakage was 8 per cent and at the full distance, the leakage was 42.8 per cent. This progressively increasing amount of leakage was constant throughout the series, with the exception of three cases. One of these three, and the only one in the series, showed a trace of leakage at all three levels. The other two were the cases which had been treated a short time before for an infection of the kidney pelvis.

From the information obtained in regard to the leakage, it appears that the only constriction of importance is the one at the junction of the ureter and the bladder, and that the passage of a medium sized catheter causes a passive dilitation of this sphincter. These facts are of practical value in comparative kidney tests, in pyelography and in pelvic levage. If it is necessary to repeat the comparative kidney function it should not be done until sufficient time has elapsed for the uretero-vesical sphincter to regain its tone.

Pyelography, when necessary, should be performed at the same sitting in order to have the minimum of leakage and insure a clean cut shadow of the kidney pelvis. When, as at present, pelvic levage is performed two and three times a week, we believe its chief value lies in the dilatation and free drainage which is produced, and not in the bactericidal action of the drug used.

SUMMARY

In ureteral catheterization, the occurrence of pain, haematuria and anuria increases in direct ratio to the distances which the catheters are inserted.

Catheterization as at present performed has most frequently a depressing action on the kidney function.

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

Accurate information as to relative kidney function cannot be obtained if the catheters are inserted only a few centimeters into the ureters.

The only constriction of importance in ureteral catheterization is the one at the junction of the ureter and the bladder.

Passage of a medium sized catheter causes a passive dilitation of the uretero-vesical sphincter which lasts at least one week.

Repeated catheterization causes still greater dilitation of the sphincter with a further increase in the amount of leakage.

The points brought out in this study are of value in comparative kidney tests, in pyelography and in pelvic levage.

SUMMARY OF THE TWELVE CASES INVESTIGATED

Distance Inserted	Pain	Haem.	Anuria	App. Time Min.	R. K. L. K. Leakage	Bladder Leakage Per Cent

The Maternity Welfare Law—"We are glad that a paper on this important topic is to be read at our annual meeting, because renewed interest has been interjected into its study by the recently expressed opinion of the Attorney-General of Massachusetts that it is unconstitutional. Leaving this for the Bench and the lawyers to decide, our attention is seriously called to a study of what appears to be another blow on the entering wedge of state medicine started by the Narcotic law. If we permit our rights to be infringed repeatedly, we shall fall ere long into the degraded condition of the profession in foreign lands. . . . Some readers of the law claim that they do not see any harm in it, whilst its opponents want to know if there is any good in its provisions. They do not see how maternal mortality can be prevented or infantile care advanced by mere political investigations. They think that the attending physicians know more about their patients than the best of officials. Some say that it is dishonest for some States to steal from others, or to utilize for the benefit of their expectant mothers and newborn infants money extorted by taxation from neighboring States, as this law directs. . . . It is said, additionally, that the death rate in infants under one year of age is greater in Biddleford than in any city in the nation. If so, at whose door is the fault to be laid? It would seem better to save these infants first, and to print statistics to be forwarded to Washington afterward. It is said by friends of the law that there will be no house visitations and therefore no interference with our practice. If, however, there is no penalty attached to such visitations, they will soon be made, because they are indispensable to investigating studies to be sent to Washington. So, too, all laws can be amended, and when it is found that without visitations nothing is gained, amendments will make them compulsory. Our State Board of Health is not so overburdened with work that it cannot study maternal welfare right on the spot, and fully as well as when supervised at Washington. It is a confession of our weakness and imbecility to ask outsiders to do our medical preventive work."—(Maine Medical Journal, June, 1922.)

THE TREATMENT OF HYPEREMESIS GRAVIDARUM*

By G. CARL H. McPHEETERS, M. D., Fresno, Cal.

As shown by the title, it is not the purpose of this paper to classify the toxemias of pregnancy, or to theorize regarding their etiology. It is merely intended to pass on to the profession what has been learned from practical experience in attempting to control what De Lee styles "the obstinate, the uncontrollable, the incoercible vomiting of pregnancy." The excuse for the paper, if any were made, lies in the fact that about one-half of all pregnant women suffer with nausea and vomiting during pregnancy. So common is it that the mass of the laity regard it as a normal accompaniment of pregnancy and do not know that any therapeutic relief can be obtained. How frequently one sees the expectant mother struggle in vain in the latter half of pregnancy to regain the flesh and blood she lost because of nausea and vomiting during the earlier months.

In considering the treatment, it is the practice of the writer to differentiate as sharply as possible between the mild and the severe type of vomiting in pregnancy. Suffice it to say that by the severe type is meant the toxemic, or dangerous and frequently fatal type. Every patient reporting nausea or vomiting should be treated at once, even though her nausea is of the mild type, because one can never know beforehand that the mild type may not grow rapidly worse at any time and become toxic. Also, most observers agree unanimously that the nausea and vomiting of pregnancy yields best to immediate treatment and is less easily handled if there is delay in beginning remedial measures.

The treatment usually given to the mild type case is as follows: The patient is not kept in bed unless she is one whose nausea borders upon the pernicious, or toxic type. Every patient is requested to present a specimen of vomitus at the office for inspection and analysis, if practical.

An initial catharsis, consisting of calomel, gr. 1 to 1½ in ¼-gr. divided doses followed by magnesium citrate, oz. viii, is administered. The patient is advised to take the calomel in the forenoon and the magnesium citrate solution just before lunch or early in the afternoon of the next day, whichever suits her best. Patients not usually nauseated the first thing in the morning may take the calomel in the afternoon and the magnesium citrate solution on waking the next morning, an hour before breakfast.†

A few patients dislike magnesium citrate solution, but tolerate magnesium sulphate solution, one ounce following the calomel tablets. Some

* Read before the Sections on Obstetrics and Gynecology of the Medical Society of California, at Yosemite National Park, May 17, 1922.

† It is found that magnesium citrate solution is often tolerated best by the empty stomach when taken hot. The patient is instruced to open the bottle of magnesium citrate solution, pour the contents into a large, thin drinking glass and set the glass in hot water until the solution is as hot as can be taken readily. Patients are warned never to set the unopened bottle of solution in hot water, since an explosion may result either before or at the time it is opened. The escape of gas from the magnesium citrate solution on being heated in an open glass does not seem to lessen its cathartic properties.

patients who can not tolerate saline laxatives can use phenolphthalein quite successfully; others can use the combined calomel and phenolphthalein wafers with good results. Some initial enemata of plain boiled water containing soda bicarbonate 5 per cent are given before the calomel and saline laxatives. Patients reporting bile in the vomitus and whose specimens of vomited material show bile require this catharsis especially. In them also it is necessary to repeat the calomel and saline laxatives every second or third day to keep the bile moving onward rapidly through the intestine. Only when two or three days pass without vomiting may we safely forego laxatives for a few days. When a laxative is needed again it may be possible to use aromatic fluid extract of cascara, one to four teaspoonfuls at night, instead of the calomel and salines. Any subsequent vomiting of bile calls for a repetition of the small doses of calomel and the saline following. On days when no laxative is taken a cleansing soda enema should always be given at an hour best suited to the patient.

In the matter of diet every patient is a unique case. She has usually discarded most of the heavier foods before visiting the physician. In general, meat, cheese, eggs, beans, peas and other heavy protein foods should be eliminated at once. Also pastry and sweets, raw fruits and raw vegetables are forbidden. Those patients who retain one or two meals each day are instructed to take cereals with a little sugar and cream, milk, buttermilk, toast, crackers, the non-acid vegetables well cooked, and the mildly acid fruit juices from canned or freshly cooked peaches, pears, prunes or figs. Small portions of all foods are better tolerated than large portions. Patients who vomit breakfast only are instructed to omit breakfast at its usual hour and eat a light meal two or three hours later. Those who are hungry upon the limited fare allowed are told to take something, if only a glass of milk, or buttermilk, and a cracker every three or four hours. Five or six small meals daily are usually handled better than three larger meals. All the patients are instructed to drink two to eight quarts of measured water daily, depending upon the season of the year. Milk is best tolerated when diluted with lime water half and half. Also in this way some calcium is supplied the patient. Buttermilk, either plain or with the addition of a little sugar, or salt, is tolerated by some who can not take sweet milk; also freshly coagulated (clabbered) sour milk with a sprinkling of sugar is relished by an occasional patient who dislikes fresh milk. Bouillons, chicken broth with rice or barley, lamb broth, baked potatoes, spinach, fresh or canned, tender chicken, white fish, such as halibut, are gradually allowed to the patient who has ceased vomiting for one week. The patient must co-operate by adhering strictly to her diet schedule. Written instructions from the physician are indispensable.

Regarding medicines, few are given by mouth, except laxatives as outlined. Those having marked hyperacidity persisting after free catharsis are given a capsule containing extract nux vomica gr. 1/6, rhubarb gr. ½, soda bicarb. gr. iii and magnesium oxide gr. ii, one, two or three capsules before or after meals, which are usually retained. When capsules can not be swallowed, or retained, the above prescription may be given in liquid form, using three to five drops tincture nux vomica instead of the extract nux vomica. In addition to lime water given in milk, lime may be given by mouth in the form of the liquid hyposulphites of lime and soda to which is added Fowler's Solution in three-drop doses for the anemia. Calcium may also be given the patient subcutaneously in the form of Locke's Solution, if thought desirable.

As a routine, the writer is trying soluble extract corpora lutea, 1 cc. ampules injected in the median bacillic vein near the elbow once or twice daily. In more severe cases 2 cc. of the corpora lutea ampules are injected twice daily. From one to two dozen ampules are thus injected during the first three weeks after the patient presents herself. The extract corpora lutea may be injected in the gluteal or thigh muscles in patients not having accessible veins, but the preparation is irritating when used in the muscle. Whether the action of extract corpora lutea is suggestive, as De Lee supposes, or whether it does supply what the corpus lutem of pregnancy does not supply, as Hirst believes, is not known or proven. The writer, however, has no doubt of its definite value in scores of cases of hyperemesis gravidarum, in many of which it was the only treatment given. Further proof of its value is seen in those patients whose treatment with extract corpora lutea was interrupted after they had ceased to vomit for some days, but before they were well enough to eat a full diet. These patients invariably resumed vomiting and required one-half to one dozen or more injections.

It is well to warn the patient who has just ceased vomiting and begins to have some appetite that she must continue treatment until able to eat a full diet in order to be reasonably safe from disappointing relapses. Such relapses may carry the patient over into the class of severe or toxic cases. For anemia these patients are given iron and sodium cacodylate in addition to the Fowler's solution previously mentioned. Iron cacodylate, 1 cc., is given in the vein or in the muscle daily or on alternate days, as best tolerated. One to two dozen injections of iron cacodylate are given. The more anemic patients should also receive ½ gr. sodium cacodylate, alternating with the iron cacodylate. Most gratifying improvement in the red blood count, the hemoglobin and the blood pressure will occur within a month after the patient presents herself. Patients having focal infections will show less rapid blood improvement.

The eradication of focal infections is the most vital part of the treatment of hyperemesis gravidarum. The patient and her family often object to this most seriously, and it should not be undertaken lightly by the physician. Co-operation of a competent nose and throat specialist and a dentist, whom the patient trusts, is indispensable. Radiographs of all the teeth are made as a routine. Cultural evidence from nose and tonsilar crypts

is often of service in showing the patient that serious infection exists. In the routine search for foci of infection the ear, the cervix uteri, the anal margins, the urinary tract and Bartholin's and Skeene's glands should not be overlooked.

In the practice of the writer more than half of all patients who vomit in pregnancy exhibit focal infections; and of those having focal infections nearly all are found to have pathogenic bacteria in their catheterized urine. The co-operation of the urologist is of immense value in these cases.

The proper time to remove foci of infection in the nauseated patient is the first day when her condition will safely permit the procedure required, or as soon as her consent can be obtained thereafter.

The above treatment shortens the mild type of vomiting in pregnancy from its natural duration of two, three or four months to one, two or three weeks in most cases. It is unusual for any vomiting to occur after the second week. Treatment is usually continued four or five weeks in order to prevent relapse.

In considering the treatment of severe or toxic type of hyperemesis gravidarum, no description or attempt at classification will be set down here. These patients are invariably kept in bed. Those having a frank nephritis with or without hypertension, especially when the nephritis is accompanied by cardiac decompensation, should receive therapeutic abortion. Also the occasional patient who is tuberculous should be aborted without effort at other treatment for her vomiting. Patients showing no nephritis or tuberculosis have an encouraging outlook.

After the patient is secluded in a quiet room in her home, in a maternity, or, best of all, in a hospital, she is at once given extract corpora luteum, 1 or 2 cc., twice daily in the vein. The next step in treatment is the administration of copious sodium bicarbonate enemas. After an ordinary cleansing soapsuds enema has come away, two quarts of hot alkaline solution are administered slowly with a long colon tube, the patient in Sim's position on her right side. She is urged to retain as much of this as possible, just as long as she can. This is repeated night and morning for two or three days, longer if it can be tolerated by the bowel. During the first twenty-four hours a vigorous scrubbing of the teeth and tongue with the toothbrush is in order, using hot soda bicarbonate solution as a mouth wash. The foul taste in the mouth and offensive odor of the breath are often relieved at once. Severe cases often have an acetone odor to the breath, which persists until the patient begins to assimilate some nourishment. After the first day of fasting and enemas, the nurse offers the patient 8 to 12 ounces hot 5 per cent sodium bicarbonate solution on waking in the morning each day. This is commonly vomited, the vomitus containing a little bile-stained mucus. After vomiting the soda solution the patient should suck a ¼-grain calomel tablet and remain absolutely quiet for one hour. Then hot lime water, ounces 2, containing fresh whole milk, ounces 1 or 2, or malted milk, 1 teaspoonful, is offered to be sipped slowly through a tube without moving in bed. Some patients tolerate this better when given ice cold, especially in warm weather. Part or all of this may be vomited. It is surprising to everyone how often it is retained. Later in the day the lime water and milk may be repeated, or plain lime water containing the beaten white of an egg and a few drops of lemon juice. After two or three days of this the patient is placed gradually on a three or four hour feeding schedule, ounces 4 to 6 of lime water and milk mixture being most often given. Albumin water is better tolerated than plain water and quenches the thirst. As it is tolerated the milk may be increased until ounces 2 to 4 each of milk and lime water constitute a feeding. This point is sometimes reached in three to five days, the patient continuing to vomit once or twice daily, however. After two or three days' treatment a laxative must be tried. For this purpose ¼-gr. calomel tablets are given during the day, 1 gr. in all, and phenolax wafers, 3 to 6 in the evening. The results are uniformly satisfactory next day. After free catharsis the patient's fever often disappears and she feels much better.

The most severe cases will require gastric lavage with the stomach tube daily for many days before they can retain anything by mouth. After such lavage it is wise to deposit olive oil, ounces 2, containing castor oil drams 4, in the stomach, or a simple saturated magnesium sulphate solution, ounce 1, well diluted.

In the severest cases also rectal medication is often effective. After the usual morning soapsuds enema for cleansing, ounces 4 to 6 of hot water containing chloral hydrate, gr. 10, sodium bromide, gra. 20, and sodium bicarbonate, grs. 30, is deposited high in the bowel with the colon tube. The patient is admonished to lie quietly and retain it. This may be repeated at bedtime. Often the patient will obtain the first restful sleep in many days after this medication. In those cases suspected of having a thyroid deficiency large doses of thyroid gland may be administered in the above rectal medication. Feeding may also be carried out to a very limited extent per rectum, the most useful things being glucose solution 5 to 15 per cent in a small amount of milk. Both rectal medication and feeding are limited to use for three to five days only because of a gradually increasing irritability of the bowel. The occasional patient who dislikes milk in any form is a unique problem when vomiting in pregnancy. For her malted milk can be made up with water in place of milk, also malt soup, potato soup, pearl barley soup, albumin water or ice water, cereal gruels, cocoa and tea are useful, with lime water whenever it can be introduced. Calcium may be administered to these patients in the form of Locke's solution subcutaneously once or twice a day. Patients having extremely scanty urine are greatly benefited by the Locke's solution and also by physiological salt solution, if one is sure there is no nephritis. After one, two or three weeks of the above treatment, the most severely toxic patient is generally able to eat one or two light meals each day and retain them. The occasional hopeless case is apparent after one week

of faithful effort upon the part of nurse and physician.

CONCLUSIONS

The importance of hyperemesis gravidarum is urged by the writer because of the fact that one-half of all pregnant women suffer from it.

For purposes of treatment, the simple differentiation between mild and severe or toxic cases is sufficient.

All nausea and vomiting of pregnancy, however mild, should be treated carefully in the hope of preventing the development of pernicious or toxic vomiting with its terrible results.

The treatment of the mild type may be carried out in the physician's office, or in the home of the patient.

The treatment of the severe or toxic case should be carried out in a maternity, or a hospital, and the patient's family should be given to understand the gravity of the condition and the necessity for the utmost care.

An earnest appeal is made to the profession for more detailed attention to the treatment of hyperemesis gravidarum.

(1021 Mattei Bldg.)

DISCUSSION

L. G. McNeile, Los Angeles—The last thing that Dr. McPheeters said in connection with fifty per cent of all women having hyperemesis gravidarum I may have misunderstood. I think that is a mistake because hyperemesis gravidarum is toxic vomiting and we believe that fifty per cent of all pregnant women do have some vomiting, but we do not believe that they have toxic vomiting. I would say closer two, three, and the highest five per cent. We believe from our results in the South that you will get some results in about fifty per cent of cases if the patient is not a toxic case, by the use of corpus luteum as the Doctor advises. Fifty per cent of our toxic cases do not respond to corpus luteum by mouth or hyperdermically. In our toxic cases of vomiting we feel the importance of a patient fasting not less than seventy-two hours. Put the patient on sodium bromide by drop method, nothing by mouth, and give cleansing enema once or twice daily. We are very much interested at the present time in results of Titus' investigation regarding the use of glucose in various toxemias of pregnancy. I have used it in a few cases. Titus has published in the Journal of the American Medical Association of January, 1922, a series of approximately 150 cases of true pernicious vomiting, confirmed by laboratory examinations in which he only had to abort one case. Intravenous use of glucose has given good results in our hands. Only few have been tried but they seemed to confirm his results. Dr. McPheeters' paper shows a world of work and I wish to congratulate him for what he has done.

H. A. Stephenson, San Francisco—I haven't seen as many cases of pernicious vomiting as I would like to from a standpoint of experience, but I have not followed the line of treatment as outlined by Dr. McPheeters. I belong to that group that is somewhat at variance with his method of treatment in regard to diet. My experience is that, certainly 72 or even 120 hours of absolutely nothing by mouth gives better results in severely toxic cases than attempting to give them especially liquid or soft diet. It doesn't seem that it is very difficult to have soft or liquid diet returned, but it does seem to me that there is considerable more difficulty in having the patient bring up heavy foods such as outlined by Lynch in his treatment in this type of case. In all of my cases who have been very sick, as confirmed by laboratory tests, we have found that absolutely nothing by mouth, isolation from the patient's family immediately, under the strict supervision of a nurse, with perhaps the offering of food around the fourth or fifth day, meets with better success than trying to give liquid or soft diet. One interesting case has been aborted eleven times for pernicious vomiting, not by me but by other doctors. In spite of her repeated hyperemesis, laboratory tests did not show any toxemias. We believe that she was neurotic, because a great many of these patients do get the habit. One thing leads to another and soon the patient believes she cannot retain any food. After not allowing her to have any food for four days she asked the nurse for a hot water bottle. When the nurse removed the hot water bag, the hot water was gone. She was able to retain more or less of the hot water and after that we had no trouble. She gave birth to her first baby with her twelfth pregnancy. That may be an extreme case, but I do believe that fasting which Dr. McNiele has mentioned, with bromides rectally and alkaline and sugar solutions, we have used lactose rather than glucose, has given satisfying results. As to drugs in the mild cases, I have not been using the treatment outlined by Dr. McPheeters, but I have combined chloral hydrate, codeine, and extract of belladona, which we have found to be the most efficient of all drugs to be used by mouth. Corpus luteum given intravenously will give results in about one-half of the cases. I think with De Lee that a good many of the mild cases are pure neurotics and that may be demonstrated by the fact that a patient who says she can retain nothing when suddenly taken to a hotel and set before a big meal will be able to retain it. It is rather embarrassing not to retain it. Therefore, I believe that the way to treat these cases is by isolation, especially from the patient's family, strict supervision professionally, with treatment per rectum with alkaline and sugar solutions, generally is preferred until we determine after four or five days whether it is a true toxic case. The only treatment for true toxic cases, I believe, is a therapeutic abortion.

Margaret Schultze, San Francisco—At the University of California our treatment consists of isolation of the patient from her family cares and duties and placing her under the care of a special nurse. Nothing is given by mouth for usually 24 hours after the last time that she vomits, ordinarily that is about 48 to 72 hours. She is given at that time glucose and soda by rectum and is given large doses of bromides. Bromide is the only drug ordinarily used. The diet is then gradually begun 24 hours after the last vomiting and consists ordinarily of meat. Ordinarily, the first thing that is given is very hot steak, a small portion which is freshly cooked, and very hot. The patient is given at this time, also, some very crisp, dry bread, toasted, and is given a small amount of milk and cream. It is insisted very firmly that she must take all of this diet or she cannot have any. She is not allowed to choose. The psychic control is a very important feature. She must be made to understand that it can be controlled. At the beginning the diet is given usually about four times a day in small amounts and gradually increased. Acid fruits and acid vegetables are not added at any time, but certain vegetables may be given later on, green vegetables particularly. Results have been remarkably good. I have seen a great many treated and very few have not responded very quickly. In very severe cases abortion must be undertaken early.

Hamilton, Oakland—In January I had a patient to whom I gave corpus luteum, to which she responded. She vomited again and I again gave her corpus luteum and she once more responded. The next time I saw her personally, I gave her corpus luteum hyperdermically, intramuscularly and intravenously, and she came around a

little. A week before I came up here she began to vomit and again I gave her corpus luteum. We dilated the cervix enough to introduce a soft catheter equal to a colon tube, which turned on itself and was packed with gauze for twenty-four hours. Her blood count showed 17,800 white cells. The temperature was normal, 99, and pulse 100. Urine had X albumin and XXX casts. On the second day she had XX albumin. Three different urinalyses were done. She steadily improved from the time of putting in this large tube and we then gave her soda bicarbonate and glucose. I think there may have been some scar tissue in the cervix.

A. L. Munger, San Francisco—Dr. McPheeters mentions anemia. I do not know whether it is because in the last few years we have been making more careful examination of the blood or not, but at least the last couple of years I have been tremendously impressed with the pregnancy cases that were running a haemoglobin of 70% or under. I, like Dr. McPheeters, have gotten some very good results with the use of arsenic, but now use more Fowler's solution. With reference to infection, last year we had in the Clinic a U. C. man by the name of Dr. Nobbs who went over our patients' teeth very carefully. A large number of these were having difficulties of one sort or another. They got a tremendous amount of relief by having their mouths cleaned up. A large large number was also referred to the Nose and Throat Clinic. Occasionally one will find that these patients have cervicitis. Focal infection is something that should be seriously considered. In regard to my experience with corpus luteum, I have not had very good results in this respect. I would like to hear what somebody else thinks about it. In the majority of patients that I have given corpus luteum I have knocked the systolic blood pressure down to 100 and the patients have been so miserable from the hypotension that they were worse off than with their vomiting and refused to take any more corpus luteum.

I am tremendously interested in sterility, because it is a known fact that the native American woman is bearing fewer and fewer children as the decades go by. If she continues in her present rate of decrease, there will be no children born after a few more generations, and therefore I am interested in increasing the birth rate in California. We should do anything we can in the medical profession to encourage women to bear children. My paper last year at Coronado was designed for that purpose. I think if we can save babies from needless sacrifice and every woman from needless suffering during pregnancy we shall do a great deal to encourage the birth rate in California and in other States.

It is my belief that all vomiting of pregnancy is a toxic thing. I don't think there is any difference between the mild type and the severe type except in severity. I don't think there is any difference at all in the chemistry or biology of the thing except in the degree of severity. That all vomiting is toxic is my firm belief, and I think it will be proven. Those gentlemen who discussed the paper believe that 50 per cent only respond in general to corpus luteum. I think in many cases they did not give enough corpus luteum. I thought corpus luteum was of no value myself when I began using it, because I was content with giving half a dozen injections, and if the patient did not vomit for a day I stopped giving it and thought she was well. You must continue to give large amounts. If it reduces the blood pressure do not be discouraged: it will come up if you correct your anemia. In my cases, now numbering 1,000 (just before I came up to this meeting I passed the one thousandth case), in the treatment of hyperemesis gravidarum of pregnancy, or if you wish to call it something else, in the nausea and vomiting of pregnancy, in those I believe I have gotten 80 per cent of benefit from corpus luteum. I won't say that is what cured the patient or remedied her permanently, but I will say it benefited her because the other treatment was used along with it in most of the cases.

I regard the use of sodium bromide as excellent, but I would like to inquire of the gentlemen, why starve the patient two or three or four days longer? It has been my experience that the pernicious vomiting case has usually been starved pretty thoroughly for one week or two before she calls to see me. I tell the patient to call me at once the first day she is nauseated, but they will wait two or three weeks and vomit until they have an acidosis, if you please, and I inquire why starve them any longer? There is nothing in the stomach but mucous and bile: the patient has a fruity odor to the breath; she has lost from twenty to thirty, and in one case, thirty-nine pounds in the two weeks previous. Shall we starve her four days more? Let us begin to feed her something right away. She has dried out her body of all its fluids until her haemoglobin test is lowered and the viscosity is greatly increased. I think it is important to feed that patient liquids and as soon as possible solid foods. I like very much the remarks of the doctor on the psychic control of her patient, but I could not, for want of time, say anything about that, but it is well known that many of these cases would vomit from psychic causes and can be controlled especially by suggestion.

I am sorry that I cannot answer the question of Dr. Hamilton regarding scar tissue of the cervix. I think some one of the gynecologists could answer that.

Some Comparative Results in Cities and in Counties as Health Units—The fundamental principles involved in the prevention of typhoid fever, A. J. Warren, Topeka, Kan., says, are the same for the country as for the city, and they are the same the country over. The same is true of smallpox, diphtheria, infant mortality, and other diseases concerning which we have fairly accurate knowledge. The only difference is in the practical application of the fundamentals involved to the given area. And even here differences are apparent only in the execution of the details, and are not general. Natural factors also favor the country dweller, and the present conditions are a reproach to our lack of efforts and intelligence. An effort was made to determine the relative cost of, and effectiveness of, public health work in urban and in rural communities. A survey covering three cities and nine counties, all having well organized health departments, was undertaken. The evidence submitted proves, conclusively, nothing. It does, however, suggest that the charge that rural health work is more expensive and difficult than urban health work needs modification, if not a complete withdrawal.—Journal A. M. A., July 29, 1922.

EDITORIALS

NEW OFFICES OF THE STATE SOCIETY

The Society was notified on July 11, 1922, by the agents of the Butler building that the rent would be materially increased, and in order that the present offices might be held a lease for three years would have to be signed (in our case) by individual doctors. The general counsel for the Society refused to give his permission for the signing of such a lease by individuals, and, inasmuch as the lease could not be signed, the Society was compelled to look for other rooms.

Suitable offices have been found in the Balboa building, rooms 1015, 1016 and 1017, at Second and Market streets, just below the Palace Hotel, where it has been found that three rooms will suffice—four being occupied in the Butler building—at a material reduction in rental. In the new offices it will be feasible to use one less telephone than we are using at present, so that the move from all standpoints is advantageous, as the League for the Conservation of Public Health is at present located in this building because of the same circumstances.

THE PHYSICIAN AND "PRIVILEGED COMMUNICATIONS"

The confidences between patient and physician in all countries and in all times have partaken somewhat of the confessional. In most civilized countries and in practically all so-called non-civilized countries these confidences have been and are respected by law. In some of the States of the United States a physician is not permitted to testify as to knowledge obtained in his professional capacity. In other States and in other countries only certain classes of information are covered by the "privileged communication" provision of the law. In a few cases privileged communication is not recognized and physicians are required to testify regardless of the injury that such testimony may do to patients and family and regardless of the manner in which their information is received. This problem in general has been very well taken care of until the last few years. The development of State medicine and socialized medicine in its various forms struck a great blow to privileged communications between physician and patient. This is well illustrated in the Workmen's Compensation and Industrial Insurance Acts in various States. Other laws have been passed, one after the other, which in the aggregate have constantly restricted privileged communications, confidences that should be sacred between the sick patient and the physician. One of the latest inroads into this sacred covenant has been found in Great Britain, where it is generally known that State Medicine is in full bloom, so full in fact that most of the attractive petals are withered and falling from the flower. The British Medical Association in its recent convention condemned the destruction of the principle of the sacred covenant between patient and physician in measured terms. They recommended passage of legislation restoring to physicians of Great Britain the right to receive the confidence of their patients and to keep such confidences inviolate.

The Anti-Vivisectionists—The anti-vivisectionists are at it again. They have an initiative measure on the ballot this fall under which you may not perform an experiment on an animal, even under anesthetic or without pain, if the purpose is scientific investigation, but you may cut an animal open, mutilate or burn it, painfully and without anesthetic, if the purpose is convenience in farming. The law expressly says both of these things, in direct language. Animals may be caught alive, in steel traps, or shot and wounded, for sport or profit; they may be killed for food, painfully; they may be branded with hot iron, to identify them as property, or dehorned, gelded, spayed, castrated or caponized, without anesthetic, for convenience or luxury, and there is no law against it. In fact, these farming operations are expressly permitted, in this language, by the law. But the surgeon with a delicate and perhaps new operation to perform may not perfect his technique by doing it first on an animal, even under complete anesthesia. No drug may be tested, by administering it to an animal, first. No serum, to protect children against diphtheria, or even to protect other animals against anthrax or hog cholera, can be manufactured or tested.

A human being bitten by a mad dog must die of hydrophobia since the only known treatment involves inflicting a needle-prick on a rabbit, and this is forbidden. The botulinus investigations, without which the California fruit-canning industry would be ruined, are forbidden. It is forbidden to investigate the poisoning of orchard pests or their extermination by their natural enemies, or even to make experimental investigation of the diseases of plants. Present methods of combating anthrax and hog cholera are made penal offenses, and the treatment of diphtheria, lockjaw and meningitis by the methods approved by modern science are forbidden. The teaching of medicine, physiology and biology in the universities of California is made impossible. And a thousand other things, equally absurd.

And all this, not to protect animals from pain—since animal experimentation is prohibited even when there is no pain, while the infliction of pain is permitted, if it is for other purposes—but to prevent scientific investigation.

The thing is almost unthinkably preposterous. No such law exists or has ever been seriously proposed in any civilized country. And yet there will be a real crusade for it, by people who think they are sincere, in California.—Chester Rowell, in S. F. Bulletin.

NEW MEDICAL JOURNAL

A new medical Journal, known as the "American Medical Press," a monthly medical publication, came off the press in June. This Journal emphasizes the importance of medical economics and the duty of the physician as a citizen. Dr. F. H. McMechan is editor; Harvey S. Knox, business manager. The Journal is published by the New York Press, 280 Broadway, New York City.

Thank You—Dear Doctor Musgrave: Just a note to congratulate you upon having accomplished the Herculean task of shortening the papers in the California State Joournal. I think it must increase the interest in the Journal, and it will enable many more to be heard when they want a hearing. I noticed a while back one of the Canadian Journals has a large number of articles, all about a page and a half long.—Walter C. Alvarez

STATE SOCIETY

CODIFICATION OF THE CONSTITUTION AND BY-LAWS OF THE CALIFORNIA MEDICAL ASSOCIATION

In compliance with the Constitution and By-Laws and with the resolution of the House of Delegates, the following report of the Committee on Codification of the Constitution and By-Laws is published. The second notice required by the Constitution will be published later in the year.

It is recommended that members read this proposed codification in connection with the existing Constitution and By-Laws and make any desired suggestions to the Secretary for transmission to the Council.

CONSTITUTION

ARTICLE I
Name and Object

Section 1. The name of this Association shall be the "California Medical Association."

Sec. 2. The purpose of this Association shall be to federate and bring into one compact organization the entire medical profession of California, and to unite with similar societies of other states to form the American Medical Association and such regional associations as the House of Delegates may deem advisable; to extend medical knowledge and advance medical science; to elevate the standard of medical education and practice, and to secure the enactment and enforcement of just medical laws; to promote friendly intercourse among physicians; to guard and foster the interests of its members and to protect them against imposition; and to enlighten and direct public opinion in regard to the great problems of medicine and public health, so that the profession may become more capable and honorary within itself, and more useful to the public, in the prevention and cure of disease, and in the prolonging and adding comfort to life. This Association as a constituent unit of the American Medical Association hereby recognizes and pledges its support to the Constitution and By-Laws of the American Medical Association and rulings by competent authority thereof.

ARTICLE II
Component Societies

Component societies shall consist of those county, district and other constituent societies which hold charters from this Association and whose Constitution and By-Laws, rulings, activities and procedure are not in conflict with the Constitution and By-Laws and decisions of competent authority of this Association.

ARTICLE III
Members

Section 1. Members—The members of the Association shall be the members of the component district, county and other constituent medical societies and associate members of this Association as provided in Section 2 hereof.

Sec. 2. Associate Members—Associate members shall be elected from those persons who by education, training and experience in sciences so closely allied to medicine as to make their affiliation with this Association desirable in the opinion of the Council. They shall be elected by the Council. Associate members shall pay such annual dues and enjoy such rights and privileges as the Council shall from time to time prescribe.

Sec. 3. Inactive Members—Inactive members shall be elected from those doctors of medicine eligible for active membership, but who are for any reason satisfactory to the Council of the constitutent society and the Council of the State Association, entitled to special consideration. These members shall have all the rights and privileges of other members, except medical defense, and shall pay nominal dues of one dollar a year to the constituent society and one dollar a year to the State Association.

Sec. 4. Persons eligible for membership and inactive membership under the provisions of this Constitution are not eligible for any other type of membership either in the constitutent or State society. Honorary membership is limited to and in addition to active or inactive membership in State and constituent societies.

Sec. 5. Guests—Any person may become a guest during any annual meeting, on invitation extended by the Secretary with the approval of the Council or the Executive Committee. Guests shall be accorded the privilege of participating in all of the scientific work for that meeting.

ARTICLE IV
House of Delegates

The House of Delegates shall be the legislative body of the Association, and shall consist of (1) Delegates elected by the county, district and other component societies, (2) the Councilors, and (3) ex-officio, the President, President-elect, Vice-President and Secretary of this Association.

ARTICLE V
Meetings

Section 1. The regular meetings of this Association shall he held annually at such times and place as the Council shall fix; and notice thereof shall be published in the Journal of this Association in at least two regular issues preceding such regular meeting.

Sec. 2. Special meetings of the House of Delegates may be convened as the By-Laws provide. Twenty-five members shall constitute a quorum in the House of Delegates.

ARTICLE VI
Officers

Section 1. The officers of this Association shall be a President, a President-elect, a Vice-President, a Secretary, and fifteen Councilors, of whom one shall he elected from each of the nine Councilor districts and six at large, two of whom shall be elected from the County of Los Angeles, and four from the remainder of the State. Not more than three Councilors shall be elected from any one Councilor district. These officers shall be elected by the House of Delegates at the time and in the manner provided in this Constitution and the By-Laws.

Sec. 2. The officers, except the Councilors, shall be elected annually. The terms of the elected Councilors shall be for three years.

Sec. 3. The Association shall elect a President for the next succeeding year who shall remain President elect for one year preceding his assumption of the office of President. While President-elect he shall be ex-officio a member of the Council and of all other bodies and committees of which the President is an ex-officio member.

Sec. 4. No delegate shall be eligihle to any office named in the preceding section, except that of Councilor, and no person shall be elected to any such office who has not been a member of the Association for two years next preceding his election.

ARTICLE VII
Council

The Council shall consist of the elected Councilors and the President, the President-elect, the Vice-President and the Secretary, ex-officio. Besides its duties mentioned in the By-Laws, it shall constitute the Finance Committee of the House of Delegates. Five Councilors shall constitute a quorum.

ARTICLE VIII
Section and District Societies

The Council shall provide for a division of the work of the Association into appropriate sections, and shall assist in the organization of such district societies as will promote the best interests of the profession, such societies to be composed exclusively of members of component county or other constituent district societies.

ARTICLE IX
Funds and Expenses

Funds shall be raised by equal per capita assessments upon the active members of each component society. The amount of assessments shall be fixed by the House of Delegates by a two-thirds vote thereof of those present. The fiscal year of the society shall he from January 1 to December 31. The number of members in good standing in each component society on the first day of March of each year shall be taken as the basis for the assessment for that fiscal year.

ARTICLE X
Referendum

The House of Delegates, in regular or special session assembled, or the Council, may by a two-thirds vote submit any question in such form as either of said bodies approve, to all of the members of the Association by mail, and a majority of the vote so cast by mail by the members of this Association shall bind the Association and all constituent societies thereof upon the question presented.

ARTICLE XI
The Seal

The Association shall have a common seal, with such inscription thereon as the Council shall prescribe.

ARTICLE XII
Amendments

The House of Delegates may amend any article of this Constitution hy a two-thirds vote of the delegates present at any annual meeting, provided that such amendment shall have been presented in open meeting at the previous annual meeting, and that it shall have been published twice during the year in the Journal of this Association, or sent officially to each component society for at least two months before the meeting at which final action is to be taken.

BY-LAWS

ARTICLE I
Membership

Section 1. All members of county and other constituent societies, except associate or honorary members, shall by virtue of such membership, be members of this Associaton upon certification by the Secretary of the component society of such membership and the receipt of the assessment for the fiscal year.

Sec. 2. Any person who is under sentence of suspension or expulsion from a component society, or whose name has been dropped from its roll of members, shall not be entitled to any of the rights or benefits of this Association, nor shall he be permitted to take part in any of its proceedings, nor receive its publications, until he has been relieved of such disability.

Sec. 3. It shall be the duty of the Secretary of each component society to furnish the Secretary of this Association before the first day of March of each year a list by names and addresses of all members in good standing on the first day of January of each year, and

to notify the State Secretary monthly of all changes in membership of the constitutent society, with corresponding change of address.

Sec. 4. Any physician residing in a county in which there is no county or other constituent society may make application for membership to the county or other constituent society nearest to the county in which he resides, or which he can most conveniently attend.

ARTICLE II
Meetings

Section 1. The annual meeting of this Association shall be held at such time and place as the Council shall appoint.

Sec. 2. Special meetings of the House of Delegates may be called by the President upon request so to do by a majority vote of the Council, and shall be called by him upon the written request of at least twenty delegates, provided that each delegate is notified as to time, place and object of the proposed meeting, by written notice, given at least ten days prior thereto.

Sec. 3. General Sessions, Sessions of the House of Delegates and Section Meetings—the time for the convening of each thereof, the number of meetings, duration and place thereof, shall be fixed by the chairman of the committee on scientific program, with the approval of the Council.

Sec. 4. The Association in general session assembled may instruct the House of Delegates to appoint committees or instruct officers in any matter of special interest and importance to the profession and to the public.

ARTICLE III
House of Delegates

Section 1. The House of Delegates shall be the legislative body of the Association, and shall consist of the officers of the society and delegates representing each component society.

Sec. 2. Each component society shall be entitled to send to the House of Delegates each year one delegate and one corresponding alternate for every fifty members, and one for each major fraction thereof, provided that each component county or other constituent society which has made its annual report and paid its assessment, as provided in this Constitution and By-Laws, shall be entitled to one delegate and one alternate.

Sec. 3. Twenty-five delegates shall constitute a quorum.

Sec. 4. Delegates and alternates shall be elected for a term of two years, and those societies entitled to more than one representative shall arrange such election so that one-half of their delegates and alternates, as near as may be, shall be elected each year.

Sec. 5. The House of Delegates or the Council shall approve all memorials and resolutions of whatever character issued in the name of the Association before the same shall become effective.

Sec. 6. The sessions of the House of Delegates shall be open to all members of the Association.

Sec. 7. The House of Delegates shall have authority to appoint committees for special purposes from among members of the Association who are not members of it. Such committees shall report to the House of Delegates, and may be present and participate in the debate on their reports.

Sec. 8. The House of Delegates shall elect representatives to the House of Delegates of the American Medical Association in accordance with the Constitution and By-Laws of that body.

ARTICLE IV
Duties of Officers

Section 1. The President shall preside at the meetings of the Association and of the House of Delegates; he shall appoint all committees not otherwise provided for; and perform such other duties as custom and parliamentary usage may require.

Sec. 2. The Vice-President shall assist the President in the discharge of his duties and act for him in his absence.

Sec. 3. The Secretary shall attend the general meetings of the Association; the meetings of the House of Delegates and of the Council, and shall keep the minutes of their respective proceedings. He shall be ex-officio Secretary of the Council. He shall be custodian of all records, books and papers belonging to the Association, and shall keep account of and promptly turn over to the depositary all funds of the Association which come into his hands. He shall provide for the registration of the members and delegates at the annual meetings. He shall, with the co-operation of the secretaries of the component societies, keep an approved register of all the members of the Association by counties, noting on each his status in relation to his county or other constitutent society. He shall aid the Councilors in the organization and improvement of the county and other constituent societies and in the extension of the usefulness of this Association. He shall conduct the official correspondence, notifying members of meeting, officers of their election, and committees of their appointment and duties. He shall employ such assistants as may be ordered by the Council, and shall make an annual report to the House of Delegates. He shall supply each component society with the necessary blanks for making its annual report; he shall keep an account with the component societies, charging against each society its assessment, collect the same and promptly turn it over to the depositary. He shall in like manner keep an account with each member as to any assessment or assessments levied directly upon each member, collect the same and promptly turn it over to the depositary. As chairman of the committee on scientific program, he shall prepare and issue all programs. He shall perform such other duties as the Council shall direct. The amount of his salary shall be fixed by the Council.

Sec. 4. The depositary of the Association shall be a bank or trust company to be selected by the Council. All funds received for the Association by any officer or agent thereof shall be promptly deposited with the depositary. The depositary shall pay out the money of the Association only upon a check or draft signed by the Secretary and countersigned by the chairman or other designated member of the Council. The Secretary shall issue such checks or drafts only upon vouchers approved by the Auditing Committee and signed by all the members thereof. A revolving fund in such amount as may from time to time be fixed by the Council shall be left with the Secretary, from which fund immediate cash demands shall be paid.

ARTICLE V
Council

Section 1. The Council shall meet on the day preceding the annual meeting and daily during its sessions, and it shall also hold at least three other meetings during the year, at least one of which shall be held in the southern part of the State. Special meetings may be called by the chairman at any time, and he shall call a special meeting upon the written request of at least three councilors, provided written notice for not less than three days of the time, place and object of the proposed special meeting be given by the secretary. At the meeting held on the last day of the annual meeting of the Association the Council shall reorganize and shall elect a chairman for the ensuing year. Its chairman shall make an annual report to the House of Delegates of its proceedings.

Sec. 2. The Council shall have power to invest the funds of the Association, and to do and perform all acts and transact all business for and on behalf of the Association when the House of Delegates is not in session. It shall also have power to delegate such powers and duties as it may determine to the Executive Committee hereinafter provided for.

Sec. 3. In the event of a vacancy in the Council, or in the office of the Secretary, or in any elective or other office not otherwise provided for, the Council shall fill the vacancy until the next annual election or other regular selection, as provided for in the Constitution and By-Laws.

Sec. 4. The Council shall provide for the publication and distribution of a periodical to be known as the "Journal of the California Medical Association," or some similar title to be determined by the Council, and such other publications as may be necessary, and shall have authority to employ at such salary as it may deem proper, an editor, who shall be responsible to the Council, and who shall properly edit and conduct the offcial journal and such other publications as may be authorized by the House of Delegates or the Council.

Sec. 5. The Council shall secure the services of competent public accountants and cause them to audit the accounts of all officers, committees and agents of the Association at least once a year, and shall present such report to the House of Delegates.

Sec. 6. The Council shall divide the State into Councilor districts, according to the number of districts fixed by Article VI, Secton 1, of the Constitution, specifying what counties each district shall include. Whenever the number of delegates, as provided in Article III, Section 2, exceeds one hundred, it shall make a reapportionment that shall bring the number of delegates within this limit, after carefully examining the membership list of component societies to determine therefrom the number of delegates in excess of the one delegate to which each county or other constituent society shall be entitled. Such reapportionment shall take place at the annual meeting next succeeding that at which the reapportionment is approved by the House of Delegates.

Sec. 7. The Council shall, upon application, issue charters to county or other constituent societies organized to conform to the letter and spirit of the Constitution and By-Laws, rulings and regulations of this society, and such county or other constituent society shall not amend or change the same, contrary thereto. The Council shall, upon application, issue similar charters to other societies of physicians, otherwise qualified to become members of a county society and of this Association, where by reason of geographical or other conditions county organizations are not feasible or calculated to promote the best interests of the profession or of the public. Said district or constituent societies shall in like manner be organized to conform to the letter and spirit of the Constitution and By-Laws, rulings and regulations of this society, and such constituent societies shall not change or amend the same contrary thereto.

Sec. 8. The Council, when the best interest of the Association and profession will be promoted thereby, shall organize district medical societies, and all members of the component county societies, and no others, shall be members in such district societies.

Sec. 9. The Council may promote and cause to be organized societies of medical or premedical students in any approved teaching institution in this State, with such affiliation with this Association and under such control as it shall deem advisable and proper.

Sec. 10. The Secretary, with the written authoriza-

tion of the chairman, may submit any urgent question to the Council by mail ballot.

Sec. 11. The chairman shall annually appoint a committee of two who shall audit the accounts of the Association at least once every month, and who shall have general supervision of all the finances of the Association. Said Auditing Committee shall elect a chairman.

Sec. 12. The Council shall appoint an attorney-at-law in good standing, practicing his profession at San Francisco, to act as general attorney for the Association, and an assistant general attorney practicing his profession at Los Angeles to act as assistant general attorney. The general attorney shall, so far as possible, attend the sessions of the Council and of the House of Delegates and shall generally advise and counsel with the councilors and officers of the Association. The general attorney and assistant general attorney shall have charge of all actions for malpractice against individual members of the Association on behalf of such members whenever their defense is authorized by the Associaton, through the Council, the Executive Committee or the Secretary thereof.

Sec. 13. In all matters not otherwise provided for in this Constitution and By-Laws, the Council shall be the judicial, legislative and policy-making body of this Association. All questions of more than local importance whether involving interpretation of ethics, definition of policy, decision in controversy, financial, organizational or other matter not provided for by this Constitution and By-Laws shall be referred to the Council for action, and this action shall be binding upon the Association and its constituent member societies, provided that the action by the Council is subject to review by the House of Delegates or by the general referendum.

Sec. 14. The Executive Committee shall consist of the President, the President-elect, the Vice-President of the Association, the chairman of the Council, the chairman of the Auditing Committee, the Secretary, the editor and the general attorney. The committee shall elect its own chairman, and the Secretary shall act as secretary thereof. It shall keep a record of its proceedings and report them to the Council. It shall initiate action, investigate or take charge of all matters in which the welfare and the best interests of the public and the Association are mutually concerned. It shall act in the place of the Council when the later is not in session, all of its steps and proceedings, however, to be subject to the approval of the Council.

ARTICLE VI

Order of Procedure

The Program Committee shall consist of the Secretary of the Association and four members of the Association who shall be elected by the House of Delegates, one each year to serve for four years. The Secretary of the Association shall he the chairman thereof. It shall determine the character and scope of the scientific proceedings of the Association, subject to the instructions of the Council, and shall provide for and fix the order of business at the sessions of the general meeting, the sessions of the House of Delegates and the sessions of each section.

ARTICLE VII

County Societies

Section 1. Each county and other constituent society of this Association, which has adopted principles of organizaiton not in conflict with the Constitution and By-Laws, rulings and procedures of this Association, shall, on applicaton, receive a charter from and become a component part of this Association. Such charters shall provide that the Constitution and By-Laws and procedures of the constituent member society shall not be amended in any way which might conflict with the Constitution and By-Laws of the American Medical Association and of this Association as originally drawn or as modified by competent authority, except by and with the written approval of the Council of this Association.

Sec. 2. Charters shall be issued only upon approval of the Council or House of Delegates, and shall be signed by the President and Secretary of this Association. The Council or the House of Delegates shall have authority to revoke the charter of any county or other constituent society whose actions are in conflict with the letter or spirit of the Constitution and By-Laws, policies and procedures of this Association.

Sec. 3. Only one component medical society shall be chartered in any one county, provided that the physicians in a portion of any one county who can show adequate reasons satisfactory to the Council therefor may be authorized to join a constituent district society as elsewhere provided for in this Constitution and By-Laws.

Sec. 4. Each county or other constituent society shall judge the qualifications of its own members. However, as such societies are integral parts of this Association and the basis of membership in the American Medical Association, it is necessary that the qualifications meet the minimum requirements of the State and national organizations. These minimum requirements are that to be eligible for election as an active or inactive member the applicant must hold the degree of doctor of medicine from an accredited medical school for active membership and must be licensed to practice medicine and surgery in the State of California. He must not practice or claim to practice or lend his support, co-operation or in any other way endorse any exclusive system of medicine or any person practicing the same. He shall be honorable and ethical in his conduct and shall subscribe to the principles of medical ethics of the American Medical Association, and shall recognize the Council of this Associaton as the proper authority to interpret any doubtful points about ethics. Every applicant for membership in a component society shall fill out and sign in duplicate the application blanks provided by the Society which prescribe the necessary qualifications for membership. One copy of each such application shall be promptly forwarded to the office of the State Secretary.

Sec. 5. Any physician who may feel aggrieved by the action of the society of his county in refusing him membership, or in suspending or expelling him, shall have the right to appeal to the Council within three months, and if the decision of the Council be questioned, an appeal may be taken to the House of Delegates, whose decision in any case shall be final.

Sec. 6. In hearing appeals the Council may admit oral or written evidence as in its judgment will best and most fairly present the facts, but in case of every appeal, both as a board and as individual councilors in district and county work, efforts at conciliation and compromise shall precede all such hearings.

Sec. 7. When a member in good standing in a component society moves to another county or other jurisdiction in this State, his name, on request, shall be transferred, without cost, but upon assuming such financial obligation as shall be deemed proper by the component society to which transferred.

Sec. 8. A physician living on or near a county line may hold his membership in that county most convenient for him to attend, provided that the consent of the society of the county in which such physician may reside be first obtained, and also the consent of the society which he desires to join.

Sec. 9. The Secretary of each component society shall keep a roster of its members and of the non-affiliated registered physicians of the county, on which shall be shown the full name, address, school and date of graduation, date of license to practice in this State, and such other information as may be deemed necessary. In keeping such roster the Secretary shall note and at once notify the State Secretary of any changes in the personnel of the profession, by death or by removal to or from the county, and in making his annual report he shall be certain to account for every physician who has lived in the county during the year. The Secretary of each component society shall make a monthly report to the Secretary of the Association upon forms and including such subjects as the Council shall authorize.

Sec. 10. The Secretary of each component society shall forwarded its assessments, together with its roster of officers and members, list of delegates and alternates and list of non-affiliated physicians of the county to the Secretary of this Association before the first day of March of each year. Only those delegates and alternates who are duly elected and certified to the State Secretary before March 1 shall have the right to represent their society in the House of Delegates.

Sec. 11. Any county society which fails to pay its assessment or make the report required on or before March 1 shall be held as suspended, and none of its members, delegates or alternates shall be permitted to participate in anv of the business or proceedings of the Association or of the House of Delegates during the annual session of that year, nor thereafter, until all requirements for membersip have been met.

Sec. 12. No member of a component society shall be deprived of his membership unless by his own act, except by a three-fourths affirmative vote of all the members present at a regular meeting, and after an opportunity has been given for the accused to be heard in his own defense; but a member shall be dropped on the revocation of his certificate by the Board of Medical Examiners of California.

Sec. 13. When a member shall resign his membership in a component society, he shall thereby forfeit all right and title to any share in the privileges and property of the California Medical Association.

Sec. 14. Any county or other constituent society may, in its discretion, create associate members from persons engaged professionally in branches of science allied to medicine but not holding the degree of doctor of medicine. Associate and honorary members of any county or other constituent society are not members of this Association. However, when the constituent society follows the provisions of the State Association in its inactive and associate membership provisions, such associate or inactive members of constituent societies may be elected to corresponding position in the State Association membership by the Council.

ARTICLE VIII

Miscellaneous

Section 1. The principles of medical ethics of the American Medical Association are adopted as the ethics of this Association and are made part of the charter provisions for constituent societies. Interpretation of points in ethics about which there may be any controversy shall be submitted to the Council of the State Association for ruling, and this ruling shall be final and authoritative, provided the House of Delegates by vote may ratify the action of the Council.

Sec. 2. New members who join a component society

after July 1 shall pay only one-half the regular annual assessment for such fiscal year.

Sec. 3. The deliberations of this Association shall be governed by parliamentary usage as contained in Robert's Rules of Order, when not in conflict with this Constitution and By-Laws.

ARTICLE IX

Amendment to By-Laws

Section 1. The House of Delegates is authorized to amend any article or section of the By-Laws by a three-fourths affirmative vote of the delegates present; provided, that such amendment has been submitted in writing and laid on the table for twenty-four hours previous to being voted upon.

Sec. 2. The Constitution and By-Laws heretofore governing this Association are hereby repealed, and this Constitution and By-Laws shall be in full force and effect immediately after it is declared duly adopted.

An Efficient and Inexpensive Device for Cutting Bandage Rolls—The Travers Surgical Company have perfected a simple device which enables one to cut bandages any desired size with edges clean and even. As a time saver it is of much value. There are no threads clinging to the bandages. This device is very compact and portable, as it weighs but a few pounds. The use of this bandage cutter eliminates the necessity of carrying a large stock of bandages of assorted sizes, thereby creating a big saving, as the difference in cost of the yard bandage roll and ready-cut bandages is considerable. The many advantages of the Klean Edge Bandage Cutter can be readily seen.

Troy Laundry Machinery Company Move Their Factories—The Troy Laundry Machinery Factories have been moved from Chicago to East Moline, Ill. All of the manufacturing departments of this great company are now in operation in one center. The factories cover eighty-three acres consisting of fourteen buildings grouped around an administration building and a factory office. Hospitals interested in laundry machinery make no mistake with dealing with the Troy Laundry Machinery Company.

COUNTY NEWS

ALAMEDA COUNTY

Alameda County Medical Society (reported by C. L. McVey, secretary)—The Society met on August 21; E. E. Brinckerhoff, president; C. L. McVey, secretary. The scientific program consisted in a discussion of brain injuries. Howard Naffziger of San Francisco presented the subject as (a) clinical classification of brain injuries according to pathological findings; (b) description of a new group of cases amenable to surgical treatment; (c) the interpretation of pressure signs and the indications for surgical treatment. O. D. Hamlin, J. H. Buteau, C. A. Dukes and M. L. Emerson took part in the discussion. The revised constitution and by-laws were adopted.

BUTTE COUNTY

Enloe Hospital Temporarily Closed—It is reported that the three head nurses of Enloe Hospital left the institution suddenly. As a result of this action, it has been necessary to close the hospital for all but emergency work for a period of ten days or two weeks. The physicians of the community are co-operating to keep the hospital operating until a new staff of nurses can be secured. The nurses who resigned are: Miss Margaret Brown, Miss Adalaine Wildman and Miss Marie Joachims.

GLENN COUNTY

Willows Sanitarium—This hospital, owned by Etta Lund, M. D., has just issued an annual report. During the year 105 operations were performed and a large number of all classes of medical cases were treated. The hospital is equipped with Brahamhall-Deane sterilizer and has other facilities for doing safe work.

KERN COUNTY

Alice Cooper Memorial Hospital—Mr. Chester Conklin is constructing a sanitarium, particularly for patients suffering from tuberculosis, on his four hundred acre ranch located in the Horseshoe Valley of the Mojave Desert about one hundred miles from Los Angeles. Mr. Conklin is spending a considerable amount of money to make this sanitarium attractive and has secured the services of Doctor John T. Bernard as medical director.

LOS ANGELES COUNTY

William Day Moore, M. D., Health Officer of San Pedro, has resigned in order to give his entire time to his private practice.

MARIN COUNTY

Marin County Medical Society (reported by C. A. DeLancey, secretary)—The Society held a business meeting on the last Thursday of July, the principal subject being the Fee Schedule as adopted by the Council.

Dr. C. A. DeLancey has resigned from the State Prison at San Quentin, where he has held the position of assistant physician, in order to go into private practice in San Anselmo. Dr. Northrop succeeds Dr. DeLancey at the prison.

Presbyterian Orphanage at San Anselmo—The Presbyterian Orphanage at San Anselmo, which was burned to the ground several months ago, is being rapidly reorganized. The new organization will consist of cottage units. Dr. Blatry, the superintendent, expects that three of these cottages will be ready for occupancy before December. Medical attention is rendered gratis by the physicians of the County.

SAN DIEGO COUNTY

Meeting of Council of San Diego County Medical Society (reported by Geo. B. Worthington, secretary)—Applications of Drs. Chas. E. Howard and W. A. Alton for membership by transfer were considered by the council, and on motion these applicants were elected to membership.

The industrial medicine blanks received from thirty-two physicians were presented to the Council for approval. On motion the secretary was instructed to forward the completed blanks to the State secretary with a clause relative to the Society's opinion as to individual competency in the different lines of work unsigned, and further instructed the secretary to notify the State secretary that while the Society felt competent to certify as to the individual's standing and membership in the County unit, it considered it impracticable to definitely certify as to competence in any indicated subject.—Bulletin of San Diego County Medical Society, July 21, 1922.

Early Days of the San Diego County Medical Society—There seems to be evidence that an attempt was made in 1880 and again in 1886 to start a San Diego County Medical Society, but both seem to have run a short course owing to jealousies existing among the physicians of those days. The present County Medical Society was started at a meeting held early in 1887.—Fred and Charlotte Baker, in the Bulletin of the San Diego County Medical Society, July 21, 1922.

Elwyn Sanitarium—W. D. Rolph, M. D., has associated himself with Dr. E. S. Coburn of National City in the conduct of the Elwyn Sanitarium, which will continue to be operated as an open staff general hospital.—The Bulletin, San Diego County Medical Society, July 21, 1922.

SAN FRANCISCO COUNTY

New Director Bureau of Hygiene, California Board of Health—Dr. Ellen S. Stadmuller of this city has been appointed director of the State Bureau of Hygiene to fill the vacancy left by the resignation of Dr. Ethel M. Watters. Dr. Stadmuller is a graduate of the University of California Medical School, and has practiced medicine in San Francisco since 1912. The State Board of Health, coincident with accepting the resignation of Dr. Watters, accepted also that of Miss Mary K. Clary, a public health nurse. The action of the board was taken at the conclusion of a probe into alleged irregularities in the filing of expense claims by the two women, whose dismissal was recommended by the State Board of Control several weeks ago.—S. F. Examiner, July 3, 1922.

Medical Social Workers—The California Association of Medical Social Workers met at "tea" at one of the hotels August 4. Dr. Richard Cabot of Boston led a discussion on case work and case records—the social service exchange and pay clinics.

Academy of Medicine—The Academy of Medicine met at dinner on August 26, and was addressed by Richard Cabot, M. D., of Boston.

SAN MATEO COUNTY

Alexander Sanitarium—The Alexander Sanitarium, for the care of patients suffering from nervous and mental disorders, has recently completed a new and modern physiotherapy department at a cost of $18,000. This sanitarium, located twenty-two miles south of San Francisco, in the foothills near Belmont, California, and near the California Tuberculosis Sanitarium, accepts patients of any licensed physician and surgeon.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by A. C. Soper, secretary)—The July meeting was held in the Cottage Hospital on July 10 with thirteen members and three guests present. Walter M. Dickie, M. D., secretary of the State Board of Health, presented a paper with graphic charts showing mortality and morbidity rates of the State with particular reference to contagious diseases dating from 1906, when the first fairly accurate records began to be made. Discussion was entered into by members present. Lloyd Mills, M. D., of Los Angeles, read a paper on "Modern Cataract Surgery," discussed by G. W. Jean and L. R. [illegible]. Jesse P. Truax, of Lompoc, was elected to membership. The secretary reported correspondence with Drs. Dickie and Mills, Edwin I. Bartlett, and the League for the Conservation of Public Health. Application cards to the League were signed by H. F. Pierce, O. C. Jones, and G. W. Jean. Censors were reminded that it will be their duty to pass on the questionnaires for industrial medicine practice.

Santa Maria Hospital Plans Progressing—It is reported that earnest work is being carried forward looking to the building and maintenance of a hospital in Santa Maria. Among those interested in this important problem are: Dr. Coblenz, Dr. Brown, Mrs. H. E. Easton, Mrs. George Scott, E. D. Rubel, A. McNeill, L. P. Scaroni.

Improvements in Orcutt Hospital—It is reported that Dr. C. D. Dickey has provided extensive improvements in the Orcutt Hospital. It is reported that this hospital is owned by Drs. French and Early, of Los Angeles.

SANTA CLARA COUNTY

Santa Clara Medical Society (reported by E. P. Cook, secretary)—The regular meeting of the Society was held July 19, 1922, at the Oaks Sanitarium, Los Gatos, with an attendance of twenty-five members. Robert P. Gober and Paul C. Alexander were elected to membership. The scientific meeting was conducted by Dr. Voorsanger, who discussed recent advances in the treatment of tuberculosis. Heliotherapy and the method of performing artificial pneumothorax were demonstrated. C. M. Richards read a paper on the X-ray diagnosis of pulmonary tuberculosis, stressing the importance of the Roentgenologist as a medical consultant. Appreciation was voiced of Doctor Voorsanger's hospitality. Refreshments were served after the adjournment of the meeting.

STANISLAUS COUNTY

Oakdale Hospital Bond Issue Fails to Carry—The proposition to vote $35,000 for bonds to erect a municipal hospital in Oakdale was defeated by a vote of 141 to 76.

TUOLUMNE COUNTY

Tuolumne County Medical Society (reported by W. L. Hood, secretary)—The May meeting of the Tuolumne County Medical Society was a public meeting held in the opera house. Dr. Hirshfelder of Belmont Sanitarium addressed the meeting. The important public health problem of "campers along the streams" in Tuolumne County was considered by the Society. The Society went on record as being in favor of more and better paid health officers.

Hospital Facilities of Tuolumne County—Hospital facilities for the people of Tuolumne County are: County Hospital at Sonora, sixty beds for male patients and twenty for females; Bromley Sanitarium at Sonora, private sanitarium of ten beds, owned by R. I. Bromley, M. D., and open to all physicians; Sierra Hospital, twenty-four beds, owned by E. T. Gould, M. D., at Sonora; Tuolumne Hospital, fifteen beds, owned by E. H. Reid, and located at Tuolumne.

Hetch-Hetchy Hospital Destroyed by Fire—The hospital used for the care of employes on the Hetch-Hetchy water supply proposition for San Francisco was destroyed by fire recently. There were twenty-nine patients in the hospital at the time, and only by heroic work were their lives saved. Nurse Ethel Moyer lost her life as a result of burns received while moving patients from the

hospital. After removing the last patient, Mrs. Moyer, with her clothing afire, jumped from the second story of the hospital and suffered a broken back. A movement is under way to commemorate the sacrifice made by Mrs. Moyer by the erection of the Ethel Moyer Memorial Hospital on the ground previously occupied by the hospital that was burned.

YOLO COUNTY

Yolo County Medical Society (reported by Lela J. Beebe, secretary)—The quarterly meeting of the Society was held in the County Court House, Woodland, June 20. Present: Bates, Beebe, Blevins, F. R. Fairchild, King, Keith, Lawhead, Lawson, Newton, and Ward. Absent: Craig, Desrosier, C. H. Fairchild, Goffin, McManus, Parsons, and Poage. H. D. Lawhead made a delegate's report on the 1922 State Medical Society meeting. Charles Keith presented a paper on the diagnosis and medical aspects of cholecystitis. F. R. Fairchild discussed the diagnosis and surgical aspects of cholecystitis. The papers were followed by a general discussion participated in by all members present. The secretary was instructed to write to President-elect Thomas Clay Edwards, a former Yolo County man, conveying to him the congratulations of this society on the signal honor conferred upon him.

The Higher Education of Chiropractors—What is your favorite light literature? Detective stories? Mystery stories? Humor? Have you ever read the publications issued by the various species and subspecies of the chiropractic cult—for there is, as you know, a lack of unanimity among the chiropractors. One particularly choice piece of contemporary journalism is issued by a chiropractor factory in Fort Wayne, Indiana. Its July (1922) issue makes good hot weather reading. The editor discusses a "model bill," recently drawn up by those chiropractors of Indiana who belong to a different subspecies from those represented by the publication in question. This Fort Wayne journal views the bill with disfavor. It says, with refreshing naivete:

"To begin with there is absolutely no need of a chiropractic licensing and examining board in Indiana today. The existing lot of chiropractors in Iniana cannot be improved upon. You are not being persecuted or prosecuted, you are left severely and strictly alone to practice your profession without any let or hindrance from any source or any group of any kind. In fact, Indiana today is the best chiropractic state in the entire country. Chiropractic conditions are as near ideal as it is humanly possible to approach that condition."

But the fact that Indiana is the home of the free, chiropractically speaking, is not the only objection this journal has to the proposed bill. It seems that the bill would require applicants for chiropractic examinations to submit satisfactory proof of the possession of a preliminary education, equal to that of a high school. Perish the thought! As the editor says:

"How many chiropractors in Indiana today could qualify under that rule? Of all the chiropractors in Fort Wayne, I do not happen to know one that is a high school graduate. In fact, I believe that the total number in Indiana able to comply with that ruling would be less than two per cent of all the chiropractors in the state."

From the point of view of the owner of a chiropractic "college" the sentiments just quoted are eminently logical. It would be entirely unfair to chiropractic schools to insist on matriculants being educated human beings. What educated human being would ever attend a chiropractic school? Of course, from the point of view of public interest—but that's another story.—Journal of A. M. A., July 15, 1922.

BUSINESS AND THE BUSY PHYSICIAN

Why not let our advertisers help you?

Banking and Investments—It is one thing to have a large gross income. It is quite another matter to convert a large percentage of this income into net profits. The most difficult of all business ventures is to make money make money within the bounds of reasonable safety for the original investment.

The fixed charges or "overhead" expenses of physicians are, as a rule, higher in proportion to volume of income than for any other class of citizens. With social conditions as they are, the factors that produce this extra burden will continue operative and consequently the net earned dollars of physicians are small in proportion to their incomes. Realization of these conditions should make physicians conservative and particularly careful as to the safety of their earnings and (particularly careful as to) their investments.

In order to be of as much assistance as possible to our members in business, as well as in professional affairs, the executive committee approves the policy of advertising safe banking and investment houses who are willing to give advice to physicians by personal visit or by correspondence. In this issue will be found the advertisements of three banks and trust companies. They are:

Union Trust Company, Market street and Grant avenue, San Francisco.

The San Francisco Savings and Loan Society, 526 California street, San Francisco.

Anglo-California Trust Company, Market and Sansome streets, San Francisco, with branches at Market, McAllister and Jones, Mission and Sixteenth, Fillmore and Geary, 101 Market, Third and Twentieth, and branch offices of the bond department at 210 Syndicate Bldg., Oakland, and 1112 Pacific Mutual Bldg., Los Angeles.

These are all reliable, conservative institutions which are ready not only to protect your funds but to give you in a personal, confidential way the expert advice regarding investments that they would expect you to give them regarding health.

A Relief From Office Worries—A fortunate few physicians have so complete an office organization as to enjoy relief from the annoying, yet nevertheless important, details of the business side of practice. However, to the greater number this is a problem.

Realizing the difficulty the majority are confronted with in this regard, two local business women, Gail Sheridan and Mary Downing, have organized a complete visiting secretarial and accounting service, whereby small offices as well as large ones may be maintained in a thorough, modern and efficient manner.

The bane of many a physician's existence is the collection of his accounts, and the service offered by Miss Sheridan and Miss Downing embraces a tactful and systematic method for the collection of accounts. In addition, the service embraces the skillful handling of correspondence and accounting, installation of accounting systems, keeping of checking accounts and bank balances in order, and the preparation of income tax returns.

The many years' experience of Miss Sheridan and Miss Downing in important executive and secretarial positions in San Francisco office organizations specially equip them for the handling of business requiring confidence and trust. Their program and credentials have had serious consideration by the officers of the Medical Society. Their announcement appears on page 42 of the

advertising section, and their plans and methods have the endorsement of the Journal.

Gas and Oxygen—Hospitals and physicians are interested in gas and oxygen exactly as they are interested in drugs, instruments or any other substance in the practice of medicine and public health. Legitimate interest concerns itself in any of these products essentially in quality, price, adequacy of supply and the ethics of marketing.

There are several sources of gas and oxygen in California. There are also several prices, some variation in qualities and quite a variation in the ethics of marketing.

The Journal with this issue carries an advertisement of the Western Nitrous Oxide Company, one of the latest firms to enter the market in California. As in all other advertisements, the Journal has considered carefully for several months the methods and policies of this company before accepting their advertisement. They have complied with all the requirements made by the State Society, and their copy appears in this issue.

Comments regarding the product of this company, as well as upon the general question of the supply of anesthetics for hospitals, will be welcomed by the Council of the Medical Society.

PACIFIC COAST ASSOCIATION OF ANESTHETISTS

Joint Session With the Section on Anesthesiology of the California State Medical Society, Yosemite Valley, May 15-16, 1922

Minutes First Scientific Session

George P. Waller, President of the Pacific Coast Association of Anesthetists, called the meeting to order for the first scientific program, May 16, in the Hotel Sentinel, Yosemite village.

After preliminary announcements by the chair concerning transportation and entertainment, F. H. McMechan, Honorary Secretary of the Pacific Coast and Secretary of the American Association of Anesthetists, was introduced as the guest of the Association and recognized leader among anesthetists. In a few well chosen words Dr. McMechan expressed his pleasure at being present and commended the progress made by the organization in so short a time. In token of his appreciation and as a memento from Mrs. McMechan and himself, he presented to the Association, through Eleanor Seymour and George P. Waller, a beautiful silver mounted gavel engraved with the names of the first president and secretary, to which succeeding ones shall be added. After acknowledging the gift of the general secretary the following program was presented:

1. Spasticity from Inflammation in Relation to Anesthesia. (President's address.) Dr. George P. Waller, Los Angeles. Discussed by Doctors Botsford, Palmer and Wilson.

2. Anesthesia and Its Relation to the Patient, from a Surgeon's Standpoint; Type of Anesthesia in Relation to Existing Pathology; Emoluments to the Anesthetist. Harlan Shoemaker, M. D., secretary Los Angeles County Medical Society. Discussed by Doctors Huggins, Botsford, Wilson, Seymour and McMechan.

3. Sacral Anesthesia—A New Method of Administration with Report of Use in Four Hundred Urologic and Gynecologic Cases. Albert J. Scholl, Jr., Mayo Clinic, Rochester, Minn. Discussion by Doctors Robert Day, Harlan Shoemaker, Mary Botsford and F. H. McMechan.

4. Suggestive Leads in Anesthesia. F. H. McMechan, M. D., secretary American Medical Editors' Association. Discussed by Doctors Waller and Crane.

Omitted because authors were detained Time as an Element of Safety in Anesthesia in Children. Mary T. Murphy, M. D., San Francisco.

The Heart in Surgery. E. E. Fisher, M. D., Salem, Oregon.

Executive Session.

After the completion of the scientific program, the president called the members to order for a brief business meeting.

A charter roll of sixty names was read and all having been duly passed upon by the executive board were unanimously elected to membership.

There followed the reading of the organization meeting during the session of the State Medical Society at Coronado Wednesday, May 12, 1921. Minutes adopted as read.

On behalf of the executive board the following resolutions were presented by the secretary and each adopted in turn:

Resolutions Adopted.

1. Be it resolved that the Pacific Coast Association of Anesthetists hereby extends its hearty appreciation of the splendid efforts of the State Board of Medical Examiners and their legal advisers in interesting themselves in protecting of the public health and welfare by limiting the administration of anesthetics to legally qualified physicians.

2. Be it resolved that the Pacific Coast Association of Anesthetists hereby extends its hearty appreciation of the splendid efforts of the League for the Conservation of Public Health, its officers and legal advisers in interesting themselves in the protecting of public health and welfare by limiting the administration of anesthetics to legally qualified physicians.

3. Whereas the safety of those coming to operation under anesthesia is a paramount issue in public health work, be it resolved that the Pacific Coast Association of Anesthetists hereby urges the Health Department of San Francisco to eliminate nursing anesthesia and the dangers attaching thereto, by introducing the administration of anesthetics by expert medical anesthetists in the San Francisco City and County Hospital and providing adequate funds for such purpose.

4. Resolved that Dr. F. H. McMechan be instructed to extend the greetings of the Pacific Coast Association of Anesthetists to the Canadian Association of Anesthetists at Winnipeg in June and to the joint meeting of the Interstate, Research and World's Congress in Columbus in October, 1922.

5. Resolved that Dr. Eleanor Seymour be instructed to extend the greetings of the Pacific Coast Association of Anesthetists to the joint meetings of the American Association of Anesthetists, Mid-Western, and the Anesthesia session of the American Medical Association in St. Louis the week of June 22, 1922.

6. Resolved that the Pacific Coast Association of Anesthetists, appreciating the influence of the International Congress of Medicine, on the advancement of anesthesia, hereby appoints Dr. Mary E. Botsford as official representative to the section on anesthesia, to convey its compliments and carry its scientific message to the London Meeting in 1923.

7. Whereas the protection of the patient be advancement of surgery and the development of hospital service demand the administration of anesthetics by qualified physicians, therefore be it resolved that the Pacific Coast Association of Anesthetists urges the American College of Surgeons through its members and hospital standardization to eliminate the nurse technician and to confine the administration of anesthetics exclusively to physicians.

The next order of business was the presentation

of the seal specially designed and artistically executed by Mrs. Neil C. Trew, wife of the incoming president of the Southern California Society of Anesthetists. After admiring inspection, the design was accepted and a rousing vote of thanks extended Mrs. Trew for her artistic creation. The motto suggested by Dr. McMechan, "Divinum est sedere dolorem"—"It is God-like to relieve pain," was also unanimously adopted.

Election of officers then followed and the ticket as proposed by the nomination committee was unanimously endorsed, as follows:

Officers Elected.

George P. Waller, M. D., Los Angeles, Cal., president; Mary E. Botsford, M. D., San Francisco, Cal., vice-president; Eleanor Seymour, M. D., Los Angeles, Cal., secretary-treasurer; Walter R. Crane, M. D., Los Angeles, Cal., executive board, 1924; David E. Hoag, M. D., Pueblo, Colo., executive board, 1924; M. J. Rand, Elko, Nev., executive board, 1925; Robert L. Charles, M. D., Denver, Colo., executive board, 1923; Caroline B. Palmer, M. D., San Francisco, Cal., executive board, 1925; Louise A. Oldenbourg, M. D., Oakland, Cal., executive board, 1923.

It was moved, seconded and carried that a cordial invitation be extended to the American Medical Association and its session on Anesthesia, and to the American Association of Anesthetists to hold a joint session with the Pacific Coast Association of Anesthetists in San Francisco in June, 1923. Adjourned.

Scientific Program Continued.

May 16

1. Ethyl Chloride as a General Anesthetic. Louise A. Oldenbourg, M. D., Oakland. Discussed by Doctors Walker, Botsford and Crane.

2. Physiological Effects of Nitrous Oxide. Neil C. Trew, M. D. Discussed by Doctors Botsford, Bunnell and Crane.

3. Symposium on Intratracheal Anesthesia. Mary Kavanagh, M. D., and Edith Williams, M. D. (The latter read by Dr. Botsford.) Demonstration of apparatus and general discussion.

Omitted.

Anesthol, a Most Useful Anesthetic Mixture. Louis H. Maxson, M. D., Seattle, Washington. (Unable to be present.)

Nitrous Oxide Anesthesia in Infants. Mary E. Botsford, M. D., San Francisco. (Points Previously covered in discussion.)

At the close of the program and before adjourning, Dr. McMechan exhibited photos of the cups to be presented to James T. Gwathmey and Isabella Herb for distinguished work in the specialty of anesthesia. Dr. McMechan also extended congratulations on the success of the initial P. C. meeting and pledged the co-operation of all the regional organizations.

Dr. Botsford then moved a vote of sincere thanks for the inspirational visit of Dr. McMechan, general secretary, and for his extensive contributions to anesthesia literature, as the efficient editor of several publications. Adjourned to June 26, 1923. Eleanor Seymour, M. D., secretary.

American Roentgen-Ray Society—The annual meeting of this national association will be held in Los Angeles, September 12 to 17, under the presidency of Albert Soiland.

Many members of our State Society and others will be in Pasadena for the Hospital Convention to be held at the Maryland Hotel, September 5, 6, 7 and 8. Why not plan to spend an additional week in Los Angeles and attend the meetings of the American Roentgen-Ray Society? There is no more delightful place anywhere than Southern California in September.

Write to Dr. Soiland, 1407 S. Hope street, Los Angeles, and you will receive a cordial invitation to the meeting.

Pharmacology and Therapeutics

Edited by FELIX LENGFELD, Ph. D.

Help the propaganda for reform by prescribing official preparations. The committees of the U. S. P. and N. F. are chosen from the very best therapeutists, pharmacologists, pharmacognosists and pharmacists. The formulae are carefully worked out and the products tested in scientifically equipped laboratories under the very best conditions. Is it not plausible to assume that these preparations are, at least, as good as those evolved with far inferior facilities by the mercenary nostrum maker who claims all the law will allow?

Evans Cancer Cure—Dr. R. D. Evans, of Brandon, Manitoba, sells a "positive cure for cancer." The price is "one hundred dollars in advance." The victim who parts with $100 for this cruel and worthless fake is told to shave a patch about the size of a silver dollar on the crown of the head. The "cure" is applied to this spot. This is for the treatment of internal cancer. "For 'external cancer' the discovery is applied on the spot." From an analysis made in the A. M. A. Chemical Laboratory, it was evident that Evans Cancer Cure is essentially a mixture of 1 part of a fatty substance (such as lard) and 5 parts of dried ferrous sulphate.—Journal A. M. A., June 3, 1922, p. 1739.

The Intravenous Use of Acacia—It is now generally accepted that acacia has a limited and uncertain usefulness. The intravenous use of acacia is a recent therapeutic procedure, and apparently sufficient time has not elapsed for the thorough appraisal of its use as a therapeutic remedy. Bearing in mind the accidents from the use of acacia that have been reported, the lack of agreement as to its beneficial effects among surgeons who have tried it, the experimental evidence that has been reported as to its deleterious effects and the paucity of data indicating its clinical usefulness, conservative practitioners will still withhold their verdict. Moreover, the questions of intravenous therapy, which are involved in any discussion on the use of acacia in shock, hemorrhage and allied conditions, are an important and serious complicating consideration.—Journal A. M. A., June 17, 1922, p. 1897.

Therapeutic Uses of Yeast—If the medical profession will assist in educational work, patent medicine exploitation of the public in the name of vitamins will undoubtedly fail. Quite a few new yeast products and other so-called vitamin extracts are being put on the market, but, on the whole, the public is not using them, and the advertising seems to be a failure. However, the matter seems sufficiently grave for the State Board of Health to issue warning to the effect that ordinary diet contains enough and more than enough vitamin for all practical purposes, and that vitamin extracts are largely inert. In the few cases in which vitamin is indicated, the vitamin carrier, like Cod Liver Oil, orange juice should be used, and no attempt made to concentrate.

Laxatives—Untoward Effects of Laxatives—Lately a number of instances of cutaneous manifestations due to the use of phenolphthalein as a laxative drug have been brought to the attention of physicians, particularly by dermatologists. Now Underhill and Errico have demonstrated that when magnesium sulphate, sodium sulphate and potassium and sodium tartrate are administered experimentally in doses capable of producing diarrhea, a distinct concentration of the blood may take place. The fact that purgatives exert a definite influence, in the direction of concentrating the blood, indicates that care should be exercised in the administration of purgatives in disease conditions, especially in those conditions known to be responsible for concentrated blood. Blood concentrated to some extent, and yet not sufficiently concentrated to be dangerous in itself, may reach a dangerous concentration by the added influence of the purgative.—Journal A. M. A., June 24, 1922, p. 1964.

VOL. XX OCTOBER, 1922 No. 10

"The Obtuse Triangle"

Chiropractic-Osteopathic-Anti-vivisection Initiatives! These three weird sisters meet again obtusely repeating the same old stories in the same old way. "Fair is foul and foul is fair" is still their campaign slogan.

In the light of well-known facts, their clamorous claims and absurd accusations of persecution, incompetency, injustice and cruelty hurled at a mythical "Medical Trust" vanish into thin air.

All three prate about "Rights." One would make the *rights of rats and guinea-pigs* superior to man, whilst the other two place the "rights" of their small groups above the majority. All three ignore paramount rights of the people and threaten to break down educational standards and vital public health safeguards. The three combined would permit the unqualified to practice unscientifically and prohibit the qualified from practicing scientifically.

This triple threat has been appropriately called "the obtuse triangle." Two members of the triangle attempt to get quickly—at the polls—what physicians and surgeons must obtain by years of study and special education. *Education Cannot Be Voted Into Them.* Alleged "graduates" of so-called colleges who fail to pass the State Examination need *More Education, Not More Examining Boards.*

All three falsely charge that those opposing these measures are inspired by selfish motives. Health Boards, hospitals, universities, research workers, clinics, laboratories, chemists, pharmacists, biologists, bacteriologists, social workers, the medical, dental, nursing, veterinary professions, et al., in the interests of public welfare, must oppose measures that would nullify educational standards, practically prohibit present scientific service and outlaw future scientific progress.

Devoted scientific men and women have built up dependable institutions and agencies to combat and conquer deadly diseases that attack man and all the living creatures over which he was given dominion. Their noble achievements, their daily curative and preventive work amply answer the obtuse proposals of this triangular combination.

No amount of lurid literature reeking with chiropractic pretense, osteopathic prejudice and anti-vivisection abuse can take the place of such scientific service.

Facts made the people defeat the Chiropractic-Osteopathic-Anti-vivisection measures at the general election in 1920 as unnecessary and unsafe legislation. *Facts* made the California Legislature repeatedly reject these measures as dangerous and destructive. We urge each voter to read the "Chiropractic-Osteopathic-Anti-vivisection Initiatives and *contrast their false issues with Facts.*

League for the Conservation of Public Health,

Balboa Building *San Francisco*

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL *is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.*

MYOCARDIAL INSUFFICIENCY.*

R. K. BARRY, M. D., San Diego.

In approaching this subject the first thing to consider is, what are the essential symptoms of myocardial insufficiency. While it is necessary in every case to recognize the evidence afforded by careful physical examination supplemented by the use of mechanical aids, it must be borne in mind that the facts when revealed do not give the information which is essential. The essential question for the physician to decide is whether the symptoms indicate the presence of an insufficient myocardium and the likelihood of heart failure. This knowledge can only be acquired in many cases by understanding what happens when the individual is engaged in some occupation that calls for some extra effort on the part of the heart. Hence all means of observation employed when the body is at rest can only yield very incomplete evidence. The kind of evidence which is essential is to be sought for in the symptoms evoked when effort is made, frequently only evoked then; as well as in the symptoms of functional insufficiency when the body is at rest. These symptoms are often so elusive and so insignificant that they readily escape the attention, while it is often difficult to appraise their value when detected. As our knowledge of what is meant by heart failure increases, the real significance of such symptoms will be revealed. Heart failure may be defined as the condition in which the heart muscle is unable to maintain an efficient circulation during the efforts necessary to the daily life of the individual.
